

CMOS 8-BIT MICROCONTROLLER

TMP87C409N, TMP87C409M, TMP87C809N, TMP87C809M

The 87C409/809 are the high speed and high performance 8-bit single chip microcomputers. These MCU contain CPU core, ROM, RAM, input/output ports, three multi-function timer/counters, a 10-bit A/D converter, on a chip. The 87C409/809 provide high current output capability for LED direct drive.

Part No.	ROM	RAM	Package	OTP MCU
* TMP87C409N	4K × 8-bit	256 × 8-bit	SDIP28-P-400-1.78	* TMP87P809N
* TMP87C409M			SOP28-P-450-1.27	* TMP87P809M
* TMP87C809N	8K × 8-bit	256 × 8-bit	SDIP28-P-400-1.78	* TMP87P809N
* TMP87C809M			SOP28-P-450-1.27	* TMP87P809M

* : UNDER DEVELOPMENT

FEATURES

- ◆ 8-bit single chip microcomputer TLCS-870 Series
- ◆ instruction execution time: 0.5 us (at 8 MHz)
- ◆ 412 basic instruction
 - Multiplication and Division (8bits × 8bits, 16bits ÷ 8bits)
 - Bit manipulations (Set/Clear/Complement/Load/Store/Test/Exclusive or)
 - 16-bit data operations
 - 1-byte jump/subroutine-call (Short relative jump/Vector call)
- ◆ 11 interrupt sources (External:4, Internal:7)
 - All sources have independent latches each, and nested interrupt control is available.
 - 2 edge-selectable external interrupts with noise reject.
 - High-speed task switching by register bank changeover
- ◆ 3 Input/Output ports (22pins)
 - High current output: 6pins (Typ. 20 mA)
- ◆ 16-bit Timer/Counter
 - Timer, Event counter modes
- ◆ Two 8-bit Timer/Counters
 - Timer, Event counter, Capture (Pulse width/duty measurement), PWM output, Programmable divider output modes.
- ◆ Time Base Timer (Interrupt frequency: 1 Hz to 16 kHz)
- ◆ Divider output function (frequency: 1 kHz to 8 kHz)
- ◆ Watch dog Timer
- ◆ Serial bus Interface (SBI-ver. B)
 - I²C-bus, 8-bit SIO modes.
- ◆ 10-bit successive approximate type A/D converter
 - 8 analog inputs
- ◆ Two Oscillation Stop Detector outputs (High-impedance output)
- ◆ Two Power saving operating modes
 - STOP mode: Oscillation stops. Battery/Capacitor back-up. Port output hold/high-impedance.
 - IDLE mode: CPU stops, and Peripherals operate using high-frequency clock. Release by interrupts.
- ◆ Wide operating voltage: 2.2 to 5.5V at 4.2 MHz/4.5 to 5.5V at 8 MHz
- ◆ Emulation Pod: BM87C809N0A

Purchase of TOSHIBA I²C components conveys a license under the Philips I²C Patent Rights to use these components in an I²C system, provided that the system conforms to the I²C Standard Specification as defined by Philips.

PIN ASSIGNMENTS (TOP VIEW)

SDIP28-P-400-1.78/SOP28-P-450-1.27

BLOCK DIAGRAM

PIN FUNCTION

Pin Name	Input / Output	Function	
P17~ P16	I/O	8-bit programmable input/output ports (tri-state).	
P13 ($\overline{\text{DVO}}$)	I/O (Output)	Each bit of the port can be individually configured as an input or an output under software control.	Divider output
P12 (TC1)	I/O (Input)	When used as an external input or a timer counter input, the input mode is configured. When used as a divider output, the latch must be set to "1".	Timer/Counter 1 input
P11 (INT1)			External interrupt input 1
P10 ($\overline{\text{INT0}}$)			External interrupt input 0
P43 ($\overline{\text{STOP/INT5}}$)	I/O (Input/Input)	4-bit input/output port with latch (high current output).	STOP mode release input/External interrupt 5 input
P42 (SDA/SO)	I/O (I/O/Output)	When used as an input port, an I ² C input/output or an external interrupt input the latch must be set to "1".	I ² C bus serial data input/output or SIO serial data output
P41 (SCL/SI)	I/O (I/O/Input)		I ² C bus serial clock input/output or SIO serial data input
P40 ($\overline{\text{SCK}}$)	I/O (I/O)		SIO serial clock input/output
P51 (TC4/PWM/PDO/CLZ1)	I/O (Input/Output /Output/Output))	2-bit programmable input/output ports (tri-state, high current output). Each bit of the port can be individually configured as an input or an output under software control.	Timer/counter 4 input or 8-bit PWM output or 8-bit PDO output or oscillation stop detector output 1
P50 (TC3/INT3/CLZ0)	I/O (Input/Input /Output)	When used as a timer counter input or an external interrupt input the input mode is configured. When used as a PWM/PDO output, the latch must be set to "1" and the output mode is configured. When used as a oscillation stop detector output, the output mode is configured.	Timer/counter 3 input or external interrupt input 3 or oscillation stop detector output 0
P67 (AIN7/VAREF)	I/O (Input/Input)	8-bit programmable input/output ports (tri-state). Each bit of the port can be individually configured as an input or an output under software control.	A/D converter analog input or analog reference power supply
P66 (AIN6)~P60 (AIN0)	I/O (Input)	When used as an analog input or an analog reference power supply, the input mode is configured.	A/D converter analog inputs
XIN, XOUT	Input.Output	Resonator connecting pins for high-frequency clock. For inputting external clock, XIN is used and XOUT is open.	
$\overline{\text{RESET}}$	Input	Reset signal input.	
TEST	Input	Test pint for out-going test. Be tied to low.	
VDD (VAREF)	Power Supply	+ 5V	Analog reference power supply
VSS (VASS)		0 V (GND)	Analog reference GND

OPERATIONAL DESCRIPTION

1. CPU CORE FUNCTIONS

The CPU core consists of a CPU, a system clock controller, an interrupt controller, and a watchdog timer. This section provides a description of the CPU core, the program memory, the data memory, and the reset circuit.

1.1 Memory Address Map

The TMP87C409/809 are capable of addressing 64K bytes of memory. Figure 1-1 shows the memory address maps of the 87C409/809. In the TMP87C409/809 the memory is organized 3 address spaces (ROM, RAM and SFR). It uses a memory mapped I/O system, and all I/O registers are mapped in the SFR address spaces. There are 16 banks of general-purpose registers. The register banks are also assigned to the RAM address space.

Figure 1-1. Memory Address Map

1.2 Program Memory (ROM)

The 87C409 has a 4K bytes (addresses F000 to FFFF_H), the 87C809 has a 8K bytes (address E000 to FFFF_H) of program memory (mask programmed ROM). Figure 1-2 shows a program memory map.

Addresses FF00 to FFFF_H of program memory is also used for a special purpose.

(1) Interrupt vector table (addresses FFE0 to FFFF_H)

This table consists of a reset vector and 16 interrupt vectors (2 bytes/vector). These vectors store a reset start address and interrupt service routine entry addresses.

(2) Vector table for vector call instructions (addresses FFC0 to FFDF_H)

This table stores call vectors (subroutine entry address, 2 bytes/vector) for the vector call instructions [CALLV a]. There are 16 vectors. The CALLV instruction increases memory efficiency when utilized for frequently used subroutine calls (called from 3 or more locations).

(3) Entry area (addresses FF00 to FFFF_H) for page call instructions

This is the subroutine entry address area for the page call instructions [CALLP a]. Addresses FF00 to FFBF_H are normally used because addresses FFC0 to FFFF_H are used for the vector tables.

Programs and fixed data are stored in the program memory. The instruction to be executed next is read from the address indicated by the current contents of the program counter (PC). There are relative jump and absolute jump instructions. The concepts of page or bank boundaries are not used in the program memory concerning any jump instruction.

Example : The relationship between the jump instructions and the PC.

① 5-bit PC-relative jump [JRS cc, \$ + 2 + d]

F8C4H: JRS T, \$ + 2 + 08H

When JF = 1, the jump is made to F8CE_H, which is 08_H added to the contents of the PC. (The PC contains the address of the instruction being executed + 2; therefore, in this case, the PC contents are F8C4_H + 2 = F8C6_H.)

② 8-bit PC-relative jump [JR cc, \$ + 2 + d]

F8C4H: JR Z, \$ + 2 + 80H

When ZF = 1, the jump is made to F846_H, which is FF80_H (-128) added to the current contents of the PC.

③ 16-bit absolute jump [JP a]

F8C4H: JP 0F235H

An unconditional jump is made to address F235_H. The absolute jump instruction can jump anywhere within the entire 64K-bytes space.

Figure 1-2. Program Memory Map

In the TLCS-870 Series, the same instruction used to access the data memory is also used to read out fixed data stored in the program memory. The register offset PC-relative addressing ($PC + A$) instructions can also be used, and the code conversion, table look-up and n-way multiple jump processing can easily be programmed.

Example 1 : Loads the ROM contents at the address specified by the HL register pair contents into the accumulator (87C809 : $HL \geq E000_H$)

```
LD      A, (HL)          ; A ← ROM (HL)
```

Example 2 : Converts BCD to 7-segment code (common anode LED). When $A = 05_H$, 92_H is output to port P1 after executing the following program.

```
ADD     A, TABLE - $ - 4    ; P1 ← ROM (TABLE + A)
```

```
LD      (P1), (PC + A)
```

```
JRS     T, SNEXT            ; Jump to SNEXT
```

```
TABLE : DB    0C0H, 0F9H, 0A4H, 0B0H, 99H, 92H, 82H, 0D8H, 80H, 98H
```

```
SNEXT :
```

Notes : "\$" is a header address of ADD instruction. DB is a byte data definition instruction.

Example 3 : N-way multiple jump in accordance with the contents of accumulator ($0 \leq A \leq 3$).

```
SHLC     A                  ; if A = 00_H then PC ← F234_H
```

```
JP       (PC + A)           if A = 01_H then PC ← F378_H
```

```
if A = 02_H then PC ← FA37_H
```

```
if A = 03_H then PC ← F1B0_H
```

```
DW       0F234H, 0F378H, 0FA37H, 0F1B0H
```

Notes : DW is a word data definition instruction. Word = 2 bytes.

1.3 Program Counter (PC)

The program counter (PC) is a 16-bit register which indicates the program memory address where the instruction to be executed next is stored. After reset, the reset vector stored in the vector table (addresses FFFF and FFFE_H) is loaded into the PC; therefore, program execution is possible from any desired address. For example, when F0 and 3E_H are stored at addresses FFFF and FFFE_H, respectively, the execution starts from address F03E_H after reset.

The TLCS-870 Series utilizes pipelined processing (instruction pre-fetch); therefore, the PC always indicates 2 addresses in advance. For example, while a 1-byte instruction stored at address F123_H is being executed, the PC contains F125_H.

Figure 1-3. Program Counter

1.4 Data Memory (RAM)

The 87C409/809 have 256 bytes (addresses 0040 to 013F_H) of data memory (static RAM). Figure 1.4 shows the data memory map.

Addresses 0000 to 00FF_H are used as a direct addressing area to enhance instructions which utilize this addressing mode; therefore, addresses 0040 to 00FF_H in the data memory can also be used for user flags or user counters.

Example 1 : If bit 2 at data memory address 00C0_H is "1", 00_H is written to data memory at address 00E3_H; otherwise, FF_H is written to the data memory at address 00E3_H.

```

TEST    (00C0H).2      ; if (00C0H)2 = 0 then jump
JRS     T,SZERO
CLR     (00E3H)         ; (00E3H) ← 00H
JRS     T,SNEXT
SZERO : LD    (00E3H), 0FFH ; (00E3H) ← FFH
SNEXT :
```

Example 2 : Increments the contents of data memory at address 00F5_H, and clears to 00_H when 10_H is exceeded.

```

INC     (00F5H)
AND     (00F5H), 0FH
```

General-purpose register banks (8 registers × 16 banks) are also assigned to the 128 bytes of addresses 0040 to 00BF_H. Access as data memory is still possible even when being used for registers. For example, when the contents of the data memory at address 0040_H is read out, the contents of the accumulator in the bank 0 are also read out.

The stack can be located anywhere within the data memory except the register bank area. For more details on the stack, see section "1.7 Stack and Stack Pointer".

With the TLCS-870 Series, programs in data memory cannot be executed. If the program counter indicates a data memory address (addresses 0040 to 013F_H), an address-trap-reset is generated due to bus error. (Internal reset is occurred)

The data memory contents become unstable when the power supply is turned on; therefore, the data memory should be initialized by an initialization routine.

Example 1 : Clears RAM to 0 except the bank 0

```

LD      HL, 0048H      ; Sets start address to HL register pair
LD      A, H           ; Sets initial data (A)
LD      BC, 00F7H      ; Sets number of byte to BC register pair
SRAMCLR: LD    (HL+), A
DEC     BC
JRS     F, SRAMCLR
```

Note : "\$" is a header address of ADD instruction. The general-purpose registers are mapped in the RAM; therefore, do not clear RAM at the current bank addresses. Clears RAM to 0 except the bank 0.

Figure 1-4. Data Memory Map

1.5 General-purpose Register Banks

General-purpose registers are mapped into addresses 0040 to 00BF_H in the data memory. There are 16 register banks, and each bank contains eight 8-bit registers W, A, B, C, D, E, H, and L. Figure 1-5 shows the general-purpose register bank configuration. The unused register banks can be used as a data memory.

Figure 1-5. General-purpose Register Banks

In addition to access in 8-bit units, the registers can also be accessed in 16-bit units as the register pairs WA, BC, DE, and HL. Besides its function as a general-purpose register, the register also has the following functions.

(1) A, WA

The A register functions as an 8-bit accumulator and WA the register pair functions as a 16-bit accumulator (W is high byte and A is low byte). Registers other than A can also be used as accumulators for 8-bit operations.

Examples :

①	ADD A, B	; Adds B contents to A contents and stores the result into A.
②	SUB WA, 1234H	; Subtracts 1234 _H from WA contents and stores the result into WA.
③	SUB E, A	; Subtracts A contents from B contents, and stores the result into E.

(2) HL, DE

The HL register functions as a data pointer/index register/base register, and the DE register pair function as a data pointer to specify the memory address.

HL also has an auto-post-increment and auto-pre-decrement functions. This function simplifies multiple digit data processing, software LIFO (last-in first-out) processing, etc.

Example 1 :

①	LD A, (HL)	; Loads the memory contents at the address specified by HL into A.
②	LD A, (HL + 52H)	; Loads the memory contents at the address specified by the value obtained by adding 52 _H to HL contents into A.
③	LD A, (HL + C)	; Loads the memory contents at the address specified by the value obtained by adding the register C contents to HL contents into A.
④	LD A, (HL +)	; Loads the memory contents at the address specified by HL into A. Then increments HL.
⑤	LD A, (- HL)	; Decrement HL. Then loads the memory contents at the address specified by new HL into A.

TLCS-870 Series can transfer data directly memory to memory, and operate directly between memory data and memory data. This facilitates the programming of block processing.

Example 2 : Block transfer

	LD B, m	; m = n - 1 (n : Number of bytes to transfer)
	LD HL, DSTA	; Sets destination address
	LD DE, SRCA	; Sets source address
SLOOP :	LD (HL), (DE)	; (HL) ← (DE)
	INC HL	; HL ← HL + 1
	INC DE	; DE ← DE + 1
	DEC B	; B ← B - 1
	JRS F, SLOOP	; if B ≥ 0 then loop

(3) B, C, BC

Registers B and C can be used as 8-bit buffers or counter, and the BC register pair can be used as a 16-bit buffer or counter. The C register functions as an offset register for register offset index addressing (refer to example 1 ③ above) and as a divisor register for the division instruction.

Example 1 : Repeat processing

	LD B, n	; Sets n as the number of repetitions
SREPEAT :	processing	
	DEC B	
	JRS F, SREPEAT	

Example 2 : Division (16-bit ÷ 8-bit)

DIV	WA, C	; Divides the WA contents by the C contents, places the quotient in A and the remainder in W.
-----	-------	---

The general-purpose banks are selected by the 4-bit register bank selector (RBS). During reset, the RBS is initialized to "0". The bank selected by the RBS is called the current bank.

Together with the flag, the RBS is assigned to address 003FH in the SFR as the program status word (PSW). There are 3 instructions [LD RBS, n], [PUSH PSW], [POP PSW] to access the PSW. The PSW can be also operated by the memory access instruction.

Example 1 : Incrementing the RBS

```
INC (003FH) ; RBS ← RBS + 1
```

Example 2 : Reading the RBS

```
LD A, (003FH) ; A ← RBS (The flags are simultaneously read in this instruction.)
```

Highly efficient programming and high speed task switching are possible by using bank changeover to save registers during interrupt and to transfer parameters during subroutine processing. During interrupt, the RBS is automatically saved onto the stack. The bank used before the interrupt is automatically restored by executing an interrupt return instruction [RETI]/[RETN] ; therefore, there is no need for the RBS save/restore software processing.

The TLC8-870 Series supports a maximum of 15 interrupt sources. One bank is assigned to the main program, and one bank can be assigned to each source. Also, to increase the efficiency of data memory usage, assign the same bank to interrupt sources which are not nested.

Example : Saving/restoring registers during interrupt task using bank changeover.

```
PINT1 : LD RBS, n ; RBS ← n (Bank changeover)
        [Interrupt processing]
        RETI ; Maskable interrupt return (Bank automatic restoring)
```

1.6 Program Status Word (PSW)

The program status word (PSW) consists of a register bank selector (RBS) and flags, and the PSW is assigned to address 003FH in the SFR.

The RBS can be read and written using the memory access instruction, however the flags can only be read. When writing to the PSW, the change specified by the instruction is made without writing data to the flags. For example, when the instruction [LD (003FH), 05H] is executed, "5" is written to the RBS and the JF is set to "1", but the other flags are not affected.

During interrupt, PSW is saved to the stack with the program counter. The PSW is restored from the stack by executing return instructions [RETI]/[RETN].

[PUSH PSW] and [POP PSW] are the PSW access instructions.

1.6.1 Register Bank Selector (RBS)

The register bank selector (RBS) is a 4-bit register used to select general-purpose register banks. For example, when RBS = 2, bank 2 is currently selected. During reset, the RBS is initialized to "0".

Figure 1-6. PSW (Flags, RBS) Configuration

1.6.2 Flags (FLAG)

The flags are configured with the upper 4 bits : a zero flag, a carry flag, a half carry flag and a jump status flag. The flags are set or cleared under conditions specified by the instruction. These flags except the half carry flag are used as jump condition "cc" for conditional jump instructions [JR cc, \$ + 2 + d], [JRS cc, \$ + 2 + d]. After reset, the jump status flag is initialized to "1", other flags are not affected.

(1) Zero flag (ZF)

The ZF is set to "1" if the operation result or the transfer data is 00_H (for 8-bit operations and data transfers)/0000_H (for 16-bit operations); otherwise the ZF is cleared to "0".

During the bit manipulation instructions, the ZF is cleared to "0" if the contents of the specified bit is "1". This flag is set to "1" when the upper 8 bits of the product are 00_H during the multiplication instruction, and when 00_H for the remainder during the division instruction; otherwise it is cleared to "0".

(2) Carry flag (CF)

The CF is set to "1" when a carry occurred during addition or a borrow occurred during subtraction; otherwise the CF is cleared to "0". During division, this flag is set to "1" when the divisor is 00_H (divided by zero error), or when the quotient is 100_H or higher (quotient-overflow error). The CF is also affected during the shift/rotate instructions. The data shifted out from a register is set to the CF. This flag is also a 1-bit register (a boolean accumulator) for the bit manipulation instructions.

Set/clear/invert are possible with the CF manipulation instructions.

Example : Bit manipulation (The result of exclusive-OR between bit 5 content of address 07_H and bit 0 content of address 9A_H is written to bit 2 of address 01_H.)

```
LD      CF, (0007H) . 5      ; (0001H)2 ← (0007H)5 ∨ (009AH)0
XOR     CF, (009AH) . 0
LD      (0001H) . 2, CF
```

(3) Half carry flag (HF)

The HF is set to "1" when a carry occurred to bit 4 of the operation result during an 8-bit addition, or when a borrow occurred from bit 4 of the result during an 8-bit subtraction. This flag is useful in the decimal adjustment for BCD operations (adjustments using the [DAA r], or [DAS r] instructions).

Example : BCD operation

(The A becomes 47_H after executing the following program when A = 19_H, B = 28_H.)

```
ADD     A, B                ; A ← 41H, HF ← 1, CF = 0
DAA     A                   ; A ← 41H + 06H = 47H (decimal-adjust)
```

(4) Jump status flag (JF)

The JF is usually set to "1". Zero or carry information is set to the JF after operation. The JF provides the jump condition for conditional jump instructions [JR T/F, \$ + 2 = d], [JRS T/F, \$ + 2 + d] (T or F is a condition code).

Example : Jump status flag and conditional jump instruction

```
INC     A
JRS     T, SLABLE1          ; Jump when a carry is caused by the immediately
:                                     preceding operation instruction.
LD      A, (HL)
JRS     T, SLABLE2          ; JF is set to "1" by the immediately preceding
:                                     instruction, making it an unconditional jump
:                                     instruction.
```

Example : The accumulator and flags becomes as shown below after executing the following instructions when the WA register pair, the HL register pair, the data memory at address 00C5_H, the carry flag and the half carry flag contents being "219A_H", "00C5_H", "D7_H", "1", and "0", respectively.

Instruction	Accumulator after execution	Flag after execution			
		JF	ZF	CF	HF
ADDC A, (HL)	72	1	0	1	1
SUBB A, (HL)	C2	1	0	1	0
CMP A, (HL)	9A	0	0	1	0
AND A, (HL)	92	0	0	1	0
LD A, (HL)	D7	1	0	1	0
ADD A, 66H	00	1	1	1	1

Instruction	Accumulator after execution	Flag after execution			
		JF	ZF	CF	HF
INC A	9B	0	0	1	0
ROL A	35	1	0	1	0
ROR A	CD	0	0	0	0
ADD WA, 0F508H	16A2	1	0	1	0
MUL W, A	13DA	0	0	1	0
SET A.5	BA	1	1	1	0

1.7 Stack, Stack Pointer

1.7.1 Stack

The stack provides the area in which the return address or status, etc. are saved before a jump is performed to the processing routine during the execution of a subroutine call instruction or the acceptance of an interrupt.

On a subroutine call instruction [CALL a] / [CALLP a] / [CALLVn], the return address is saved (the upper byte is pushed first, followed by the lower byte). During software interrupt instruction [SWI] execution or interrupt, the program status word is saved, then the return address is saved.

When returning from the processing routine, executing a subroutine return instruction [RET] restores the contents to the PC from the stack; executing an interrupt return instruction [RETI] / [RETN] restores the contents to the PC and the PSW.

The stack can be located anywhere within the data memory.

1.7.2 Stack Pointer (SP)

The stack pointer (SP) is a 16-bit register to point out the first start address on the stack. The SP is post-decrement when a subroutine call or a push instruction is executed, or when an interrupt is accepted; and the SPC is pre-incremented when a return or a pop instruction is executed. The stack deepens to the direction of the lower address. Figure 1-8 shows the change of the stack access and the SP.

The SP is not initialized hardware-wise but requires initialization by an initialize routine (sets the highest stack address). [LD SP, mn], [LD SP, gg] and [LD gg, SP] are the SP access instructions (mn; 16-bit immediate data, gg; register pair).

Figure 1-7. Stack Pointer

Example 1 : To initialize the SP

```
LD      SP, 013FH      ; SP ← 013FH
```

Example 2 : TO read the SP

```
LD      HL, SP          ; HL ← SP
```

Figure 1-8. Stack

1.8 System Clock Controller

The system clock controller consists of a clock generator, a timing generator, and a stand-by controller.

Figure 1-9. System Clock Controller

1.8.1 Clock Generator

The clock generator generates the basic clock which provides the system clocks supplied to the CPU core and peripheral hardware.

The high-frequency (f_c) clocks can be easily obtained by connecting a resonator between the XIN/XOUT pins. Clock input from an external oscillator is also possible.

Figure 1-10. Example of Resonator Connection

Note : *Accurate Adjustment of the Oscillation Frequency :*

Although no hardware to externally and directly monitor the basic clock pulse is provided, the oscillation frequency can be adjusted by making the program to output fixed frequency pulses to the port while disabling all interrupts and monitoring this pulse. With a system requiring adjustment of the oscillation frequency, the adjusting program must be created beforehand.

1.8.2 Timing Generator

The timing generator generates from the basic clock the various system clocks supplied to the CPU core and peripheral hardware. The timing generator provides the following functions:

- ① Generation of main system clock
- ② Generation of divider output ($\overline{DVO}$) pulses
- ③ Generation of source clocks for time base timer
- ④ Generation of source clocks for watchdog timer
- ⑤ Generation of internal source clocks for timer/counters
- ⑥ Generation of internal serial clock of serial interface
- ⑦ Generation of warm-up clocks for releasing STOP mode

(1) Configuration of Timing Generator

The timing generator consists of a 21-stage divider with a divided-by-2 prescaler. During reset and at releasing STOP mode, the divider is cleared to "0", however; the prescaler is not cleared.

Note : *Even if the main system clock is changed by the clock gear, the output from the divider is not changed. The peripheral circuit using high-speed divider output (1st output) can not be used when the main system clock slows down.*

Figure 1-11. Configuration of Timing Generator

(2) Machine Cycle

Instruction execution and built-in hardware operation are synchronized with the system clock.

The minimum instruction execution unit is called a "machine cycle". There are a total of 10 different types of instructions for the TLC8-870 Series: ranging from 1-cycle instructions which require one machine cycle for execution to 10-cycle instructions which require 10 machine cycles for execution.

A machine cycle consists of 4 states (S0 to S3), and each state consists of one main system clock.

Figure 1-12. Machine Cycle

1.8.3 Stand-by Controller

The stand-by controller starts and stops the oscillation circuits. These modes are controlled by the system control registers (SYSCR1, SYSCR2). Figure 1.13 shows the operating mode transition diagram and Figure 1.14 shows the system control registers. Either the single-clock or the dual-clock mode can be selected by an option during reset.

(1) Operation mode

- ① NORMAL mode
- In this mode, both the CPU core and on-chip peripherals operate. The TMP87C409/809 are placed in this mode after reset.
- ② IDLE mode
- In this mode, the CPU and the watchdog timer are halted; however, on-chip peripherals remain active. IDLE mode is started by the system control register 2, and IDLE mode is released to NORMAL mode by an interrupt request from on-chip peripherals or external interrupt inputs. When IMF (interrupt master enable flag) is "1" (interrupt enable), the execution will resume upon acceptance of the interrupt, and the operation will return to normal after the interrupt service is completed. When IMF is "0" (interrupt disable), the execution will resume with the instruction which follows IDLE mode start instruction.
- ③ STOP mode
- In this mode, the internal oscillation circuit is turned off, causing all system operations to be halted. The internal status immediately prior to the halt is held with the lowest power consumption during this mode. The output status of input output ports can be set to either output hold or high-impedance under software control
- STOP mode is started by the system control register 1, and STOP mode is released by STOP input pin (either level-sensitive or edge-sensitive can be selected). After the warming-up period is completed, the execution resumes with the next instruction which follows the STOP mode start instruction.

Figure 1-13. Operating Mode Transition Diagram

System Control Register 1

SYSCR1 (0038 _H)	7	6	5	4	3	2	1	0	
	STOP	RELM	0	OUTEN	WUT				

(Initial value : 0000 00**)

STOP	STOP mode start	0 : CPU core and peripherals remain active 1 : CPU core and peripherals are halted	R/W
RELM	Release method for STOP mode	0 : $\overline{\text{STOP}}$ pin input rising edge release 1 : $\overline{\text{STOP}}$ pin input "H" level release	
OUTEN	Port output control during STOP mode	0 : High-impedance 1 : Remain unchanged	
WUT	Warming-up time at releasing STOP mode	00 : $3 \times 2^{19} / f_c$ 01 : $2^{19} / f_c$ 10 : $3 \times 2^{12} / f_c$ 11 : $2^{12} / f_c$	

Note 1 : Always set bit 5 to "0".

Note 2 : Bits 1, 0 in SYSCR1 is read in as undefined value when a read instruction is executed.

Note 3 : f_c ; clock [Hz]

* ; don't care

Note 4 : When the STOP mode is started by specifying OUTEN = "0", the internal input of port is fixed to "0" and the interrupt of the falling edge may be set.

System Control Register 2

SYSCR2 (0039 _H)	7	6	5	4	3	2	1	0	
	XEN	0	0	IDLE					

(Initial value : 1000 ****)

XEN	High-frequency oscillator control	0 : Turn off oscillation 1 : Turn on oscillation	R/W
IDLE	IDLE mode start	0 : CPU, WDT operate 1 : CPU, WDT halt (IDLE mode start)	

Note 1 : An internal reset is applied if XEN is cleared to "0".

Note 2 : Always set bit 6, 5 to "0".

Note 3 : WDT ; Watchdog timer, * ; don't care

Note 4 : Bits 3 to 0 in SYSCR2 are read in as "1" when a read instruction is executed.

Figure 1-14. System Control Registers 1, 2

1.8.4 Operating Mode Control

(1) STOP mode (STOP)

STOP mode is controlled by the system control register 1 and the $\overline{\text{STOP}}$ pin input. The $\overline{\text{STOP}}$ pin is also used both as a port P43 and an $\overline{\text{INT5}}$ (external interrupt input 5) pin. The STOP mode is started by setting STOP (bit 7 in SYSCR1) to "1". During STOP mode, the following status is maintained.

- ① High-frequency oscillations are turned off, and all internal operations are halted.
- ② The data memory (except for DBR), registers, PSW, and port output latches are all held in the status in effect before STOP mode was entered. The port output can select either output hold or high-impedance by setting OUTEN (bit 4 in SYSCR1).
- ③ The divider of the timing generator is cleared to "0".
- ④ The program counter holds the address of the instruction after the following instruction which started the STOP mode. [for example, SET (SYSCR1)]

STOP mode includes a level sensitive release mode and an edge-sensitive release mode, either of which can be selected with RELM (bit 6 in SYSCR1).

a. Level-sensitive release mode (RELM = 1)

In this mode, $\overline{\text{STOP}}$ mode is released by setting the STOP pin high. This mode is used for capacitor back-up when the main power supply is cut off and long term battery back-up.

When the $\overline{\text{STOP}}$ pin input is high, executing an instruction which starts the STOP mode will not place in STOP mode but instead will immediately start the release sequence (WARM-up). Thus, to confirm that the $\overline{\text{STOP}}$ pin input is low. The following method can be used for confirmation:

Using an external interrupt input INT5 ($\overline{\text{INT5}}$ is a falling edge-sensitive input).

Example : Starting STOP mode with an INT5 interrupt.

PINT5 :	TEST	(P4) . 3	; To reject noise, the STOP mode does not start if
	JRS	F, SINT5	port P43 is at high.
	LD	(SYSCR1), 01000000B	; Sets up the level-sensitive release mode.
	SET	(SYSCR1) . 7	; Starts STOP mode
	LDW	(IL), 100001110101011B	; IL11, 5, 3 ← 0 (clears interrupt latches)
SINT5 :	RETI		

Figure 1-15. Level Mode

Note 1 : After warm-up start, even if $\overline{\text{STOP}}$ pin input is low again, STOP mode does not restart.

Note 2 : When changing to the level-sensitive release mode from the edge-sensitive release mode, the release mode is not switched until a rising edge of the $\overline{\text{STOP}}$ pin input is detected.

1.9.1 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to "0" by a reset or an instruction. Interrupt acceptance sequence requires 8 machine cycles after the completion of the current instruction execution. The interrupt service task terminates upon execution of an interrupt return instruction [RETI] (for maskable interrupts or [RETN](pseudo non-maskable interrupts). Figure 1-22 shows the timing chart of interrupt acceptance and interrupt return instruction.

(1) Interrupt acceptance processing

- ① The interrupt master enable flag (IMF) is cleared to "0" to temporarily disable the acceptance of any following maskable interrupts. When a non-maskable interrupt is accepted, the acceptance of any following interrupts is temporarily disabled.
- ② The interrupt latch (IL) for the interrupt source accepted is cleared to "0".
- ③ The contents of the program counter and the program status word are saved (pushed) onto the stack. (pushed down in order of PSW, PC_H, PC_L). The contents of Stack Pointer is decreased by 3.
- ④ The entry address of the interrupt service program is read from the vector table address corresponding to the interrupt source, and the entry address is loaded to the program counter.
- ⑤ The instruction stored at the entry address of the interrupt service program is executed.

Figure 1-22. Timing Chart of Interrupt Acceptance and Interrupt Return Instruction

Example : Correspondence between vector table address for INTTBT and the entry address of the interrupt service program.

A maskable interrupt is not accepted until the IMF is set to "1" even if a maskable interrupt of higher priority than that of the current interrupt interrupt being serviced. When nested interrupt service is necessary, the IMF is set to "1" in the interrupt service program. In this case, acceptable interrupt sources are selectively enabled by the individual interrupt enable flags. However, an acceptance of external interrupt 0 cannot be disabled by the EF, therefore, if disablement is necessary, either the external interrupt function must be disabled with the external interrupt control register (INT0EN) or interrupt processing must be avoided by the program. (When INT0EN = 0, the interrupt latch IL3 is not set, therefore, the falling edge of the INT0 pin input cannot be detected.)

When INT0EN = 0, the interrupt latch IL3 is not set, therefore, the falling edge of the $\overline{\text{INT0}}$ pin input cannot be detected.

Example 1 : Disables an external interrupt 0 using INT0EN:

```
CLR      (EINTCR).INT0EN ;INT0EN←0
```

Example 2 : Disables the processing of external interrupt 0 under the software control (using bit 0 at address 00F0H as the interrupt processing disable switch):

```
PINT0 :   TEST  (00F0H).0 ; Returns without interrupt processing if (00F0H)0 = 1.
          JRS   T, SINT0
          RETI
SINT0 :   Interrupt processing
          RETI
          ⋮
VINT0 :   DW     PINT0
```

(2) General-purpose register save / restore

During interrupt acceptance processing, the program counter and the program status word are automatically saved on the stack, but not the accumulator and other registers. These registers are saved by the program if necessary. Also, when nesting multiple interrupt services, it is necessary to avoid using the same data memory area for saving registers.

The following method is used to save / restore the general-purpose registers:

① General-purpose register save / restore by register bank changeover:

General-purpose registers can be saved at high-speed by switching to a register bank that is not in use. Normally, bank 0 is used for the main task and banks 1 to 15 are assigned to interrupt service tasks. To increase the efficiency of data memory utilization, the same bank is assigned for interrupt sources which are not nested.

The switched bank is automatically restored by executing an interrupt return instruction [RETI] or [RETN]. Therefore, it is not necessary for a program to save the RBS.

Example : Register Bank Changeover

```
PINTxx : LD     RBS, n ; Switches to bank n (1 μs at 8 MHz)
          Interrupt processing
          RETI ; Restores bank and Returns
```

- ② General-purpose register save / restore using push and pop instructions:
To save only a specific register, and when the same interrupt source occurs more than once, the general-purpose registers can be saved/restored using push/pop instructions.

Example : Register save using push and pop instructions

```

PINTxx : PUSH    WA          ; Save WA register pair
        PUSH    HL          ; Save HL register pair
        [Interrupt processing]
        POP     HL          ; Restore HL register pair
        POP     WA          ; Restore WA register pair
        RETI               ; Return
  
```

- ③ General-purpose registers save/restore using data transfer instruction:
Data transfer instructions can be used to save only a specific general-purpose register during processing of a single interrupt.

Example : Saving / Restoring registers by data memory transfer instructions

```

PINTxx : LD      (GSAVA), A   ; Save A register
        [Interrupt processing]
        LD      A, (GSAVA)   ; Restore A register
        RETI               ; Return
  
```

Figure 1-23. Saving / Restoring General-purpose Registers

(3) Interrupt return

The interrupt return instructions perform the following operations.

[RETI] Maskable interrupt return	[RETN] Non-maskable interrupt return
① The contents of the program counter and the program status word are restored from the stack. ② The stack pointer is incremented 3 times. ③ The interrupt master enable flag is set to "1".	① The contents of the program counter and program status word are restored from the stack. ② The stack pointer is incremented 3 times. ③ The interrupt master enable flag is set to "1" only when a non-maskable interrupt is accepted in interrupt enable status. However, the interrupt master enable flag remains at "0" when so clear by an interrupt service program.

Interrupt requests are sampled during the final cycle of the instruction being executed. Thus, the next interrupt can be accepted immediately after the interrupt return instruction is executed.

Note : When the interrupt processing time is longer than the interrupt request generation time, the interrupt service is performed but not the main task.

1.9.2 Software Interrupt (INTSW)

Executing the [SWI] instruction generates a software interrupt and immediately starts interrupt processing (INTSW is highest prioritized interrupt). However, if processing of a non-maskable interrupt is already underway, executing the SWI instruction will not generate a software interrupt but will result in the same operation as the [NOP] instruction.

Note : Software interrupt generates during non-maskable interrupt processing to use SWI instruction for software break in a development tool.

Use the [SWI] instruction only for detection of the address error or for debugging.

① Address Error Detection

FF_H is read if for some cause such as noise the CPU attempts to fetch an instruction from a non-existent memory address. Code FF_H is the SWI instruction, so a software interrupt is generated and an address error is detected. The address error detection range can be further expanded by writing FF_H to unused areas of the program memory. Address-trap-reset is generated for instruction fetch from RAM area (addresses 0040 to 013F_H) or SFR area (0000 to 003F_H).

Note : The fetch data from addresses, BF80 to BFFF_H for 87C409/809 and 87P809 is not "FF_H", because the outgoing test ROM is contained.

② Debugging

Debugging efficiency can be increased by placing the SWI instruction at the software break point setting address.

b. Edge mode (RELM = "0")

In this mode, STOP mode is released by a rising edge of the $\overline{\text{STOP}}$ pin input. This is used in applications where a relatively short program is repeatedly executed at periodic intervals. This periodic signal (for example, a clock from a low-power consumption oscillator) is input to the $\overline{\text{STOP}}$ pin.

In the edge-sensitive release mode, STOP mode is started even when the $\overline{\text{STOP}}$ pin input is high.

Example : Starting STOP mode operation in the edge-sensitive release mode

```
LD      (SYSCR1), 00000000B      ; OUTEN ← 0 (specifies high-impedance)
DI      ; IMF ← 0
SET     (SYSCR1). STOP          ; STOP ← 1 (activates STOP mode)
LDW     (IL), 100001110101011B  ; IL11, 5, 3 ← 0 (clears interrupt latches)
EI      ; IMF ← 1
```

Figure 1-16. Edge-sensitive Mode

STOP mode is released by the following sequence:

- ① The oscillator is turned on.
- ② A warming-up period is inserted to allow oscillation time to stabilize. During warm-up, all internal operations remain halted. Four different warming-up times can be selected with WUT (bits 3 and 2 in SYSCR1) as determined by the resonator characteristics.
- ③ When the warming-up time has elapsed, normal operation resumes with the instruction following the STOP mode start instruction. The start is made after the divider of the timing generator is cleared to "0".

Table 1-1. Warming-up Time example

Warming-up Time		
WUT	at $f_c = 4.194304$ MHz	at $f_c = 8$ MHz
00	375 ms	196.6 ms
01	125 ms	65.5 ms
10	2.93 ms	1.54 ms
11	976.6 μ s	512 μ s

Note : The warming-up time is obtained by dividing the basic clock by the divider: therefore, the warming-up time may include a certain amount of error if there is any fluctuation of the oscillation frequency when STOP mode is released. Thus, the warming-up time must be considered an approximate value.

STOP mode can also be released by setting the $\overline{\text{RESET}}$ pin low, which immediately performs the normal reset operation.

Figure 1-17. STOP Mode Start/Release

Note : When STOP mode is released with a low hold voltage, the following cautions must be observed.

The power supply voltage must be at the operating voltage level before releasing STOP mode. The RESET pin input must also be high, rising together with the power supply voltage. In this case, if an external time constant circuit has been connected, the RESET pin input voltage will increase at a slower rate than the power supply voltage. At this time, there is a danger that a reset may occur if input voltage level of the RESET pin drops below the non-inverting high-level input voltage (hysteresis input).

(2) IDLE mode (IDEL1)

IDLE mode is controlled by the system control register 2 (SYSCR2) and maskable interrupts. The following status is maintained during IDLE mode.

- ① Operation of the CPU and watchdog timer is halted. On-chip peripherals continue to operate.
- ② The data memory, CPU registers, PSW, and port output latches are all held in the status in effect before IDLE mode was entered.
- ③ The program counter holds the address of the instruction after the following instruction which started IDLE mode.

Example : Starting IDLE mode.

SET (SYSCR2).4

IDLE mode includes a normal release mode and an interrupt release mode. Selection is made with the interrupt master enable flag (IMF). Releasing the IDLE mode returns to NORMAL.

a. Normal release mode (IMF = "0")

IDLE mode is released by any interrupt source enabled by the individual interrupt enable flag (EF) or an external interrupt 0 (INT0) request. Execution resumes with the instruction following the IDLE mode start instruction. The interrupt latches (IL) of the interrupt source used for release is required to be cleared to "0" by load instruction.

b. Interrupt release mode (IMF = "1")

IDLE mode is released and interrupt processing is started by any interrupt source enabled with the individual interrupt enable flag (EF) or an external interrupt 0 (INT0) request. After the interrupt is processed, the execution resumes from the instruction following the instruction which started IDLE mode.

IDLE mode can also be released by setting the RESET pin low, which immediately performs the reset operation.

Note : When a watchdog timer interrupt is generated immediately before the IDLE mode is started, the watchdog timer interrupt will be processed by IDLE mode will not be started.

Figure 1-18. IDLE Mode

Figure 1-19. IDLE Mode Start/Release

1.9.3 External Interrupts

The 87C409/809 each have four external interrupt inputs. Two of these are equipped with digital noise rejection circuits(pulse inputs of less than a certain time are eliminated as noise).

Edge selection is also possible with INT1, INT3 pin. The $\overline{\text{INT0}}$ / P10 pin can be configured as either an external interrupt input pin or an input/output port, and is configured as an input port during reset.

Edge selection, noise rejection control and $\overline{\text{INT0}}$ / P10 pin function selection are performed by the external interrupt control register (EINTCR). Both edge detection of INT3 is controlled by the external interrupt 3 control register (INT3CR).

Table 1-3. External Interrupts

Source	Pin	Secondary function pin	Enable conditions	Edge			Digital noise rejection circuit
				rising	falling	both	
INT0	$\overline{\text{INT0}}$	P10	IMF = 1 INT0EN = 1	–	○	–	– (hysteresis input)
INT1	INT1	P11	IMF · EF ₅ = 1	INT1ES = 0	INT1ES = 1	–	Pulses of less than 15/fc or 63/fc[s] are eliminated as noise. Pulses equal to or more than 48/fc [s] or 192/fc [s] are regarded as signals.
INT3	INT3	P50 (TC3 / CLZ0)	IMF · EF ₁₁ = 1 INT3W = 0	INT3ES = 0	INT3ES = 1	–	For falling or rising edge, pulses less than 7/fc [s] are cancelled as noise. Pulses equal to or more than 24/fc [s] are regarded as signals.
			IMF · EF ₁₁ = 1 INT3W = 1	–	–	INT3W = 1	
INT5	$\overline{\text{INT5}}$	P43 / STOP	IMF · EF ₁₅ = 1	–	○	–	– (hysteresis input)

Note 1 : The noise rejection function is also affected to detect the edge of timer / counter input (TC1, TC3 pin).

Note 2 : The pulse width (both "H" and "L" level) for input to the $\overline{\text{INT0}}$ and $\overline{\text{INT5}}$ pins must be over 1 machine cycle.

Note 3 : If a noiseless signal is input to the external interrupt pin in the NORMAL or IDLE mode, the maximum time from the edge of input signal until the IL is set is as follows:

- ① INT1 pin 49/fc [s] (at INT1NC = 1), 193/fc [s] (at INT1NC = 0)
- ② INT3 pin 25/fc [s]

Note 4 : When INT0EN = 0, the interrupt latch IL3 is not set even if the falling edge of INT0 pin input is detected.

Note 5 : When high-impedance is specified for port output in STOP mode, port input is forcibly fixed to low level internally. Thus, interrupt latches of external interrupt inputs except P43 (STOP / INT5) which are also used as ports may be set to "1". To specify high-impedance for port output in STOP mode, first disable interrupt service (IMF = 0), activate stop mode. After releasing stop mode, clear interrupt latches using load instruction, then, enable interrupt service.

Example : Activating stop mode

```
LD    (SYSCR1), 01000000B    ; OUTEN←0 (specifies high-impedance)
DI                                ; IMF←0
SET   (SYSCR1), STOP        ; STOP←1 (activates STOP mode)
LDW   (IL), 1000011101010111B ; IL11, 5, 3←0 (clears interrupt latches)
EI                                ; IMF←1
```

Note 6 : When INT3W = 1, the edge of an interrupt can be detected by reading INT3R and INT3F (bits 6 and 5 in INT3CR).

EINTCR
(0037_H)

7	6	5	4	3	2	1	0
INT1 NC	INT0 EN			INT3 ES	TC1 ES	INT1 ES	

(Initial value : 00** 000*)

INT1NC	INT1 noise reject time select	0 : Pulses of less than 63/fc [s] are eliminated as noise 1 : Pulses of less than 15/fc [s] are eliminated as noise	R/W
INT0EN	P10 / $\overline{\text{INT0}}$ pin configuration	0 : P10 input / output port 1 : $\overline{\text{INT0}}$ pin (Port P10 should be set to an input mode.)	
INT3 ES TC1 ES INT1 ES	INT3, TC1, INT1 edge select	0 : Rising edge 1 : Falling edge	

Note : fc ; High-frequency clock [Hz] * ; don't care

INT3CR
(0025_H)

7	6	5	4	3	2	1	0
INT3W	INT3R	INT3F					

(Initial value : 000* ****)

INT3W	INT3 both edge selection	0 : Refer to INT3ES 1 : Both edge detection	Write Only
INT3R	INT3 rising edge detection flag	0 : Rising edge non-detected 1 : Rising edge detected	Read Only
INT3F	INT3 falling edge detection flag	0 : Falling edge non-detected 1 : Falling edge detected	

Note 1 : INT3R and INT3F are effective only in INT3W = 1.

Note 2 : INT3R and INT3F are cleared to "0" when reading the INT3CR.

Figure 1-24. External Interrupt Control Register

1.10 Watchdog Timer (WDT)

The watchdog timer rapidly detects the CPU malfunction such as endless looping caused by noise or the like, and resumes the CPU to the normal state.

The watchdog timer signal for detecting malfunction can be selected either an internal reset or a non-maskable interrupt request. However, selection is possible only once after reset.

After reset, the signal is initialised to the reset output.

When the watchdog timer is not being used for malfunction detection, it can be used as a timer to generate an interrupt at fixed intervals.

1.10.1 Watchdog Timer Configuration

Figure 1-25. Watchdog Timer Configuration

1.10.2 Watchdog Timer Control

Figure 1-26 shows the watchdog timer control registers. The watchdog timer is automatically enabled after reset.

(1) Malfunction detection methods using the watchdog timer

The CPU malfunction is detected as follows.

- ① Setting the detection time, selecting output, and clearing the binary counter.
- ② Repeatedly clearing the binary counter within the setting detection time.

If the CPU malfunction occurs for any cause, the watchdog timer output will become active at the rising of an overflow from the binary counters unless the binary counters are cleared. At this time, when WDTOUT = 1, an internal reset is generated. When WDTOUT = 0, a watchdog timer interrupt(INTWDT) is generated.

The watchdog timer temporarily stops counting in the STOP mode including warm-up or IDLE mode, and automatically restarts (continues counting) when the STOP / IDLE mode is released.

Example : Sets the watchdog timer detection time to $2^{21}/f_c[s]$ and resets the CPU malfunction.

	LD	(WDTCR2), 4EH	; Clears the binary counters
	LD	(WDTCR1), 00001101B	; WDTT←10, WDTOUT←1
Within 3/4 of WDT detection time	LD	(WDTCR2), 4EH	; Clears the binary counters (always clear immediately after changing WDTT)
	LD	(WDTCR2), 4EH	; Clears the binary counters
Within 3/4 of WDT detection time	LD	(WDTCR2), 4EH	; Clears the binary counters

Watchdog Timer Control Register 1								
WDTCR1 (0034 _H)	7	6	5	4	3	2	1 0	
					WDT EN	WDTT	WDT OUT	
(Initial value **** 1001)								
WDTEN	Watchdog timer enable / disable				0 : Disable (It is necessary to write the disable code to WDTCR2.) 1 : Enable			write only
WDTT	Watchdog timer detection time				00 : 2 ²⁵ / fc [s] 01 : 2 ²³ / fc 10 : 2 ²¹ / fc 11 : 2 ¹⁹ / fc			
WDTOUT	Watchdog timer output select				0 : Interrupt request 1 : Internal reset			
Note 1 : WDTOUT cannot be set to "1" by program after clearing WDTOUT to "0". Note 2 : fc ; High-frequency clock[Hz] * ; don't care Note 3 : WDTCR1 is a write-only register and must not be used with any of read-modify-write instructions. Note 4 : Disable the watchdog timer or clear the counter just before switching to STOP mode. When the counter is cleared just before switching to STOP mode, clear the counter again subsequently to releasing STOP mode. Note 5 : When WDTOUT = 1, internal reset time is 12/fc [s].								

Watchdog Timer Control Register 2								
WDTCR2 (0035 _H)	7	6	5	4	3	2	1 0	
(Initial value **** *)								
WDTCR2	Watchdog timer control code write register				4E _H : Watchdog timer binary counter clear (clear code) B1 _H : Watchdog timer disable (disable code) Others : Invalid			write only
Note 1 : The disable code is invalid unless written when WDTCR2 = 0. Note 2 : * ; don't care Note 3 : Since WDTCR2 is a write-only register, read-modify-write instructions (e.g., bit manipulating instructions such as SET or CLR and arithmetic instructions such as AND or OR) cannot be used for read / write to this register. Note 4 : To clear binary counter doesn't initialize the source clock, therefore, it is recommended to clear binary counter within 3/4 of the detection period.								

Figure 1-26. Watchdog Timer Control Registers

(2) Watchdog Timer Enable

The watchdog timer is enabled by setting WDTEN (bit 3 in WDTCR1). WDTEN is initialized to "1" during reset, so the watchdog timer operates immediately after reset is released.

(3) Watchdog Timer Disable

The watchdog timer is disabled by writing the disable code (B1_H) to WDTCR2 after clearing WDTEN (bit 3 in WDTCR1) to "0". The watchdog timer is not disabled if this procedure is reversed and the disable code is written to WDTCR2 before WDTEN is cleared to "0". During disabling the watchdog timer, the binary counters are cleared to "0".

Example: Disables watchdog timer

LDW (WDTCR1), 0B101H ; WDTEN←0, WDTCR2←disable code

Table 1-4. Watchdog Timer Detection Time

Detection time [s]	
WDTT	fc = 8 MHz
00	4.194
01	1.048
10	262.1 m
11	65.5 m

1.10.3 Watchdog Timer Interrupt (INTWDT)

This is a pseudo non-maskable interrupt which can be accepted regardless of the contents of the EIR. If a watchdog timer interrupt or a software interrupt is already accepted, however, the new watchdog timer interrupt waits until the previous interrupt processing is completed (the end of the [RETN] instruction execution).

The stack pointer (SP) should be initialized before using the watchdog timer output as an interrupt source with WDOUT.

Example: Watchdog timer interrupt setting up.

```
LD SP, 013FH          ; Sets the stack pointer
LD (WDTCR1), 00001000B ; WDOUT ← 0
```

1.10.4 Watchdog Timer Reset

If the watchdog timer output becomes active, an internal reset is generated, which reset the internal hardware. The internal reset time is $12/f_c$ [s] ($1.5 \mu\text{s}$ at 8 MHz). When an internal reset is generated, the $\overline{\text{RESET}}$ pin remains high.

Figure 1-27. Watchdog Timer Interrupt / Reset

1.11 Reset Circuit

TMP87C409/809 each have four types of reset generation procedures: an external reset input, an address trap reset, a watchdog timer reset and a system clock reset.

Figure 1-28 shows Reset Circuit, Table 1.5 shows on-chip hardware initialization by reset action.

Table 1-5. On-chip Hardware Initialization by Reset Action

On-chip Hardware	Initial Value	On-chip Hardware	Initial Value
Program counter (PC)	(FFFF _H) · (FFFE _H)	Prescaler and Divider of Timing generator	0
Register bank selector (RBS)	0	Watchdog timer	Enable
Jump status flag (JF)	1	Output latches of input/output port	Refer to I/O port circuitry
Interrupt master enable flag (IMF)	0	Control register	Refer to control registers
Interrupt individual enable flags (EF)	0		
Interrupt latches (IL)	0		

1.11.1 External Reset Input

The $\overline{\text{RESET}}$ pin contains a hysteresis input with an internal pull-up resistor. When the $\overline{\text{RESET}}$ pin is held at low for at least 3 machine cycles ($12/f_c$ [s]) with the power supply voltage within the operating voltage range and oscillation stable, a reset is applied and the internal state is initialized.

When the $\overline{\text{RESET}}$ pin input goes high, the reset operation is released and the program execution starts at the vector address stored at addresses FFFE to FFFF_H.

Figure 1-28. Reset Circuit

1.11.2 Address-Trap-Reset

An address-trap-reset is one of fail-safe function that detects CPU malfunction such as endless looping caused by noise or the like. If the CPU attempts to fetch an instruction from RAM or SFR, an internal reset will be generated. The reset time is $12/f_c$ ($1.5 \mu\text{s}$ at 8 MHz).

Figure 1-29. Address Trap Reset

1.11.3 Watchdog Timer Reset

Refer to Section "1.10 Watchdog Timer".

1.11.4 System Clock Reset

Clearing XEN to "0" stops a system clock, and causes CPU to deadlock. This can be prevented by automatically generating a reset signal whenever $\text{XEN} = 0$ is detected to continue the oscillation. Then internal reset is generated. The reset time is $12/f_c$ [s] ($1.5 \mu\text{s}$ at 8 MHz).

2. ON-CHIP PERIPHERALS FUNCTIONS

2.1 Special function register (SFR)

The TLCS-870 Series uses the memory mapped I/O system, and all peripheral control and data transfers are performed through the special function registers (SFR).

The SFR are mapped to addresses 0000 to 003F_H. Figure 2-1 shows the 87C409/809 SFR.

Address	Read	Write	Address	Read	Write
0000 _H		reserved	0020 _H	—	SBICR1 (SBI control 1)

(a) Special Function Register

Note 1 : Do not access reserved areas by the program.

Note 2 : — ; cannot be accessed.

Note 3 : When defining address 003F_H with assembler symbols, use GPSW and GRBS.

Note 4 : Write-only registers and interrupt latches cannot use the read-modify-write instructions (bit manipulation instructions such as SET, CLR, etc. and logical operation instructions such as AND, OR, etc.)

Note 5 : PSW ; Program Status Word

Figure 2-1. SFR

2.2 I/O Ports

The 87C409/809 have 4 ports, 22 pin input / output ports.

- ① P1 port ; 8-bit I/O port (external interrupt input, timer/counter input/output, and divider output)
- ② P4 port ; 4-bit I/O port (serial bus interface, external interrupt input)
- ③ P5 port ; 2-bit I/O port (timer/counter input/output, external interrupt input, oscillation stop detector output)
- ④ P6 port ; 8-bit I/O port (analog input, analog reference power supply)

Each output port contains a latch, which holds the output data. All input ports do not have latches, so the external input data should either be held externally until read or reading should be performed several times before processing. Figure 2-2 shows input / output timing examples.

External data is read from an I/O port in the S1 state of the read cycle during execution of the read instruction. This timing can not be recognized from outside, so that transient input such as chattering must be processed by the program. Output data output changes in the S2 state of the write cycle during execution of the instruction which writes to an I/O port.

Figure 2-2. Input / Output Timing (Example)

When reading an I/O port except programmable I/O ports, whether the pin input data or the output latch contents are read depends on the instructions, as shown below :

(1) Instructions that read the output latch contents

- ① XCH r, (src) ⑤ LD (pp).b, CF
- ② SET / CLR / CPL (src).b ⑥ ADD / ADDC / SUB / SUBB / AND / OR / XOR (src), n
- ③ SET / CLR / CPL (pp).g ⑦ (src) side of ADD / ADDC / SUB / SUBB / AND / OR / XOR (src), (HL)
- ④ LD (src).b, CF

(2) Instructions that read the pin input data

Instructions other than the above (1) and (HL) side of ADD / ADDC / SUB / SUBB / AND / OR / XOR (src), (HL)

2.2.1 Port P1 (P17 to P10)

Port P1 is an 8-bit input / output port which can be configured as an input or an output in on-bit unit. Input / output mode is specified by the port P1 input/output control register (P1CR). During reset, the P1CR is initialized to "0", which configures port P1 as an input. The P1 output latches are also initialized to "0".

Port P1 is also used as an external interrupt input, a timer / counter input, and a divider output. When used as secondary function pin, the input pins should be set to the input mode, and the output pins should be set to the output mode and beforehand the output latch should be set to "1". It is recommended that pins P11 and P12 should be used as external interrupt inputs, timer / counter input, or input ports. The interrupt latch is set at the rising or falling edge of the output when used as output ports. Pin 10 can be configured as either an input / output ports with INTOEN or an external interrupt input. During reset, pin P10 is configured as an input port.

Figure 2-3. Port 1 and P1CR

Example : Sets P17, P16 and P14 as output ports, P13 and P11 as input ports, and the others as function pins. Internal output data is "1" for the P17 and P14 pins, and "0" for the P16 pin.

```
LD  (EINTCR), 01000000B      ; INTOEN←1
LD  (P1), 10111111B          ; P17←1, P14←1, P16←0
LD  (P1CR), 11010000B
```

Note 1 : Ports set to the input mode read the pin states. When input pin and output pin exist in port P1 together, the contents of the output latch of ports set to the input mode may be rewritten by executing the bit manipulation instructions. Pins set to the output mode read a value of the output latch.

Note 2 : The P1CR is a write-only register. It can not be operated by the read-modify instruction (Bit manipulation instructions of SET, CLR, etc. and Arithmetic instructions of AND, OR, etc.)

2.2.3 Port P5 (P51 to P50)

Port P5 is a 2-bit general-purpose input/output port which can be configured as an input or an output in one-bit unit. High current output is available so LEDs can be driven directly.

Input/output mode is specified by the port P5 input/output control register (P5CR). During reset, the P5CR is initialized to "0", which configures port P5 as an input. The P5 output latches are also initialized to "0".

Port P5 is also used as a timer/counter input, an external interrupt input and a oscillation stop detector output. When used as secondary function pin, the input pins should be set to the input mode, and the output pins should be set to the output mode. When used as timer/counter input, the output latch should be set to "1".

Figure 2-5. Port P5 and P5CR

Note 1 : Ports set to the input mode read the pin states. When input pin and output pin exist in port P5 together, the contents of the output latch of ports set to the input mode may be rewritten by executing the bit manipulation instructions. Pins set to the output mode read a value of the output latch.

Note 2 : The P5CR is a write-only register. It can not be operated by the read-modify instruction (Bit manipulation instructions of SET, CLR, etc. and Arithmetic instructions of AND, OR, etc.)

2.2.4 Port P6 (P67 to P60)

Port P6 is an 8-bit general-purpose input/output port which can be configured as an input or an output in one-bit unit. Port P6 is also used as analog inputs and P67 can be configured as an analog reference power supply pin (VAREF) by setting SREF to "1" (bit 7 in SELREF). Input / output mode is specified by port P6 input/output control register (P6CR) and AINDS (bit 4 in ADCCR). During reset, P6CR is set to "0", AINDS is set to "1", and port P6 is in input mode. During reset, the output latches of port P6 is initialized to "0". P6CR is write-only register. When port P6 is not used as analog input, it can be used input / output port. However output instructions must not be performed to maintain the precision at using A/D converter. When the input instruction is executed to port P6 during using A/D converter, "0" is read into the pin that selects analog input, and "1" or "0" is read into the pin that does not select analog input, depending on the input level of pins.

Figure 2-6. Port P6, P6CR and SELREF

Note 1 : Ports set to the input mode read the pin states. When input pin and output pin exist in port P6 together, the contents of the output latch of ports set to the input mode may be rewritten by executing the bit manipulation instructions. Pins set to the output mode read a value of the output latch.

Note 2 : The P6CR and SELREF are a write-only registers. They can not be operated by the read-modify instruction (Bit manipulation instructions of SET, CLR, etc. and Arithmetic instructions of AND, OR, etc.)

Example : The lower 4-bit of Port P6 is set to an output port and the others are set to an input port.

LD (P6CR), 0FH ; P6CR←00001111

2.3 Time Base Timer (TBT)

The time-base timer is used to generate the base time for key scan and dynamic display processing. For this purpose, it generates a time-base timer interrupt (INTTBT) at predetermined intervals.

This interrupt is generated beginning with the first rising edge of the source clock (the timing generator's divider output selected by TBTCK) after the time-base timer is enabled. Note that since the divider cannot be cleared by a program, the first interrupt only may occur earlier than the set interrupt period. (See Figure 2-7. (b).)

When selecting the interrupt frequency, make sure the time-base timer is disabled. (Do not change the selected interrupt frequency when disabling the active timer either.) However, you can select the interrupt frequency simultaneously when enabling the timer.

Figure 2-7. Time Base Timer

7 6 5 4 3 2 1 0								
(DVOEN)		(DVQCK)		0	TBTEN	TBTCK		
(Initial value : 0**0 0***)

110	3906.25
111	15625

2.4 Divider Output ($\overline{\text{DVO}}$)

A 50% duty pulse can be output using the divider output circuit, which is useful for piezo-electric buzzer drive. Divider output is from pin P13 ($\overline{\text{DVO}}$). The P13 output latch should be set to "1" and then the P13 should be configured as an output mode.

TBTCR (0036 _H)	7	6	5	4	3	2	1	0	(Initial value : 0**0 0***)
	DVOEN	DVOCK	0	(TBTEN)		(TBTKC)

01	1.024	1.953
10	2.048	3.906
11	4.096	7.812

Figure 2-10. Divider Output

2.5.3 Function

Timer/counter 1 has two operating modes: timer mode and event counter mode.

(1) Timer Mode

In this mode, counting up is performed using the internal clock. The contents of TREG1 are compared with the contents of up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared to "0". Counting up resumes after the counter is cleared.

Table 2-3. Timer/Counter 1 Source Clock (Internal Clock)

Source clock	Resolution	Maximum time setting
NORMAL, IDLE modes	At $f_c = 8 \text{ MHz}$	At $f_c = 8 \text{ MHz}$
$f_c / 2^3 [\text{Hz}]$	$1 \mu\text{s}$	65.5 ms
$f_c / 2^7$	$16 \mu\text{s}$	1.0 s
$f_c / 2^{11}$	$256 \mu\text{s}$	16.7 s

Example : Sets the timer mode with source clock $f_c/2^{11}[\text{Hz}]$ and generates an interrupt 1 s. later (at $f_c = 8 \text{ MHz}$).

```
LD      (TC1CR), 00000000B      ; Sets the TC1 mode and source clock
LDW     (TREG1), 0F42H          ; Sets the timer register ( $1 \text{ s} \div 2^{11} / f_c = \text{F42H}$ )
LD      (TC1CR), 00010000B      ; Starts TC1
```

Figure 2-13. Timer Mode Timing Chart

(2) Event Counter Mode

In this mode, events are counted on the edge of the TC1 pin input. Either the rising or falling edge can be selected with TC1ES in EINTCR. The contents of TREG1 are compared with the contents of the up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared. The maximum applied frequency is $f_c/24 [\text{Hz}]$ in NORMAL or IDLE mode.

Figure 2-14. Event Counter Mode Timing Chart (TC1ES = 1)

2.6 8-Bit Timer/Counter 3 (TC3)

2.6.1 Configuration

Figure 2-15. Timer/Counter 3

2.6.2 Control

TREG3A (0018 _H)	7	6	5	4	3	2	1	0	Read/Write
TREG3B (0019 _H)	7	6	5	4	3	2	1	0	Read only
TC3CR (001A _H)	7	6	5	4	3	2	1	0	(Initial value : *0*0 00*0)
TC3M	Timer/counter 3 operation mode set							0 : Timer/event counter 1 : Capture	Write only
TC3CK	Timer/counter 3 source clock select							00 : Internal clock $f_c / 2^{12}$ [Hz] 01 : Internal clock $f_c / 2^{10}$ 10 : Internal clock $f_c / 2^7$ 11 : External clock (TC3 pin input)	
TC3S	Timer/counter 3 start select							0 : Stop & clear 1 : Start	
SCAP	Software capture control							0 : — 1 : Software capture	

Note 1 : f_c ; High-frequency clock [Hz] * ; don't care
 Note 2 : Set the mode, the source clock and the edge selection (INT3ES) when the TC3 stops (TC3S = 0).
 Note 3 : Values to be loaded into timer register 3A must satisfy the following condition.
 $TREG3A > 0$ (in the timer/event counter mode)
 Note 4 : TC3CR is a write-only register and must not be used with any of read-modify-write instructions.

Figure 2-16. Timer Register 3A/3B and TC3 Control Register

The timer/counter 3 is controlled by a timer/counter 3 control register (TC3CR) and two 8-bit timer registers (TREG3A and TREG3B). Reset does not affect these timer registers.

2.6.3 Function

The timer/counter 3 has three operating modes : timer, event counter, and capture mode.

(1) Timer Mode

In this mode, the internal clock is used for counting up. The contents of TREG3A are compared with the contents of up-counter. If a match is found, a timer/counter 3 interrupt (INTTC3) is generated, and the up-counter is cleared. Counting up resumes after the up-counter is cleared. The current contents of up-counter are loaded into TREG3B by setting SCAP (bit 6 in TC3CR) to "1". SCAP is automatically cleared after capturing.

Table 2-4. Source Clock (Internal Clock) for Timer Counter 3

Source clock	Resolution	Maximum setting time
NORMAL, IDLE mode	$f_c = 8 \text{ MHz}$	$f_c = 8 \text{ MHz}$
$f_c / 2^{12} \text{ [Hz]}$	$512 \mu\text{s}$	131.1 ms
$f_c / 2^{10}$	$128 \mu\text{s}$	32.6 ms
$f_c / 2^7$	$16 \mu\text{s}$	4.1 ms

(2) Event Counter Mode

In this mode, the TC3 pin input pulses are used for counting up. Either the rising or falling edge can be selected with INT3ES (bit 3 in EINTCR). Both edges can not be used. The contents of TREG3A are compared with the contents of the up-counter. If a match is found, an INTTC3 interrupt is generated and the counter is cleared. The maximum applied frequency is $f_c/2^4 \text{ [Hz]}$ in the NORMAL or IDLE mode. Two or more machine cycles are required for both the "H" and "L" levels of the pulse width. The current contents of up-counter are loaded into TREG3B by setting SCAP (bit 6 in TC3CR) to "1". SCAP is automatically cleared after capturing.

Example : Generates an interrupt every 0.5 s, inputting 50Hz pulses to the TC3 pin.

```
LD (TC3CR), 00001100 ; Sets TC3 mode, source clock
LD (TREG3A), 19H      ;  $0.5 \text{ s} \div 1/50 = 25 = 19_{\text{H}}$ 
LD (TC3CR), 00011100B ; Start TC3
```

(3) Capture Mode

The pulse width, period and duty of the TC3 pin input are measured in this mode, which can be used in decoding the remote control signals, etc. The counter is free running by the internal clock. On the rising (falling) edge of the TC3 pin input, the current contents of counter is loaded into TREG3A, then the up-counter is cleared and an INTTC3 interrupt is generated. On the falling (rising) edge of the TC3 pin input, the current contents of the counter is loaded into the TREG3B. In this case, counting continues. At the next rising (falling) edge of the TC3 pin input, the current contents of counter are loaded into TREG3A, then the counter is cleared again and an interrupt is generated. If the counter overflows before the edge is detected, FF_{H} is set to the TREG3A and an overflow interrupt (INTTC3) is generated. During interrupt processing, it can be determined whether or not there is an overflow by checking whether or not the TREG3A value is FF_{H} . Also, after an interrupt (capture to TREG3A, or overflow detection) is generated, capture and overflow detection are halted until TREG3A has been read out; however, the counter continues.

Figure 2-17. Timing Chart for Capture Mode (INT3ES = 0)

2.7.2 Control

The timer/counter 4 is controlled by a timer/counter 4 control register (TC4CR) and an 8-bit timer register 4 (TREG4). Reset does not affect TREG4.

TREG4
(001B_H)

7	6	5	4	3	2	1	0

TC4CR
(001C_H)

7	6	5	4	3	2	1	0
TFF4		"0"	TC4S	TC4CK	TC4M		

Write only

(Initial value : 00*0 0000)

TC4M	TC4 operating mode select	00 : Timer mode 01 : Reserved 10 : Programmable divider output (PDO) mode 11 : Pulse width modulation (PWM) output mode	Write only
TC4CK	TC4 source clock select	00 : Internal clock $f_c / 2^{11}$ [Hz] 01 : Internal clock $f_c / 2^7$ 10 : Internal clock $f_c / 2^3$ 11 : External clock (TC4 pin input)	
TC4S	TC4 start control	0 : Stop & clear 1 : Start	
TFF4	Timer F/F 4 control	00 : Clear 01 : Toggle 10 : Set 11 : – (Note 3)	

Note 1 : f_c ; High-frequency clock [Hz], *; don't care

Note 2 : Set the operating mode, the source clock selection, the timer F/F 4 control and the edge selection (INT4ES) when the TC4 stops (TC4S = 0).

Note 3 : TFF4 must be set to "11" in the timer and event counter modes.

Note 4 : Values to be loaded to the timer register must satisfy the following condition.

$TREG4 > 0$

Note 5 : TC4CR and TREG4 are write-only registers and must not be used with any of read-modify-write instructions.

Figure 2-19. Timer Register 4 and TC4 Control Register

2.7.3 Function

The timer/counter 4 has four operating modes : timer, event counter, programmable divider output, and PWM output mode.

(1) Timer Mode

In this mode, the internal clock is used for counting up. The contents of TREG4 are compared with the contents of up-counter. If a match is found, a timer/counter 4 interrupt (INTTC4) is generated and the up-counter is cleared to "0". Counting up resumes after the up-counter is cleared.

Table 2-5. Source Clock (Internal Clock) for Timer/Counter 4

Source clock	Resolution	Maximum setting time
NORMAL, IDLE mode	$f_c = 8 \text{ MHz}$	$f_c = 8 \text{ MHz}$
$f_c / 2^{11}$ [Hz]	$256 \mu\text{s}$	65.3 ms
$f_c / 2^7$	$16 \mu\text{s}$	4.1 ms
$f_c / 2^3$	$1 \mu\text{s}$	$255 \mu\text{s}$

(2) Programmable Divider Output (PDO) Mode

The internal clock is used for counting up. The contents of TREG4 are compared with the contents of the up-counter. Timer F/F 4 output is toggled and the counter is cleared each time a match is found. Timer F/F 4 output is inverted and output to the $\overline{\text{PDO}}$ (P51) pin. This mode can be used for 50 % duty pulse output. Timer F/F 4 can be initialized by program, and it is initialized to "0" during reset. An INTTC4 interrupt is generated each time the $\overline{\text{PDO}}$ output is toggled.

Example : Output a 1024 Hz pulse (at $f_c = 4.194304$ MHz)

```
SET      (P5). 1           ; P51 output latch ← 1
LD       (P5CR), 00000010  ; Sets P51 (output mode)
LD       (TREG4), 10H      ; (1/1024 ÷ 27/fc) ÷ 2 = 10H
LD       (TC4CR), 00010010B ; Starts TC4
```

Figure 2-20. Timing Chart for PDO Mode

(3) Pulse Width Modulation (PWM) Output Mode

PWM output with a resolution of 8 bits is possible. The internal clock is used for counting up. The contents of TREG4 are compared with the contents of up-counter. If a match is found, the timer F/F 4 output is toggled. The counter continues counting. And, when an overflow occurs, the timer F/F 4 output is again toggled and the counter is cleared. Timer F/F 4 output is inverted and output to the $\overline{\text{PWM}}$ (P51) pin. An INTTC4 interrupt is generated when an overflow occurs.

TREG4 is configured a 2-stage shift register and, during output, will not switch until one output cycle is completed even if TREG4 is overwritten; therefore, output can be altered continuously. Also, the first time, TREG4 is shifted by setting TC4S (bit 4 in TC4CR) to "1" after data are loaded to TREG4.

Note : Do not overwrite TREG4 only when an INTTC4 interrupt is generated. Usually, TREG4 is overwritten in the routine of INTTC4 interrupt service.

Figure 2-21. Timing Chart for PWM Mode

Table 2-6. PWM Output Mode

Source clock	Resolution	Maximum setting time
NORMAL, IDLE mode	$f_c = 8 \text{ MHz}$	$f_c = 8 \text{ MHz}$
$f_s / 2^{11} \text{ [Hz]}$	$256 \text{ } \mu\text{s}$	65.5 ms
$f_c / 2^7$	$16 \text{ } \mu\text{s}$	4.1 ms
$f_c / 2^3$	$1 \text{ } \mu\text{s}$	$256 \text{ } \mu\text{s}$

2.8 Serial Bus Interface (SBI-ver. B)

The 87C409/809 each have a 1-channel serial bus interface which employs a clocked-synchronous 8-bit serial bus interface and an I²C bus. (a bus system by philips)

The serial bus interface is connected to an external device through P42 (SDA) and P41 (SCL) in the I²C bus mode; and through P40 (SCK), P42 (SO), and P41 (SI) in the clocked-synchronous 8-bit SIO mode.

The serial bus interface pins are also used as the P4 port. When used for serial bus interface pins, set the P4 output latches of these pins to "1". When not used as serial bus interface pins, the P4 port is used as a normal I/O port.

2.8.1 Configuration

Figure 2-22. Serial Bus Interface (SBI-ver. B)

2.8.2 Serial Bus Interface (SBI-ver. B) Control

The following registers are used for control and operation status monitoring when using the serial bus interface (SBI-ver. B).

- Serial bus interface control register 1 (SBICR1)
- Serial bus interface control register 2 (SBICR2)
- Serial bus interface data buffer register (SBIDBR)
- I²C bus address register (I2CAR)
- Serial bus interface status register (SBISR)

The above registers differ depending on a mode to be used.

Refer to Section "2.8.4 I²C bus Mode Control" and "2.8.6 Clocked-synchronous 8-bit SIO Mode Control".

2.8.3 The Data Formats in the I²C bus Mode

The data formats in the I²C bus mode are shown below.

(a) Addressing format

(b) Addressing format (with restart)

(c) Free data format

Note : S : Start condition
 R/W : Direction bit
 ACK : Acknowledge bit
 P : Stop condition

Figure 2-23. Data Format at I²C bus mode

2.8.4 I²C Bus Mode Control

The following registers are used for control the serial bus interface (SBI-ver. B) and monitor the operation status in the I²C bus mode.

Serial Bus Interface Control Register 1									
SBICR1 (0020 _H)		7	6	5	4	3	2	1	0
		BC		ACK		SWRST		SCK	
(Initial value 0000 *000)									
BC	Number of transferred bits	BC	ACK = 0			ACK = 1			Write only
			Number of Clock	Bits	Number of Clock	Bits			
		000	8	8	9	8			
		001	1	1	2	1			
		010	2	2	3	2			
		011	3	3	4	3			
		100	4	4	5	4			
		101	5	5	6	5			
110	6	6	7	6					
111	7	7	8	7					
ACK	Acknowledge mode specification	0 : Not generate clock pulse for acknowledge signal (in master mode) / Not count clock pulse for acknowledge signal (in slave mode) 1 : Generate clock pulse for acknowledge signal (in master mode) / Count clock pulse for acknowledge signal (in slave mode)							Read/Write
SWRST	Initiate a internal of SBI	0 : – 1 : Initialized (Clearing “0” after initialized)							Read/Write
SCK	Serial clock selection	000 : 200.0 kHz 001 : 111.1 kHz 010 : 58.8 kHz 011 : 30.3 kHz 100 : 15.4 kHz 101 : 7.75 kHz 110 : 3.89 kHz 111 : reserved } at fc = 8 MHz (Output on SCL pin)							Write only

Note 1 : fc ; high-frequency clock [Hz], * ; don't care

Note 2 : Set the BC to “000” before switching to a clock-synchronous 8-bit SIO bus mode.

Note 3 : SBICR1 has write-only register bits, which cannot access any of in read-modify-write instructions such as bit operate, etc.

Note 4 : * ; don't care

Serial Bus Interface Data Buffer Register									
SBIDBR (0021 _H)		7	6	5	4	3	2	1	0
		Read / Write (Initial value 0000 0000)							
Note 1 : When writing transmitted data, start from the MSB (bit7). Note 2 : Cannot read the data which was written into SBIDBR, since a write data buffer and a read data buffer are independent in SBIDBR. Therefore, cannot access it any of in read-modify-write instructions such as bit operate, etc. Note 3 : The data which was written into SBIDBR is cleared to “0” when INTSBI is generated.									

I ² C bus Address Register									
I2CAR (0022 _H)		7	6	5	4	3	2	1	0
		Slave address							ALS
		SA6	SA5	SA4	SA3	SA2	SA1	SA0	
(Initial value 0000 0000)									
SA	87C409/809 slave address selection								
ALS	Address recognition mode specification							0 : Slave address recognition 1 : Non slave address recognition	
Write only									

Note : I2CAR is a write-only register, which cannot access any of in read-modify-write instructions such as bit operate, etc.

Figure 2-24. Serial Bus Interface Control Register 1/Serial Bus Interface Data Buffer Register/
I²C bus Address Register in the I²C bus Mode

Serial Bus Interface Control Register 2

SBICR2
(0023_H)

7	6	5	4	3	2	1	0	
MST	TRX	BB	PIN	SBIM		"0"	"0"	(Initial value 0001 00**)

MST	Master/slave selection	0 : Slave 1 : Master	Write only
TRX	Transmitter/receiver selection	0 : Receiver 1 : Transmitter	
BB	Start/stop generation	0 : Generate the stop condition when the MST, TRX, and PIN are "1". 1 : Generate the start condition when the MST, TRX, and PIN are "1".	
PIN	Cancel interrupt service request	0 : – (cannot be cleared to "0") 1 : Cancel interrupt service request	
SBIM	Serial bus interface operating mode selection	00 : Port mode (serial bus interface output disable) 01 : SIO mode 10 : I ² C bus mode 11 : Reserved	

Note 1 : * ; don't care

Note 2 : Switch a mode to port mode after confirming that the bus is free.

Note 3 : Switch a mode to I2Cbus mode after confirming that input signals via port are high level.

Note 4 : SBICR2 has write-only register bits, which cannot access any of in read-modify-write instructions such as bit operate, etc.

Note 5 : Write "0" to bit 1, 0 in the SBICR2.

Serial Bus Interface Status Register

SBISR
(0023_H)

7	6	5	4	3	2	1	0	
MST	TRX	BB	PIN	AL	AAS	AD0	LRB	(Initial value 0001 0000)

BB	I ² C bus status monitor	0 : Bus free 1 : Bus busy	
PIN	Interrupt service request status monitor	0 : INTSBI occurs 1 : INTSBI does not occur	
AL	Arbitration loss detection monitor	0 : Arbitration loss undetected 1 : Arbitration loss detected	
AAS	Slave address match detection monitor	0 : Slave address unmatched or "GENERAL CALL" undetected 1 : Slave address match or "GENERAL CALL" detected	
AD0	"GENERAL CALL" detection monitor	0 : "GENERAL CALL" undetected 1 : "GENERAL CALL" detected	
LRB	Last received bit monitor	0 : Last received bit "0" 1 : Last received bit "1"	

Figure 2-25. Serial Bus interface Control Register 2/Serial Bus interface status register in the I²Cbus Mode

(1) Acknowledge mode specification

Set the ACK (bit 4 in SBICR1) to "1" for operation in the acknowledge mode. The 87C409/809 generate an additional clock pulse for an acknowledge signal when operating in the master mode. In the transmitter mode during the clock pulse cycle, the SDA pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during the clock pulse cycle, the SDA pin is set to the low level in order to generate the acknowledge signal.

Reset the ACK for operation in the non-acknowledge mode. The 87C409/809 don't generate a clock pulse for the acknowledge signal when operating in the master mode.

In the acknowledge mode, the 87C409/809 count a clock pulse for the acknowledge signal when operating in the slave mode. During the clock pulse, when the received slave address is the same as the value set at the I2CAR or when a GENERAL CALL is received, the SDA pin is set to the low level in order to generate the acknowledge signal.

In the transmitter mode during the clock pulse cycle after matching the slave addresses or receiving a GENERAL CALL, the SDA pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during the clock pulse cycle, the SDA pin is set to the low level in order to generate the acknowledge signal.

In non-acknowledge mode, the 87C409/809 don't count a clock pulse for the acknowledge signal when operating in the slave mode.

(2) Number of transfer bits

The BC (bits 7 to 5 in the SBICR1) is used to select a number of bits for next transmitting and receiving data.

Since the BC is cleared to "000" as a start condition, a slave address and direction bit transmissions are executed in 8 bits. Other than these, the BC retains a specified value.

(3) Serial clock**a. Clock source**

The SCK (bits 2 to 0 in the SBICR1) is used to select a maximum transfer frequency outputted on the SCL pin in the master mode.

In both master mode and slave mode, a pulse width of at least 4 machine cycles is require for both high and low levels.

Figure 2-26. Clock Source

b. Clock synchronization

In the I²C bus mode, in order to drive a bus with a wired-AND, a master device which pulls down a clock line to low-level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

The 87C409/809 have a clock synchronization function for normal data transfer even when more than one master exists on a bus.

The example explains clock synchronization procedures when two masters simultaneously exist on a bus.

Figure 2-27. Clock Synchronization

As Master 1 pulls down the SCL pin to the low level at point "a", the SCL line of the bus becomes the low-level. After detecting this situation, Master 2 resets counting a clock pulse in the high level and sets the SCL pin to the low-level.

Master 1 finishes counting a clock pulse in the low level at point "b" and sets the SCL pin to the high level. Since Master 2 holds the SCL line of the bus at the low-level, Master 1 waits for counting a clock pulse in the high level. After Master 2 sets a clock pulse to the high level at point "c" and detects the SCL line of the bus at the high-level, Master 1 starts counting a clock pulse in the high level.

The clock pulse on the bus is determined by the master device with the shortest high-level period and the master device with the longest low-level period from among those master devices connected to the bus.

(4) Slave address and Address recognition mode specification

When the serial bus interface circuit is used with an addressing format to recognize the slave address, clear the ALS (bit 0 in I2CAR) to "0", and set the SA (bits 7 to 1 in I2CAR) to the slave address. When the serial bus interface circuit is used with a free data format not to recognize the slave address, set the ALS to "1". With a free data format, the slave address and the direction bit are not recognized, and they are processed as data from immediately after start condition.

(5) Master/slave selection

Set the MST (bit 7 in the SBICR2) to "1" for operating the 87C409/809 as a masterdevice. Reset the MST to "0" for operation as a slave device. The MST is cleared to "0" by the hardware after a stop condition on a bus is detected or arbitration lost is detected.

(6) Transmitter / receiver selection

Set the TRX (bit 6 in SBICR2) to "1" for operating the 87C409/809 as a transmitter. Reset the TRX for operation as a receiver. When data with an addressing format is transferred in the slave mode, the TRX is set to "1" if the direction bit ($R/\bar{W}$) sent from the master device is "1", and is cleared to "0" if the bit is "0". In the master mode, after an acknowledge signal is returned from the slave device with the hardware, the TRX is set to "0" if a transmitted direction bit is "1", and set to "1" if it is "0". When an acknowledge signal is not returned, the current condition is maintained.

The TRX is cleared to "0" by the hardware after a stop condition on the bus is detected or arbitration is lost.

The following table shows TRX changing conditions and TRX value after changing.

Mode	Direction bit	Conditions	TRX after changing
Slave mode	0	When the received slave address is the same as I2CAR	0
	1		1
Master mode	0	When the ACK signal is returned	1
	1		0

When the serial bus interface circuit is used with a free data format, the TRX is not changed by hardware since the slave address and the direction bit are not recognized, and they are processed as data from immediately after start condition.

(7) Start / stop condition generation

A start condition and 8-bit data are output on the bus by writing "1" to the MST, TRX and BB when the BB (bit 5 in SBICR2) is "0". It is necessary to set the transmitting data to the data buffer register and "1" to ACK beforehand.

Figure 2-28. Start Condition Generation and Slave Address Generation

When the BB is "1", a sequence of generating a stop condition is started by writing "1" to the MST, TRX, and PIN, and "0" to the BB.

Do not modify the contents of MST, TRX, BB and PIN until a stop condition is generated on a bus.

Note : When a stop condition is generated and bus SCL line is set to Low level by the other devices, a stop condition is not started normally. Write "1" to the MST, TRX, and PIN, and "0" to the BB to generate a stop condition after releasing the SLC line.

Figure 2-29. Stop Condition Generation

Note : When a stop condition is generated, a time to rise the SCL line should not exceed $tr = 2^n / fc - 3.5 \times 4 / fc$ (s). (n depends on the SCK) If the rising time of the SCL line exceeds the above value, there is a probability that a stop condition is not started normally.

SCK	n	tr (Max., fc = 8 MHz)	tr (Max., fc = 4 MHz)
000	4	0.25 us	0.50 us
001	5	2.25 us	4.50 us
010	6	6.25 us	12.5 us
011	7	14.2 us	28.5 us
100	8	30.2 us	60.5 us
101	9	62.5 us	124.5 us
110	10	126.25 us	252.5 us

fc ; High frequency [Hz]

The bus condition can be indicated by reading the contents of the BB (bit 5 in the SBISR). The BB is set to "1" when a start condition on a bus is detected, and is cleared to "0" when a stop condition is detected on a bus.

(8) Interrupt service request cancel

In the master mode, a serial bus interface interrupt request (INTSBI) occurs after the number of clocks which is specified by the BC and ACK has been transmitted.

In the slave mode, when the received slave address is the same as the value set at the I2CAR, after outputting the acknowledge signal when a GENERAL CALL is received, or when data transfer is complete after matching the slave addresses or receiving a GENERAL CALL, an INTSBI interrupt request occurs.

When a serial bus interface interrupt request occurs, the PIN (bit 4 in SBISR) is cleared to "0". During the time that the PIN is "0", the SCL pin is pulled down to the low level.

Either writing / reading data to / from the SBIDBR sets the PIN to "1".

The time from the PIN being set to "1" until the SCL pin is released takes t_{LOW} .

Although the PIN (bit 4 in SBICR2) can be set to "1" by the program, the PIN is not set to "0" when "0" is written.

(9) Serial bus interface operating mode

The SBIM (bits 3, 2 in SBICR2) is used to specify the serial bus interface operation mode. Set the SBIM to "10" after confirming that the serial bus interface pin is set to high level when used in the I2C bus mode.

Switch a mode to port after making sure that a bus is free.

(10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on a bus in the I2C bus mode, a bus arbitration procedure is implemented in order to guarantee the contents of transferred data.

Data on the SDA line is used for bus arbitration of the I2C bus.

The following shows an example of a bus arbitration procedure when two master devices exist simultaneously on the bus. Master 1 and Master 2 output the same data until point "a". After Master 1 outputs "1" and Master 2, "0", the SDA line of the bus is wired AND and the SDA line is pulled down to the low level by Master 2. When the SCL line of the bus is pulled up at point "b", the slave device reads data on the SDA line, that is, data in Master 2. Data transmitted from Master 1 becomes invalid. The state in Master 1 is called "arbitration lost". A master device which loses arbitration releases the SDA pin and the SCL pin in order not to effect data transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

Figure 2-30. Arbitration Lost

The 87C409/809 compare levels of the SDA line of the bus with those of the 87C409/809 SDA pin at the rising edge of the SCL line. If the levels are unmatched, arbitration is lost and the AL (bit 3 in SBISR) is set to "1".

When the AL is set to "1", the MST and TRX are reset to "0" and the mode is switched to a slave receiver mode.

The AL is reset to "0" by writing/reading data to / from the SBIDBR or writing data to the SBICR2.

Figure 2-31. Example of Arbitration Lost of when 87C409/809 are a Master Device B

(11) Slave address match detection monitor

The AAS (bit 2 in the SBISR) is set to "1" in the slave mode, in the address recognition mode (ALS = 0), when receiving GENERAL CALL or a slave address with the same value that is set to the I2CAR. When the ALS is "1", the AAS is set to "1" after receiving the first 1-word of data. The AAS is cleared to "0" by after writing/reading data to/from a data buffer register.

(12) GENERAL CALL detection monitor

The AD0 (bit 1 in SBISR) is set to "1" in the slave mode, when all 8-bit data received immediately after a start condition are "0". The AD0 is cleared to "0" when a start or stop condition is detected on the bus.

(13) Last received bit monitor

The SDA value stored at the rising edge of the SCL line is set to the LRB (bit 0 in SBISR). When the contents of the LRB are read immediately after an INTSBI interrupt request is generated in the acknowledge mode, and ACK signal is read.

(14) Software reset function

Software reset function is used to initialize SBI, when SBI is locked by external noise, etc. SWRST is set to "1", internal reset signal pulse is generated and inputted into SBI circuit. All command registers and status registers are initialized to an initial value. SWRST is automatically cleared to "0" after initialize SBI circuit.

2.8.5 Data Transfer in I²C bus Mode

(1) Device Initialization

First, set the ACK in the SBICR1 to "1", the BC to "000", and the data length to 8-bit to count a clock pulse for the acknowledge signal. In addition, set the transmit frequency to the SCK.

Next, set the slave address to the SA in the I2CAR. Clear the ALS to "0" to set the addressing format.

After confirming that the serial bus interface pin is high level, for specifying the default setting to a slave receiver mode, clear "0" to the MST, TRX, and BB in the SBICR2; "1" to the PIN; "10" to the SBIM; and "0" to bits 1 and 0.

Note : To initialize the serial bus interface circuit, a constant period that the start conditions are not generated for any device is required after all devices which are connected to the bus are initialized. Then, the initialization must be completed during the period. If not, other devices may start transmitting data before the serial bus interface circuit has been initialized. Thus, data can not be normally received.

(2) Start Condition and Slave Address Generation

Confirm a bus free status (when BB = 0).

Set the ACK to "1" and specify a slave address and a direction bit to be transmitted to the SBIDBR.

When the BB is "0", the start condition are generated and the slave address and the direction bit which are set to the SBIDBR are output on a bus by writing "1" to the MST, TRX, BB, and PIN. An INTSBI interrupt request occurs at the 9th falling edge of the SCL clock cycle, and the PIN is cleared to "0". The SCL pin is pulled down to the low level while the PIN is "0". When an interrupt request occurs, the TRX changes by the hardware according to the direction bit only when an acknowledge signal is returned from the slave device.

Note 1 : The slave address to be output to the SBIDBR must be set after the bus free is detected by software. If setting of the slave address is executed before detection bus free, the current output data may be corrupted.

Note 2 : The bus free must be confirmed by software within 98.0 μ s (the shortest transmitting time according to the I2C bus standard) after setting of the slave address to be output. Only when the bus free is confirmed, set "1" to the MST, TRX, BB, and PIN to generate the start conditions. If the start conditions are generated without writing "1" to them, transferring may be executed by other masters between the time when the slave address to be output to the SBIDBR is written and the time when "1" is written to the MST, TRX, BB, and PIN in the SBICR2. Thus, the slave address may be corrupted.

Figure 2-32. Start Condition Generation and Slave Address Transfer

(3) 1-word Data Transfer

Check the MST by the INTSBI interrupt process after a 1-word data transfer is completed, and determine whether the mode is a master or slave.

a. When the MST is "1" (Master mode)

Check the TRX and determine whether the mode is a transmitter or receiver.

① When the TRX is "1" (Transmitter mode)

Check the LRB. When the LRB is "1", a receiver does not request data. Implement the process to generate a stop condition (Refer to 2.8.5. (4)) and terminate data transfer.

When the LRB is "0", the receiver requests new data. When the next transmitted data is other than 8 bits, set the BC and write the transmitted data to the SBIDBR. After writing the data, the PIN becomes "1", a serial clock pulse is generated for transferring a new 1-word of data from the SCL pin, and then the 1-word data is transmitted. After the data is transmitted, an INTSBI interrupt request occurs. The PIN becomes "0" and the SCL pin is pulled down to the low-level. If the data to be transferred is more than one word in length, repeat the procedure from the LRB checking above.

Figure 2-33. Example when BC = "000", ACK = "1" in Transmitter Mode

② When the TRX is "0" (Receiver mode)

When the next transmitted data is other than 8 bits, set the BC again. Set the ACK to "1" and read the received data from the SBIDBR (data which is read immediately after a slave address is sent is undefined). After the data is read, the PIN becomes "1". The 87C409/809 output a serial clock pulse to the SCL to transfer new 1-word of data and sets the SDA pin to "0" at the acknowledge signal timing.

An INTSBI interrupt request then occurs and the PIN becomes "0". Then the 87C409/809 pull down the SCL pin to the low level. The 87C409/809 output a clock pulse for 1-word of data transfer and the acknowledge signal each time that received data is read from the SBIDBR.

Figure 2-34. Example of when BC = "000", ACK = "1" in Receiver Mode

In order to terminate transmitting data to a transmitter, clear the ACK to "0" before reading data which is 1 word before the last data to be received. The last data does not generate a clock pulse for the acknowledge signal. After the data is transmitted and an interrupt request has occurred, set the BC to "001" and read the data. The 87C409/809 generate a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA line of the bus keeps the high level. The transmitter receives the high-level signal as an ACK signal. The receiver indicates to the transmitter that data transfer is complete.

After 1-bit data is received and an interrupt request has occurred, the 87C409/809 generate a stop condition (Refer to 2.8.5 (4)) and terminates data transfer.

Figure 2-35. Termination of Data Transfer in Master Receiver Mode

b. When the MST is "0" (Slave mode)

In the slave mode, the 87C409/809 operate either in normal slave mode or in slave mode after losing arbitration.

In the slave mode, an INTSBI interrupt request occurs when the 87C409/809 receive a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is complete after matching a received slave address. In the master mode, the 87C409/809 operate in a slave mode if it is losing arbitration. An INTSBI interrupt request occurs when word data transfer terminates after losing arbitration. When an INTSBI interrupt request occurs, the PIN (bit 4 in the SBICR2) is reset, and the SCL pin is pulled down to the low level. Either reading/writing from/to the SBIDBR or setting the PIN to "1" releases the SCL pin after taking t_{LOW} time.

Check the AL (bit 3 in the SBISR), the TRX (bit 6 in the SBISR), the AAS (bit 2 in the SBISR), and the AD0 (bit 1 in the SBISR) and implements processes according to conditions listed in the next table.

Table 2-7. Operation in the Slave Mode

TRX	AL	AAS	AD0	Conditions	Process
1	1	1	0	The 87C409/809 loses arbitration when transmitting a slave address and receives a slave address of which the value of the direction bit sent from another master is "1".	Set the number of bits in 1 word to the BC and write transmitted data to the SBIDBR.
	0	1	0	In the slave receiver mode, the 87C409/809 receives a slave address of which the value of the direction bit sent from the master is "1".	
		0	0	In the slave transmitter mode, 1-word data is transmitted.	Check the LRB. If the LRB is set to "1", set the PIN to "1" since the receiver does not request next data. Then, clear the TRX to "0" release the bus. If the LRB is cleared to "0", set the number of bits in a word to the BC and write transmitted data to the SBIDBR since the receiver requests next data.
0	1	1	1/0	The 87C409/809 lose arbitration when transmitting a slave address and receives a slave address or GENERAL CALL of which the value of the direction bit sent from another master is "0".	Read the SBIDBR for setting the PIN to "1" (reading dummy data) or write "1" to the PIN.
		0	0	The 87C409/809 loses arbitration when transmitting a slave address or data and terminates transferring word data.	
	0	1	1/0	In the slave receiver mode, the 87C409/809 receives a slave address or GENERAL CALL of which the value of the direction bit sent from the master is "0".	
		0	1/0	In the slave receiver mode, the 87C409/809 terminates receiving of 1-word data.	Set the number of bits in a word to the BC and read received data from the SBIDBR.

(4) Stop Condition Generation

When a stop condition is generated and a bus SCL line is set to low level by the other devices, a stop condition is not started normally.

Write "1" to the MST, TRX, and PIN, and "0" to the BB to generate a stop condition after releasing the SCL line.

Note : When a stop condition is generated, a time to rise the SCL line should not exceed $tr = 2^n / fc - 3.5 \times 4 / fc$ (2). (n depends on the SCK.)

If the rising time of the SCL line exceeds the above value, there is a probability that a stop condition is not started normally.

SCK	n	tr (Max., fc = 8 MHz)	tr (Max., fc = 4 MHz)

(5) Restart

Restart is used to change the direction of data transfer between a master device and a slave device during transferring data. The following explains how to restart when the 87C409/809 is in the master mode.

Clear "0" to the MST, TRX, and BB and set "1" to the PIN and release the bus. The SDA pin retains the high level and the SCL pin is released. Since a stop condition is not generated on a bus, a bus is assumed to be in a busy state from other devices. Check the BB until it becomes "0" to check that the SCL pin of the 87C409/809 is released. Check the LRB until it becomes "1" to check that the SCL line of a bus is not pulled down to the low level by other devices. After confirming that a bus stays in a free state, generate a start condition with procedure 2.8.5. (2).

In order to meet setup time when restarting, take at least 4.7 [μ s] of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

Figure 2-38. Control Register / Data Buffer Register / Status Register in SIO Mode

(1) Serial clock

a. Clock source

The SCK(bits 2 to 0 in SBICR1) is used to select the following functions.

① Internal clock

In an internal clock mode, any of seven frequencies can be selected. The serial clock is output to the outside on the $\overline{\text{SCK}}$ pin. The $\overline{\text{SCK}}$ pin becomes a high level when data transfer starts. When writing (in the transmit mode) or reading (in the receive mode) data cannot follow the serial clock rate, an automatic-wait function is executed to stop the serial clock automatically and hold the next shift operation until reading or writing is complete.

Figure 2-39. Automatic Wait Function

② External clock (SCK = "111")

An external clock supplied to the $\overline{\text{SCK}}$ pin is used as the serial clock. In order to ensure shift operation, a pulse width of at least 4 machine cycles is required for both high and low levels in the serial clock. The maximum data transfer frequency is 250 kHz ($f_c = 8$ MHz).

Figure 2-40. The Maximum Data Transfer Frequency in The External Clock Input

b. Shift edge

The leading edge is used to transmit data, and the trailing edge is used to receive data.

① Leading edge

Data is shifted on the leading edge of the serial clock (at a falling edge of the $\overline{\text{SCK}}$ pin input / output).

② Trailing edge

Data is shifted on the trailing edge of the serial clock (at a rising edge of the $\overline{\text{SCK}}$ pin input / output).

Figure 2-41. Shift Edge

(2) Transfer mode

The SIOM (bits 5 and 4 in SBICR) is used to select a transmit, receive, or transmit/receive mode.

a. 8-bit transmit mode

Set a control register to a transmit mode and write data to the SBIDBR.

After the data is written, set the SIOS to "1" to start data transfer. The transmitted data is transferred from the SBIDBR to the shift register and output to the SO pin in synchronous with the serial clock, starting from the least significant bit (LSB). When the data is transferred to the shift register, the SBIDBR becomes empty. The INTSBI (buffer empty) interrupt request is generated to request new data.

When the internal clock is used, the serial clock will stop and automatic-wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new data is written, automatic-wait function is canceled.

When the external clock is used, data should be written to the SBIDBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to the SBIDBR by the interrupt service program.

Transmitting data is ended by clearing SIOS to "0" or setting SIOINH to "1" buffer empty interrupt service program. When the SIOS is cleared, the transmitted mode ends when all data is output. In order to confirm if data is surely transmitted by the program, set the SIOF (bit 3 in the SBISR) to be sensed. The SIOF is cleared to "0" when transmitting is complete. When SIOINH is set, the transmission is immediately ended and SIOF is cleared to "0".

Figure 2-42. Transfer Mode

Example: SIO transfer end command (External clock)

```

STEST1 : TEST (SBISR).SEF      ; If SEF = 1 then loop
        JRS F,STEST1
STEST2 : TEST (P4).0           ; If  $\overline{SCK}$  = 0 then loop
        JRS T,STEST2
LD (SBICR1),00000111B        ; SIOS ← 0
  
```

Figure 2-43. Transmitted Data Hold Time at End of Transmit

b. 8-bit receive mode

Set a control register to a receive mode and the SIOS to "1" for switching to a receive mode. Data is received from the SI pin to the shift register in synchronous with the serial clock, starting from the least significant bit (LSB). When the 8-bit data is received, the data is transferred from the shift register to the SBIDBR. The INTSBI (buffer full) interrupt request is generated to request of reading the received data. The data is then read from the SBIDBR by the interrupt service program.

When the internal clock is used, the serial clock will stop and automatic-wait function will be initiated until the received data is read from the SBIDBR.

When the external clock is used, since shift operation is synchronized with the clock pulse provided externally, the received data should be read before new data is transferred to the SBIDBR. If the received data is not read, further data to be received is canceled. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when received data is read.

The receiving is ended by clearing SIOS to "0" or setting SIOINH to "1" in buffer full interrupt service program. When SIOINH is set, the receiving is immediately ended and SIOF is cleared to "0". When the SIOS is cleared, received data is transferred to the SBIDBR in complete blocks. The received mode ends when the transfer is complete. In order to confirm if data is surely received by the program, set the SIOF (bit 3 in SBIDBR) to be sensed. The SIOF is cleared to "0" when receiving is complete. After confirming that receiving has ended, the last data is read. When the SIOINH is set, receiving data stops. The SIOF turns "0" (the received data becomes invalid, therefore no need to read it).

Note : When the transfer mode is switched, the SBIDBR contents are lost. In case that the mode needs to be switched, conclude receiving data by clearing the SIOS to "0", read the last data, and then switch the mode.

Figure 2-44. Receive Mode (Example: Internal clock)

c. 8-bit transmit / receive mode

Set a control register to a transmit / receive mode and write data to the SBIDBR. After the data is written, set the SIOS to "1" to start transmitting / receiving. When transmitting, the data is output from the SO pin on the leading edges in synchronous with the serial clock, starting from the least significant bit (LSB). When receiving, the data is input to the SI pin on the trailing edges of the serial clock. 8-bit data is transferred from the shift register to the SBIDBR, and the INTSBI interrupt request occurs. The interrupt service program reads the received data from the shift register to the SBIDBR, and the INTSBI interrupt request occurs. The interrupt service program reads the received data from the data buffer register and writes data to be transmitted. The SBIDBR is used for both transmitting and receiving. Transmitted data should always be written after received data is read.

When the internal clock is used, automatic-wait function is initiated until received data is read and next data is written.

When the external clock is used, since the shift operation is synchronized with the external clock, received data is read and transmitted data is written before new shift operation is executed. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when received data is read and transmitted data is written.

Transmitting / receiving data is ended by cleaning the SIOS to "0" or setting SIOINH to "1" in interrupt service program. When the SIOS is cleared, received data is transferred to the SBIDBR in complete blocks. The transmit / receive mode ends when the transfer is completed. In order to confirm if data is surely transmitted / received by the program, set the SIOF (bit 3 in SBISR) to be sensed. The SIOF becomes "0" after transmitting / receiving is complete.

When SIOINH is set, the transmit / receive operation is immediately ended and SIOF is cleared to "0".

Note : When the transfer mode is switched, the SBIDBR contents are lost. In case that the mode needs to be switched, conclude transmitting/receiving data by clearing the SIOS to '0', read the last data, and then switch the transfer mode.

Figure 2-45. Transmit / Receive Mode (Example: Internal clock)

Figure 2-46. Transmitted Data Hold Time at End of Transmit / Receive

2.9 Oscillation Stop Detector

The TMP87C409/809 each have a Oscillation Stop Detector.
If the oscillation stops for any cause, P51 (CLZ1) or P50 (CLZ0) becomes high-impedance.

*Note : On the emulator, when Oscillation Stop Detector is enabled, P50 or P51 may become high-impedance by break instruction or single step instruction.
Release of break instruction or single step instruction returns the port in condition before high-impedance.*

2.9.1 Configuration

Figure 2-47. Oscillation Stop Detector

2.9.2 Control

The Oscillation Stop Detector is controlled by register (CLZCR).

Oscillation Stop Detector										
CLZCR (0028 _H)	7	6	5	4	3	2	1	0		
						STOPCR	P51CR	P50CR	(Initial value **** *000)	
STOPCR	Detection output control in STOP mode					0 : Enable in STOP mode 1 : Disable in STOP mode				write only
P51CR	P51 detection output control					0 : P51 detection enable 1 : P51 detection disable				
P50CR	P50 detection output control					0 : P50 detection enable 1 : P50 detection disable				
Note 1 : * ; don't care										
Note 2 : CLZCR is write-only register, therefore, it cannot be operated with read modify commands (SET, CLR and other bit operation commands : AND, OR and other multiplication commands).										

Figure 2-48. Oscillation Stop Detector Control Register

2.9.2 Function

If the oscillation stops for any cause, P51 (CLZ1) or P50 (CLZ0) becomes high-impedance.

When P51 or P50 used as a oscillation stop detector output, the output pins should be set to output mode beforehand the output latch should be set to "1" or "0".

P51/P50 output is selected by P51CR and P50CR (bit 1 and 0 in CLZCR). In STOP mode, the oscillation stop detection can be disabled be setting STOPCR to "1" (bit 2 in CLZCR).

Figure 2-49. Oscillation Stop Detector Timing Chart

2.10 10-bit A/D Converter (ADC)

The 87C409/809 have a 10-bit successive approximate type A/D converter.

Analog reference power supply (VAREF) is automatically cut off in stop mode or analog input disable.

2.10.1 Configuration

Figure 2-51. A/D Converter

2.10.2 Control

The A/D converter is controlled by an A/D converter control register (ADCCR) and an analog reference power supply select register (SELREF).

Reading EOCF of ADCCR recognizes A/D converter operation state, and reading A/D conversion result registers (ADCDRH, ADCDRL) recognize A/D conversion result.

Figure 2-52. A/D Conversion Result Register

2.10.3 Operation

The high side of an analog reference voltage is applied to VAREF pin, and the low side is applied to VASS pin. VAREF can be selected either VDD or P67 by SREF (bit 7 in SELREF). The reference voltage between VAREF and VASS is divided into the voltage corresponding with bits by radar resistance. The reference voltage is compared with an analog input voltage and A/D conversion is performed.

Note : VASS is the same as VSS.

(1) Start of A/D conversion

First, selects one of analog input channels (AIN7 to AIN0) by SAIN(bit 3 to 0 in ADCCR). Clear the AINDS (bit 4 in ADCCR) to "0". The channel used as an analog input is cleared to "0" by P6 input control (P6CR).

Note : The pin that is not used as an analog input can be used as regular input/output pins. During conversion, do not perform output instruction to maintain a precision for all of the pins.

A/D conversion is started by setting the ADS (bit 6 in ADCCR) to "1".

A/D conversion time is from A/D conversion until setting the conversion result to ADCDR. When ACK = 00, conversion is accomplished in $216/f_c$ [s] (54 machine cycles). For example, $27 \mu\text{s}$ in $f_c = 8 \text{ MHz}$. The EOCF (bit 7 in ADCCR) is set to "1" at end of conversion. When ADS is set to "1" during A/D conversion, conversion is initialized and restarted. Sampling of an analog input voltage is performed in 4 machine cycles after A/D conversion start is indicated.

(2) Reading of A/D conversion result

After the end of conversion (EOCF = 1), read the conversion result from the ADCDR. The EOCF is automatically cleared to "0" when reading the ADCDR. When the conversion result is read out during A/D conversion, the invalid value is read out.

(3) A/D conversion in STOP mode

When the MCU places in the STOP mode during the A/D conversion, the conversion is terminated and the A/D conversion value become indefinite. Thus EOCF is maintained to "0" after returned from the STOP mode. However, if the STOP mode is started after the end of A/D conversion (EOCF = "1"), the A/D conversion value and EOCF state are held.

Figure 2-53. A/D Conversion Timing Chart

Example 1 After AIN pin 4 is selected as an analog input channel, and conversion time is selected 216/fc [s] A/D conversion is started. EOCF is confirmed and the converted result is read out. It is saved to addresses 009D_H – 009E_H in RAM.

Supply Current in NORAML mode			V _{DD} = 3.0V f _c = 4.2 MHz V _{IN} = 2.8V/0.2V		2.5	3.5	mA
Supply Current in IDLE mode					1.5	2.0	
Supply Current in STOP mode			V _{DD} = 5.5V V _{IN} = 5.3V/0.2V		0.5	10	μA

Note 1 : Typical values show those at T_{opr} = 25 °C, V_{DD} = 5V.

Note 2 : Input Current I_{IN1}, I_{IN3} : The current through resistor is not included, when the input resistor (pull-up or pull-down) is contained.

A/D CONVERSION CHARACTERISTICS

(T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Analog Reference Voltage	V _{AREF}		2.2	—	V _{DD}	V
	V _{ASS}		V _{SS}			
Analog Input Voltage range	V _{AIN}		V _{ASS}	—	V _{AREF}	V
Analog Reference Current	I _{REF}	V _{AREF} = 5.5V, V _{ASS} (V _{SS}) = 0.0V	—	0.5	1.0	mA
Nonlinearity Error		V _{DD} = 5.0V V _{AREF} = 5.000V V _{ASS} (V _{SS}) = 0.000V or	—	—	± 2	LSB
Zero Point Error		V _{DD} = 2.2V V _{AREF} = 2.200V V _{ASS} (V _{SS}) = 0.000V	—	—	± 2	
Full Scale Error			—	—	± 2	
Total Error			—	—	± 4	

Note : Quantizing error is not contained in those errors.

OSCILLATION STOP DETECTOR CHARACTERISTICS

(V_{SS} = 0V, Topr = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Detection time	T _{CLZ}	VDD = 2.2V~5.5V (fc = 2 MHz~4.2 MHz) VDD = 4.5V~5.5 (fc = 8 MHz)	–	T.B.D.	–	μs

A.C. CHARACTERISTICS

(V_{SS} = 0 V, V_{DD} = 4.5 to 5.5 V, Topr = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Machine Cycle Time	tcy	In NORMAL mode	0.5	–	4	μs
		In IDLE mode				
High Level Clock Pulse Width	t _{WCH}	For external clock operation fc = 8 MHz	50	–	–	ns
Low Level Clock Pulse Width	t _{WCL}					

RECOMMENDED OSCILLATING CONDITIONS

(V_{SS} = 0 V, V_{DD} = 2.2 to 5.5 V, Topr = – 30 to 70 °C)

PARAMETER	Oscillator	Oscillation Frequency	Recommended Oscillator	Recommended Constant	
				C ₁	C ₂
High-frequency Oscillation	Ceramic Resonator	8 MHz (4.5 V to 5.5 V)	MURATA CST8.00MTW	—	
			MURATA CSA8.00MTZ	30 pF	30 pF
		4 MHz (2.2 V to 5.5 V)	MURATA CST4.00MGWU	—	
			MURATA CSA4.00MGU	30 pF	30 pF

(1) High-frequency Oscillation

Note: When used in high electric field such as a picture tube, the package is recommended to be electrically shielded to maintain a regular operation.

ELECTRICAL CHARACTERISTICS

ABSOLUTE MAXIMUM RATINGS

(V_{SS} = 0V)

PARAMETER		SYMBOL	CONDITION	RATINGS	UNIT
Supply Voltage		V _{DD}		– 0.3 to 6.5	V
Input Voltage		V _{IN}		– 0.3 to V _{DD} + 0.3	V
Output Voltage		V _{OUT1}	Ports P1, P5, P6, XOUT	– 0.3 to V _{DD} + 0.3	
		V _{OUT2}	Port P4	– 0.3 to 5.5	V
Output Current (Per 1 pin)	I _{OL}	I _{OUT1}	Ports P1, P6	3.2	mA
		I _{OUT2}	Ports P4, P5	30	
	I _{OH}	I _{OUT3}	Ports P1, P5, P6	– 1.8	mA
Output Current (Total)	I _{OL}	Σ I _{OUT1}	Ports P1, P6	30	mA
		Σ I _{OUT2}	Ports P4, P5	80	
	I _{OH}	Σ I _{OUT3}	Ports P1, P5, P6	30	
Power Dissipation [T _{opr} = 70 °C]		PD	SDIP	300	mW
			SOP	180	
Soldering Temperature (time)		T _{sld}		260 (10 s)	°C
Storage Temperature		T _{stg}		– 55 to 125	°C
Operating Temperature		T _{opr}		– 30 to 70	°C

RECOMMENDED OPERATING CONDITIONS

(V_{SS} = 0V, T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	PINS	CONDITIONS	Min.	Max.	UNIT
Supply Voltage	V _{DD}		fc = 8 MHz	4.5	5.5	V
			NORMAL mode			
			IDLE mode			
			fc = 4.2 MHz	2.2		
Input High Voltage	V _{IH1}	Except hysteresis input	V _{DD} ≥ 4.5V	V _{DD} × 0.70	V _{DD}	V
	V _{IH2}	Hysteresis input		V _{DD} × 0.75		
	V _{IH3}		V _{DD} < 4.5V	V _{DD} × 0.90		
Input Low Voltage	V _{IL1}	Except hysteresis input	V _{DD} ≥ 4.5V	0	V _{DD} × 0.30	V
	V _{IL2}	Hysteresis input			V _{DD} × 0.25	
	V _{IL3}		V _{DD} < 4.5V		V _{DD} × 0.10	
Clock Frequency	fc	XIN, XOUT	V _{DD} = 4.5 to 5.5V	1.0	8.0	MHz
			V _{DD} = 2.2 V to 5.5 V		4.2	

Note1 : Clock frequency fc : Supply voltage range is specified in NORMAL mode and IDLE mode.

D.C. CHARACTERISTICS

(V_{SS} = 0V, T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	PINS	CONDITIONS	Min.	Typ.	Max.	UNIT
Hysteresis Voltage	V _{HS}	Hysteresis input		–	0.9	–	V
Input Current	I _{IN1}	TEST	V _{DD} = 5.5V	–	–	± 2	μA
	I _{IN2}	Tri-state ports	V _{IN} = 5.5V/0V				
	I _{IN3}	RESET, STOP					
Input Resistance	R _{IN2}	RESET		100	220	450	KΩ
Output Leakage Current	I _{LO}	Tri-state ports	V _{DD} = 5.5V, V _{OUT} = 5.5V/0V	– 2	–	2	μA
Output High Voltage	V _{OH2}	Tri-state ports	V _{DD} = 4.5V, I _{OH} = – 0.7 mA	4.1	–	–	V
Output Low Voltage	V _{OL1}	Except XOUT, P4 and P5	V _{DD} = 4.5V, I _{OL} = 1.6 mA	–	–	0.4	
Output Low current	I _{OL3}	P4, P5	V _{DD} = 4.5V, V _{OL} = 1.0V	–	20	–	mA
Supply Current in NORMAL modes	I _{DD}		V _{DD} = 5.5V f _c = 8 MHz V _{IN} = 5.3V/0.2V		8	14	mA
Supply Current in IDLE modes					4	6	
Supply Current in NORAML mode			V _{DD} = 3.0V f _c = 4.2 MHz V _{IN} = 2.8V/0.2V		2.5	3.5	mA
Supply Current in IDLE mode					1.5	2.0	
Supply Current in STOP mode			V _{DD} = 5.5V V _{IN} = 5.3V/0.2V		0.5	10	μA

Note 1 : Typical values show those at T_{opr} = 25 °C, V_{DD} = 5V.

Note 2 : Input Current I_{IN1}, I_{IN3} : The current through resistor is not included, when the input resistor (pull-up or pull-down) is contained.

A/D CONVERSION CHARACTERISTICS

(T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Analog Reference Voltage	V _{AREF}		2.2	—	V _{DD}	V
	V _{ASS}		V _{SS}			
Analog Input Voltage range	V _{AIN}		V _{ASS}	—	V _{AREF}	V
Analog Reference Current	I _{REF}	V _{AREF} = 5.5V, V _{ASS} (V _{SS}) = 0.0V	—	0.5	1.0	mA
Nonlinearity Error		V _{DD} = 5.0V V _{AREF} = 5.000V V _{ASS} (V _{SS}) = 0.000V or	—	—	± 2	LSB
Zero Point Error		V _{DD} = 2.2V V _{AREF} = 2.200V V _{ASS} (V _{SS}) = 0.000V	—	—	± 2	
Full Scale Error			—	—	± 2	
Total Error			—	—	± 4	

Note : Quantizing error is not contained in those errors.

OSCILLATION STOP DETECTOR CHARACTERISTICS

(V_{SS} = 0V, T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Detection time	T _{CLZ}	VDD = 2.2V~5.5V (f _c = 2 MHz~4.2 MHz) VDD = 4.5V~5.5 (f _c = 8 MHz)	–	T.B.D.	–	μs

A.C. CHARACTERISTICS

(V_{SS} = 0 V, V_{DD} = 4.5 to 5.5 V, T_{opr} = – 30 to 70 °C)

PARAMETER	SYMBOL	CONDITIONS	Min.	Typ.	Max.	UNIT
Machine Cycle Time	t _{cy}	In NORMAL mode	0.5	–	4	μs
		In IDLE mode				
High Level Clock Pulse Width	t _{WCH}	For external clock operation f _c = 8 MHz	50	–	–	ns
Low Level Clock Pulse Width	t _{WCL}					

RECOMMENDED OSCILLATING CONDITIONS

(V_{SS} = 0 V, V_{DD} = 2.2 to 5.5 V, T_{opr} = – 30 to 70 °C)

PARAMETER	Oscillator	Oscillation Frequency	Recommended Oscillator	Recommended Constant	
				C ₁	C ₂
High-frequency Oscillation	Ceramic Resonator	8 MHz (4.5 V to 5.5 V)	MURATA CST8.00MTW	—	
			MURATA CSA8.00MTZ	30 pF	30 pF
		4 MHz (2.2 V to 5.5 V)	MURATA CST4.00MGWU	—	
			MURATA CSA4.00MGU	30 pF	30 pF

(1) High-frequency Oscillation

Note: When used in high electric field such as a picture tube, the package is recommended to be electrically shielded to maintain a regular operation.
