

SERIAL INTERFACE CODEC/FILTER

- COMPLETE CODEC AND FILTERING SYSTEM (DEVICE) INCLUDING:
 - Transmit high-pass and low-pass filtering.
 - Receive low-pass filter with $\sin x/x$ correction.
 - Active RC noise filters
 - μ -law or A-law compatible COder and DECoder.
 - Internal precision voltage reference.
 - Serial I/O interface.
 - Internal auto-zero circuitry.
- A-LAW 16 PINS (ETC5057FN, 20 PINS)
- μ -LAW WITHOUT SIGNALING, 16 PINS (ETC5054FN, 20 PINS)
- MEETS OR EXCEEDS ALL D3/D4 AND CCITT SPECIFICATIONS
- $\pm 5V$ OPERATION
- LOW OPERATING POWER - TYPICALLY 60 mW
- POWER-DOWN STANDBY MODE - TYPICALLY 3 mW
- AUTOMATIC POWER-DOWN
- TTL OR CMOS COMPATIBLE DIGITAL INTERFACES
- MAXIMIZES LINE INTERFACE CARD CIRCUIT DENSITY
- 0 to 70°C OPERATION

DESCRIPTION

The ETC5057/ETC5054 family consists of A-law and μ -law monolithic PCM CODEC/filters utilizing the A/D and D/A conversion architecture shown in the block diagram below, and a serial PCM interface. The devices are fabricated using double-poly CMOS process. The encode portion of each device consists of an input gain adjust amplifier, an active RC pre-filter which eliminates very high frequency noise prior to entering a switched-capacitor band-pass filter that rejects signals below 200 Hz and above 3400 Hz. Also included are auto-zero circuitry and a companding coder which samples the filtered signal and encodes it in the companded A-law or μ -law PCM format. The decode portion of each device consists of an expanding decoder, which reconstructs the analog signal from the companded A-law or μ -law code, a low-pass filter which corrects for the $\sin x/x$ response of the decoder output and rejects signals above 3400 Hz and is followed by a single-ended power amplifier capable of driving low impedance loads. The devices require 1.536 MHz, 1.544

PIN DESCRIPTION

Name	Pin Type *	N° DIP and SO	N° PLCC (**)	Function	Description
V _{BB}	S	1	1	Negative Power Supply	V _{BB} = - 5 V ± 5 %.
G _{ND} A	GND	2	2	Analog Ground	All signals are referenced to this pin.
V _{FRO}	O	3	3	Receive Filter Output	Analog Output of the Receive Filter
V _{CC}	S	4	5	Positive Power Supply	V _{CC} = + 5 V ± 5 %.
FS _R	I	5	6	Receive Frame Sync Pulse	Enables BCLK _R to shift PCM data into D _R . FS _R is an 8kHz pulse train. See figures 1, 2 and 3 for timing details.
D _R	I	6	7	Receive Data Input	PCM data is shifted into D _R following the FS _R leading edge.
BCLK _R /CLKSEL	I	7	8	Shift-in Clock	Shifts data into D _R after the FS _R leading edge. May vary from 64 kHz to 2.048 MHz. Alternatively, may be a logic input which selects either 1.536 MHz/1.544 MHz or 2.048 MHz for master clock in synchronous mode and BCLK _X is used for both transmit and receive directions (see table 1). This input has an internal pull-up.
MCLK _R /PDN	I	8	9	Receive Master Clock	Must be 1.536 MHz, 1.544 MHz or 2.048 MHz. May be asynchronous with MCLK _X , but should be synchronous with MCLK _X for best performance. When MCLK _R is connected continuously low, MCLK _X is selected for all internal timing. When MCLK _R is connected continuously high, the device is powered down.
MCLK _X	I	9	12	Transmit Master Clock	Must be 1.536 MHz, 1.544 MHz or 2.048 MHz. May be asynchronous with MCLK _R .
BCLK _X	I	10	14	Shift-out Clock	Shifts out the PCM data on D _X . May vary from 64 kHz to 2.048 MHz, but must be synchronous with MCLK _X .
D _X	O	11	15	Transmit Data Output	The TRI-STATE® PCM data output which is enabled by FS _X .
FS _X	I	12	16	Transmit Frame Sync Pulse	Enables BCLK _X to shift out the PCM data on D _X . FS _X is an 8 kHz pulse train. See figures 1, 2 and 3 for timing details.
$\overline{\text{TS}}_X$	O	13	17	Transmit Time Slot	Open drain output which pulses low during the encoder time slot. Recommended to be grounded if not used.
GS _X	O	14	18	Gain Set	Analog output of the transmit input amplifier. Used to set gain externally.
VF _{XI} ⁻	I	15	19	Inverting Amplifier Input	Inverting Input of the Transmit Input Amplifier.
VF _{XI} ⁺	I	16	20	Non-inverting Amplifier Input	Non-inverting Input of the Transmit Input Amplifier.

(*) I: Input, O: Output, S: Power Supply

(**) Pins 4,10,11 and 13 are not connected

TRI-STATE® is a trademark of National Semiconductor Corp.

FUNCTIONAL DESCRIPTION**POWER-UP**

When power is first applied, power-on reset circuitry initializes the device and places it into the power-down mode. All non-essential circuits are deactivated and the D_X and V_{FRO} outputs are put in high impedance states. To power-up the device, a logical low level or clock must be applied to the $MCLK_R/PDN$ pin and FS_X and/or FS_R pulses must be present. Thus, 2 power-down control modes are available. The first is to pull the $MCLK_R/PDN$ pin high; the alternative is to hold both FS_X and FS_R inputs continuously low. The device will power-down approximately 2 ms after the last FS_X or FS_R pulse. Power-up will occur on the first FS_X or FS_R pulse. The TRI-STATE PCM data output, D_X , will remain in the high impedance state until the second FS_X pulse.

SYNCHRONOUS OPERATION

For synchronous operation, the same master clock and bit clock should be used for both the transmit and receive directions. In this mode, a clock must be applied to $MCLK_X$ and the $MCLK_R/PDN$ pin can be used as a power-down control. A low level on $MCLK_R/PDN$ powers up the device and a high level powers down the device. In either case, $MCLK_X$ will be selected as the master clock for both the transmit and receive circuits. A bit clock must also be applied to $BCLK_X$ and the $BCLK_R/CLKSEL$ can be used to select the proper internal divider for a master clock of 1.536 MHz, 1.544 MHz or 2.048 MHz. For 1.544 MHz operation, the device automatically compensates for the 193rd clock pulse each frame. With a fixed level on the $BCLK_R/CLKSEL$ pin, $BCLK_X$ will be selected as the bit clock for both the transmit and receive directions. Table 1 indicates the frequencies of operation which can be selected, depending on the state of $BCLK_R/CLKSEL$. In this synchronous mode, the bit clock, $BCLK_X$, may be from 64 kHz to 2.048 MHz, but must be synchronous with $MCLK_X$.

Each FS_X pulse begins the encoding cycle and the PCM data from the previous encode cycle is shifted out of the enabled D_X output on the positive edge of $BCLK_X$. After 8 bit clock periods, the

TRI-STATE D_X output is returned to a high impedance state. With and FS_R pulse, PCM data is latched via the D_R input on the negative edge of $BCLK_X$ (or $BCLK_R$ if running). FS_X and FS_R must be synchronous with $MCLK_X/R$.

ASYNCHRONOUS OPERATION

For asynchronous operation, separate transmit and receive clocks may be applied, $MCLK_X$ and $MCLK_R$ must be 2.048 MHz for the ETC5057, or 1.536 MHz, 1.544 MHz for the ETC5054, and need not be synchronous. For best transmission performance, however, $MCLK_R$ should be synchronous with $MCLK_X$, which is easily achieved by applying only static logic levels to the $MCLK_R/PDN$ pin. This will automatically connect $MCLK_X$ to all internal $MCLK_R$ functions (see pin description). For 1.544 MHz operation, the device automatically compensates for the 193rd clock pulse each frame. FS_X starts each encoding cycle and must be synchronous with $MCLK_X$ and $BCLK_X$. FS_R starts each decoding cycle and must be synchronous with $BCLK_R$. $BCLK_R$ must be a clock, the logic levels shown in table 1 are not valid in asynchronous mode. $BCLK_X$ and $BCLK_R$ may operate from 64 kHz to 2.048 MHz.

SHORT FRAME SYNC OPERATION

The device can utilize either a short frame sync pulse or a long frame sync pulse. Upon power initialization, the device assumes a short frame mode. In this mode, both frame sync pulses, FS_X and FS_R , must be one bit clock period long, with timing relationships specified in figure 2. With FS_X high during a falling edge of $BCLK_X$ the next rising edge of $BCLK_X$ enables the D_X TRI-STATE output buffer, which will output the sign bit. The following seven rising edges clock out the remaining seven bits, and the next falling edge disables the D_X output. With FS_R high during a falling edge of $BCLK_R$ ($BCLK_X$ in synchronous mode), the next falling edge of $BCLK_R$ latches in the sign bit. The following seven falling edges latch in the seven remaining bits. Both devices may utilize the short frame sync pulse in synchronous or asynchronous operating mode.

LONG FRAME SYNC OPERATION

To use the long frame mode, both the frame sync pulses, FS_X and FS_R , must be three or more bit clock periods long, with timing relationships specified in figure 3. Based on the transmit frame sync, FS_X , the device will sense whether short or long frame sync pulses are being used. For 64 kHz operation, the frame sync pulse must be kept low for a minimum of 160 ns (see fig. 1). The D_X TRI-STATE output buffer is enabled with the rising edge of FS_X or the rising edge of $BCLK_X$, whichever comes later, and the first bit clocked out is the sign bit. The following seven $BCLK_X$ rising

Table 1: Selection of Master Clock Frequencies.

$BCLK_R/CLKSEL$	Master Clock Frequency Selected	
	ETC5057	ETC5054
Clocked	2.048 MHz	1.536 MHz or 1.544 MHz
0	1.536 MHz or 1.544 MHz	2.048 MHz
1 (or open circuit)	2.048 MHz	1.536 MHz or 1.544 MHz

edges clock out the remaining seven bits. The D_X output is disabled by the falling $BCLK_X$ edge following the eighth rising edge, or by FS_X going low, whichever comes later. A rising edge on the receive frame sync pulse, FS_R , will cause the PCM data at D_R to be latched in on the next eight falling edges of $BCLK_R$ ($BCLK_X$ in synchronous mode). Both devices may utilize the long frame sync pulse in synchronous or asynchronous mode.

TRANSMIT SECTION

The transmit section input is an operational amplifier with provision for gain adjustment using two external resistors, see figure 6. The low noise and wide bandwidth allow gains in excess of 20 dB across the audio passband to be realized. The op amp drives a unitygain filter consisting of R_D active pre-filter, followed by an eighth order switched-capacitor bandpass filter clocked at 256 kHz. The output of this filter directly drives the encoder sample-and-hold circuit. The A/D is of companding type according to A-law (ETC5057) or μ -law (ETC5054) coding conventions. A precision voltage reference is trimmed in manufacturing to provide an input overload (t_{MAX}) of nominally 2.5V peak (see table of transmission characteristics). The FS_X frame sync pulse controls the sampling of the filter output, and then the successive-ap-

proximation encoding cycle begins. The 8-bit code is then loaded into a buffer and shifted out through D_X at the next FS_X pulse. The total encoding delay will be approximately 165 μ s (due to the transmit filter) plus 125 μ s (due to encoding delay), which totals 290 μ s. Any offset voltage due to the filters or comparator is cancelled by sign bit integration.

RECEIVE SECTION

The receive section consists of an expanding DAC which drives a fifth order switched-capacitor low pass filter clocked at 256 kHz. The decoder is A-law (ETC5057) or μ -law (ETC5054) and the 5th order low pass filter corrects for the $\sin x/x$ attenuation due to the 8 kHz sample and hold. The filter is then followed by a 2nd order RC active post-filter and power amplifier capable of driving a 600 Ω load to a level of 7.2 dBm. The receive section is unity-gain. Upon the occurrence of FS_R , the data at the D_R input is clocked in on the falling edge of the next eight $BCLK_R$ ($BCLK_X$) periods. At the end of the decoder time slot, the decoding cycle begins, and 10 μ s later the decoder DAC output is updated. The total decoder delay is $\sim 10\mu$ s (decoder update) plus 110 μ s (filter delay) plus 62.5 μ s (1/2 frame), which gives approximately 180 μ s. A mute circuitry is active during 10ms when power up.

ABSOLUTE MAXIMUM RATINGS

DISTORTION

Symbol	Parameter	Min.	Typ.	Max.	Unit
STD _X or STD _R	Signal to Total Distortion (sinusoidal test method) Transmit or Receive Half-channel Level = 3.0dBm0 Level = 0dBm0 to -30dBm0 Level = -40dBm0 XMT RCV XMT RCV Level = -55dBm0	 33 36 29 30 14 15			dBp
SFD _X	Single Frequency Distortion, Transmit (T _A = 25°C)			-46	dB
SFD _R	Single Frequency Distortion, Receive (T _A = 25°C)			-46	dB
IMD	Intermodulation Distortion Loop Around Measurement, VFXI+ = -4dBm0 to -21dBm0, two Frequencies in the Range 300Hz - 3400Hz			-41	dB

CROSSTALK

Symbol	Parameter	Min.	Typ.	Max.	Unit
CT _{X-R}	Transmit to Receive Crosstalk, 0 dBm0 Transmit Level f = 300Hz to 3400Hz, D _R = Steady PCM Mode		- 90	- 75	dB
CT _{R-X}	Receive to Transmit Crosstalk, 0 dBm0 Receive Level f = 300Hz to 3400Hz, (note 2)		- 90	- 70	dB

Notes:

- 1) Measured by extrapolation from distortion test results.
- 2) PPSR_X, NPSR_X, CT_{R-X} is measured with a -50dBm0 activating signal applied at VFXI⁺.

APPLICATION INFORMATION**POWER SUPPLIES**

While the pins at the ETC505X family are well protected against electrical misuse, it is recommended that the standard CMOS practice be followed, ensuring that ground is connected to the device before any other connections are made. In applications where the printed circuit board may be plugged into a "hot" socket with power and clocks already present, an extra long ground pin in the connector should be used.

All ground connections to each device should meet at a common point as close as possible to the GNDA pin. This minimizes the interaction of ground return currents flowing through a common bus impedance. 0.1µF supply decoupling capacitors should be connected from this common ground point to V_{CC} and V_{BB} as close to the device as possible.

For best performance, the ground point of each CODEC/FILTER on a card should be connected to a common card ground in star formation, rather than via a ground bus. This common ground point should be decoupled to V_{CC} and V_{BB} with 10µF capacitors.

Figure 4: T-PAD Attenuator

$$R1 = Z1 \left(\frac{N^2 + 1}{N^2 - 1} \right) - 2 \sqrt{Z1 \cdot Z2} \left(\frac{N}{N^2 - 1} \right)$$

$$R2 = 2 \sqrt{Z1 \cdot Z2} \left(\frac{N}{N^2 - 1} \right)$$

$$\text{Where: } N = \sqrt{\frac{\text{POWERIN}}{\text{POWEROUT}}}$$

$$\text{and: } S = \sqrt{\frac{Z1}{Z2}}$$

$$\text{Also: } Z = \sqrt{Z_{SC} \cdot Z_{OC}}$$

Where Z_{SC} = impedance with short circuit termination and Z_{OC} = impedance with open circuit termination.

Figure 5: Π-PAD Attenuator

$$R3 = \sqrt{\frac{Z1 \cdot Z2}{2}} \left(\frac{N^2 - 1}{N} \right)$$

$$R3 = Z1 \left(\frac{N^2 - 1}{N^2 - 2NS + 1} \right)$$

RECEIVE GAIN ADJUSTMENT

For applications where a ETC505X family CODEC/filter receive output must drive a 600Ω load, but a peak swing lower than ± 2.5V is required, the receive gain can be easily adjusted by inserting a matched T-pad or π –pad at the output. Table II lists the required resistor values for 600Ω terminations. As these are generally non-standard values, the equations can be used to compute the attenuation of the closest practical set of resistors. It may be necessary to use unequal values for the R1 or R4 arms of the attenuators to achieve a precise attenuation. Generally it is tolerable to allow a small deviation of the input impedance from nominal while still maintaining a good return loss. For example a 30dB return loss against 600Ω is obtained if the output impedance of the attenuator is in the range 282Ω to 319Ω (assuming a perfect transformer).

Table 2 : Attenuator Tables For
Z1 = Z2 = 300 Ω (all values in Ω).
