Features

- 2.7V to 3.6V Supply
 - Full Read and Write Operation
- Low Power Dissipation
 - 8 mA Active Current
 - 50 µA CMOS Standby Current
- Read Access Time 300 ns
- Byte Write 3 ms
- Direct Microprocessor Control
 - DATA Polling
 - READY/BUSY Open Drain Output
- High Reliability CMOS Technology
 - Endurance: 100,000 Cycles
 - Data Retention: 10 Years
- JEDEC Approved Byte-Wide Pinout
- Industrial Temperature Ranges

The AT28BV64 is a low-voltage, low-power Electrically Erasable and Programmable Read-only Memory specifically designed for battery powered applications. Its 64K of memory is organized 8,192 words by 8 bits. Manufactured with Atmel's advanced nonvolatile CMOS technology, the device offers access times to 200 ns with power dissipation less than 30 mW. When the device is deselected the standby current is less than $50~\mu A$.

The AT28BV64 is accessed like a Static RAM for the read or write cycles without the need for external components. During a byte write, the address and data are latched internally, freeing the microprocessor address and data bus for other operations. Following the initiation of a write cycle, the device will go to a busy state and automatically clear and write the latched data using an internal control timer. The device includes two methods for detecting the end of a write cycle, level detection of RDY/BUSY and DATA polling of I/O₇. Once the end of a write cycle has been detected, a new access for a read or write can begin.

Atmel's AT28BV64 has additional features to ensure high quality and manufacturability. The device utilizes error correction internally for extended endurance and for improved data retention characteristics. An extra 32-bytes of EEPROM are available for device identification or tracking.

*NOTICE:

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability

5. Device Operation

5.1 Read

The AT28BV64 is accessed like a Static RAM. When \overline{CE} and \overline{OE} are low and \overline{WE} is high, the data stored at the memory location determined by the address pins is asserted on the outputs. The outputs are put in a high impedance state whenever \overline{CE} or \overline{OE} is high. This dual line control gives designers increased flexibility in preventing bus contention.

5.2 Byte Write

Writing data into the AT28BV64 is similar to writing into a Static RAM. A low pulse on the $\overline{\text{WE}}$ or $\overline{\text{CE}}$ input with $\overline{\text{OE}}$ high and $\overline{\text{CE}}$ or $\overline{\text{WE}}$ low (respectively) initiates a byte write. The address location is latched on the falling edge of $\overline{\text{WE}}$ (or $\overline{\text{CE}}$); the new data is latched on the rising edge. Internally, the device performs a self-clear before write. Once a byte write has been started, it will automatically time itself to completion. Once a programming operation has been initiated and for the duration of t_{WC} , a read operation will effectively be a polling operation.

5.3 READY/BUSY

Pin 1 is an open drain READY/BUSY output that can be used to detect the end of a write cycle. RDY/BUSY is actively pulled low during the write cycle and is released at the completion of the write. The open drain connection allows for OR-tying of several devices to the same RDY/BUSY line.

5.4 DATA Polling

The AT28BV64 provides $\overline{\text{DATA}}$ Polling to signal the completion of a write cycle. During a write cycle, an attempted read of the data being written results in the complement of that data for I/O₇ (the other outputs are indeterminate). When the write cycle is finished, true data appears on all outputs.

5.5 Write Protection

Inadvertent writes to the device are protected against in the following ways: (a) V_{CC} sense – if V_{CC} is below 1.8V (typical) the write function is inhibited; (b) V_{CC} power on delay – once V_{CC} has reached 2.0V the device will automatically time out 10 ms (typical) before allowing a byte write; and (c) Write Inhibit – holding any one of \overline{OE} low, \overline{CE} high or \overline{WE} high inhibits byte write cycles.
