

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

### General Description

The MAX9750/MAX9751/MAX9755 combine a stereo, 2.6W audio power amplifier and stereo DirectDrive 110mW headphone amplifier in a single device. The headphone amplifier uses Maxim's patented DirectDrive architecture that produces a ground-referenced output from a single supply, eliminating the need for large DC-blocking capacitors, saving cost, space, and component height. A high 90dB PSRR and low 0.01% THD+N ensures clean, low-distortion amplification of the audio signal.

The MAX9750 features an analog volume control, and a BEEP input. The MAX9751 features a 2:1 input multiplexer, allowing multiple audio sources to be selected. All devices feature a single-supply voltage, a shutdown mode, logic-selectable gain, and a headphone sense input. Industry-leading click-and-pop suppression eliminates audible transients during power and shutdown cycles.

The MAX9750/MAX9751/MAX9755 are offered in space-saving, thermally efficient 28-pin thin QFN (5mm x 5mm x 0.8mm) and 28-pin TSSOP packages. Both devices have thermal-overload and output short-circuit protection, and are specified over the extended -40°C to +85°C temperature range.

### Applications

Notebook PCs

Flat-Panel TVs

Tablet PCs

PC Displays

Portable DVD Players

LCD Projectors

### Simplified Block Diagrams

### Features

- ◆ **No DC-Blocking Capacitors Required—Provides Industry's Most Compact Notebook Audio Solution**
- ◆ **PC2001 Compliant**
- ◆ **5V Single-Supply Operation**
- ◆ **Class AB 2.6W Stereo BTL Speaker Amplifiers**
- ◆ **110mW DirectDrive Headphone Amplifiers**
- ◆ **High 90dB PSRR**
- ◆ **Low-Power Shutdown Mode**
- ◆ **Industry-Leading Click-and-Pop Suppression**
- ◆ **Low 0.01% THD+N at 1kHz**
- ◆ **Short-Circuit and Thermal Protection**
- ◆ **Selectable Gain Settings**
- ◆ **Analog Volume Control (MAX9750)**
- ◆ **Beep Input with Glitch Filter (MAX9750)**
- ◆ **2:1 Stereo Input MUX (MAX9751)**
- ◆ **±8kV ESD-Protected Headphone Driver Outputs**
- ◆ **Available in Space-Saving, Thermally Efficient Packages**
  - 28-Pin Thin QFN (5mm x 5mm x 0.8mm)
  - 28-Pin TSSOP

**MAX9750/MAX9751/MAX9755**

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

Figure 1. MAX9750/MAX9751 Signal Path

Figure 2. Traditional Headphone Amplifier Output Waveform vs. DirectDrive Headphone Amplifier Output Waveform

### Detailed Description

The MAX9750/MAX9751/MAX9755 combine a 2.6W BTL speaker amplifier and a 110mW DirectDrive headphone amplifier with integrated headphone sensing and comprehensive click-and-pop suppression. The MAX9750 features an analog volume control, BEEP input, and four-level gain control. The MAX9751 features a 2:1 input stereo multiplexer and two-level gain control. All devices feature high 90dB PSRR, low 0.01% THD+N, industry-leading click-pop performance, and a low-power shutdown mode.

Each signal path consists of an input amplifier that sets the gain of the signal path and feeds both the speaker and headphone amplifier (Figure 1). The speaker amplifier uses a BTL architecture, doubling the voltage drive to the speakers and eliminating the need for DC-blocking capacitors. The output consists of two signals, identical in magnitude, but 180° out of phase.

The headphone amplifiers use Maxim's patented DirectDrive architecture that eliminates the bulky output DC-blocking capacitors required by traditional headphone amplifiers. A charge pump inverts the positive supply (CPVDD), creating a negative supply (CPVss). The headphone amplifiers operate from these bipolar supplies with their outputs biased about GND (Figure 2).

The amplifiers have almost twice the supply range compared to other single-supply amplifiers, nearly quadrupling the available output power. The benefit of the GND bias is that the amplifier outputs no longer have a DC component (typically  $V_{DD} / 2$ ). This eliminates the large DC-blocking capacitors required with conventional headphone amplifiers, conserving board space and system cost, and improving frequency response.

The MAX9750 features an analog volume control that varies the gain of the amplifiers based on the DC voltage applied at VOL. Both devices feature an undervoltage lockout that prevents operation from an insufficient power supply and click-and-pop suppression that eliminates audible transients on startup and shutdown. The amplifiers include thermal-overload and short-circuit protection, and can withstand  $\pm 8\text{ kV}$  ESD strikes on the headphone amplifier outputs (IEC air discharge). An additional feature of the speaker amplifiers is that there is no phase inversion from input to output.

### DirectDrive

Conventional single-supply headphone amplifiers have their outputs biased about a nominal DC voltage (typically half the supply) for maximum dynamic range. Large coupling capacitors are needed to block this DC bias from the headphones. Without these capacitors, a

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

significant amount of DC current flows to the headphone, resulting in unnecessary power dissipation and possible damage to both headphone and headphone amplifier.

Maxim's patented DirectDrive architecture uses a charge pump to create an internal negative supply voltage. This allows the MAX9750/MAX9751/MAX9755 headphone amplifier output to be biased about GND, almost doubling the dynamic range while operating from a single supply. With no DC component, there is no need for the large DC-blocking capacitors. Instead of two large capacitors (220 $\mu$ F typ), the MAX9750/MAX9751/MAX9755 charge pump requires only two small ceramic capacitors (1 $\mu$ F typ), conserving board space, reducing cost, and improving the frequency response of the headphone amplifier. See the Output Power vs. Charge-Pump Capacitance and Load Resistance graph in the *Typical Operating Characteristics* for details of the possible capacitor values.

Previous attempts to eliminate the output coupling capacitors involved biasing the headphone return (sleeve) to the DC bias voltage of the headphone amplifiers. This method raised some issues:

- 1) The sleeve is typically grounded to the chassis. Using this biasing approach, the sleeve must be isolated from system ground, complicating product design.
- 2) During an ESD strike, the amplifier's ESD structures are the only path to system ground. The amplifier must be able to withstand the full ESD strike.
- 3) When using the headphone jack as a lineout to other equipment, the bias voltage on the sleeve may conflict with the ground potential from other equipment, resulting in large ground-loop current and possible damage to the amplifiers.

### Low-Frequency Response

In addition to the cost and size disadvantages, the DC-blocking capacitors limit the low-frequency response of the amplifier and distort the audio signal:

- 1) The impedance of the headphone load to the DC-blocking capacitor forms a highpass filter with the -3dB point determined by:

$$f_{-3dB} = \frac{1}{2\pi R_L C_{OUT}}$$

where  $R_L$  is the impedance of the headphone and  $C_{OUT}$  is the value of the DC-blocking capacitor.

The highpass filter is required by conventional single-ended, single-supply headphone amplifiers to block the midrail DC component of the audio signal from the headphones. Depending on the -3dB point,

Figure 3. Low-Frequency Attenuation of Common DC-Blocking Capacitor Values

the filter can attenuate low-frequency signals within the audio band. Larger values of  $C_{OUT}$  reduce the attenuation but are physically larger, more expensive capacitors. Figure 3 shows the relationship between the size of  $C_{OUT}$  and the resulting low-frequency attenuation. Note that the -3dB point for a 16 $\Omega$  headphone with a 100 $\mu$ F blocking capacitor is 100Hz, well within the audio band.

- 2) The voltage coefficient of the capacitor, the change in capacitance due to a change in the voltage across the capacitor, distorts the audio signal. At frequencies around the -3dB point, the reactance of the capacitor dominates, and the voltage coefficient appears as frequency-dependent distortion. Figure 4 shows the THD+N introduced by two different capacitor dielectrics. Note that around the -3dB point, THD+N increases dramatically.

The combination of low-frequency attenuation and frequency-dependent distortion compromises audio reproduction. DirectDrive improves low-frequency reproduction in portable audio equipment that emphasizes low-frequency effects such as multimedia laptops, and MP3, CD, and DVD players.

### Charge Pump

The MAX9750/MAX9751/MAX9755 feature a low-noise charge pump. The 550kHz switching frequency is well beyond the audio range, and does not interfere with the audio signals. The switch drivers feature a controlled switching speed that minimizes noise generated by turn-on and turn-off transients. Limiting the switching speed of the charge pump minimizes the di/dt noise caused by the

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

Figure 4. Distortion Contributed by DC-Blocking Capacitors

parasitic bond wire and trace inductance. Although not typically required, additional high-frequency ripple attenuation can be achieved by increasing the size of C2 (see the *Typical Application Circuit*).

### Headphone Sense Input (HPS)

The headphone sense input (HPS) monitors the headphone jack and automatically configures the device based upon the voltage applied at HPS. A voltage of less than 0.8V sets the device to speaker mode. A voltage of greater than 2V disables the bridge amplifiers and enables the headphone amplifiers.

For automatic headphone detection, connect HPS to the control pin of a 3-wire headphone jack as shown in Figure 5. With no headphone present, the output impedance of the headphone amplifier pulls HPS low. When a headphone plug is inserted into the jack, the control pin is disconnected from the tip contact and HPS is pulled to VDD through a 10µA current source.

### BIAS

The MAX9750/MAX9751/MAX9755 feature an internally generated, power-supply independent, common-mode bias voltage of 1.8V referenced to GND. BIAS provides both click-and-pop suppression and sets the DC bias level for the amplifiers. Choose the value of the bypass capacitor as described in the *BIAS Capacitor* section. No external load should be applied to BIAS. Any load lowers the BIAS voltage, affecting the overall performance of the device.

Figure 5. HPS Configuration

### Gain Selection

#### MAX9750

The MAX9750 features an internally set, selectable gain. The GAIN1 and GAIN2 inputs set the maximum gain of the MAX9750 speaker and headphone amplifiers (Table 1). The gain of the device can vary based upon the voltage at VOL (see the *Analog Volume Control* section). However, the maximum gain cannot be exceeded.

#### MAX9751/MAX9755

The gain of the MAX9751/MAX9755 is set by the GAIN input. Driving GAIN high sets the gain of the speaker amplifiers to 9dB and the gain of the headphone amplifiers to 0dB. Driving GAIN low sets the gain of the speaker amplifiers to 10.5dB, and the gain of the headphone amplifiers to 3dB (Table 2).

### Analog Volume Control (VOL)

The MAX9750 features an analog volume control that varies the gain of the device in 31 discrete steps based upon the DC voltage applied to VOL. The input range of VVOL is from 0 (full volume) to 0.858 x HPVDD (full mute), with example step sizes shown in Table 3. Connect the reference of the device driving VOL (Figure 6) to HPVDD. Since the volume control ADC is ratiometric to HPVDD, any changes in HPVDD are negated. The gain step sizes are not constant; the step sizes are 0.5dB/step at the upper extreme, 2dB/step in the midrange, and 4dB/step at the lower extreme. Figure 7 shows the transfer function of the volume control for a 3.3V supply.

**Table 2. MAX9751 Gain Settings**

GAIN	SPEAKER MODE GAIN (dB)	HEADPHONE MODE GAIN (dB)
0	10.5	3
1	9	0

## BEEP Input

The MAX9750 features an audible alert beep input (BEEP) that accepts a mono system alert signal and mixes it into the stereo audio path. When the amplitude of  $V_{BEEP(OUT)}$  exceeds 800mVp-p (Figure 8) and the frequency of the beep signal is greater than 400Hz, the beep signal is mixed into the active audio path (speaker or headphone). If the signal at  $V_{BEEP(OUT)}$  is either <800mVp-p or <400Hz, the BEEP signal is not mixed into the audio path. The amplitude of the BEEP signal at the device output is roughly the amplitude of  $V_{BEEP(OUT)}$  times the gain of the selected signal path.

The input resistor ( $R_B$ ) sets the gain of the BEEP input amplifier, and thus the amplitude of  $V_{BEEP(OUT)}$ . Choose  $R_B$  based on:

$$R_B \leq \frac{V_{IN} \times R_{INT}}{0.3}$$

where  $R_{INT}$  is the value of the BEEP amplifier feedback resistor ( $47k\Omega$ ) and  $V_{IN}$  is the BEEP input amplitude. Note that the BEEP amplifier can be set up as either an attenuator, if the original alert signal amplitude is too large, or set to gain up the alert signal if it is below 400mVp-p. AC couple the alert signal to BEEP. Choose the value of the coupling capacitor as described in the *Input Filtering* section. Multiple beep inputs can be summed (Figure 8).

Figure 6. Volume Control Circuit

## Input Multiplexer

The MAX9751 features a 2:1 input multiplexer on each amplifier, allowing input selection between two stereo sources. The logic input  $IN1/2$  controls both multiplexers. A logic high selects input  $IN\_1$  and a logic low selects input  $IN\_2$ .

## Shutdown

The MAX9750/MAX9751/MAX9755 features a 0.2 $\mu$ A, low-power shutdown mode that reduces quiescent current consumption and extends battery life. Driving  $SHDN$  low disables the drive amplifiers, bias circuitry, and charge pump, and drives  $BIAS$  and all outputs to GND. Connect  $SHDN$  to  $VDD$  for normal operation.

## Click-and-Pop Suppression

### Speaker Amplifier

The MAX9750/MAX9751/MAX9755 speaker amplifiers feature Maxim's comprehensive, industry-leading click-and-pop suppression. During startup, the click-pop suppression circuitry eliminates any audible transient sources internal to the device. When entering shutdown, both amplifier outputs ramp to GND quickly and simultaneously.

**MAX9750/MAX9751/MAX9755**

Figure 7a. Volume Control Transfer Function

Figure 7b. Volume Control Transfer Function

Figure 7c. Volume Control Transfer Function

### Headphone Amplifier

In conventional single-supply headphone amplifiers, the output-coupling capacitor is a major contributor of audible clicks and pops. Upon startup, the amplifier charges the coupling capacitor to its bias voltage, typically half the supply. Likewise, during shutdown, the capacitor is discharged to GND. A DC shift across the capacitor results, which in turn appears as an audible transient at the speaker. Since the MAX9750/MAX9751/MAX9755 do not require output-coupling capacitors, no audible transient occurs.

Additionally, the MAX9750/MAX9751/MAX9755 features extensive click-and-pop suppression that eliminates any audible transient sources internal to the device. The Power-Up/Down Waveform in the *Typical Operating Characteristics* shows that there are minimal spectral components in the audible range at the output upon startup and shutdown.

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

Figure 9. Bridge-Tied Load Configuration

Figure 10. Total Harmonic Distortion Plus Noise vs. Output Power with Inputs In/Out of Phase (Headphone Mode)

### Applications Information

#### BTL Speaker Amplifiers

The MAX9750/MAX9751/MAX9755 feature speaker amplifiers designed to drive a load differentially, a configuration referred to as bridge-tied load (BTL). The BTL configuration (Figure 9) offers advantages over the single-ended configuration, where one side of the load is connected to ground. Driving the load differentially doubles the output voltage compared to a single-ended amplifier under similar conditions. Thus, the device's differential gain is twice the closed-loop gain of the input amplifier. The effective gain is given by:

$$AVD = 2 \times \frac{R_F}{R_{IN}}$$

Substituting  $2 \times V_{OUT}(P-P)$  into the following equation yields four times the output power due to double the output voltage:

$$V_{RMS} = \frac{V_{OUT}(P-P)}{2\sqrt{2}}$$

$$P_{OUT} = \frac{V_{RMS}^2}{R_L}$$

Since the differential outputs are biased at midsupply, there is no net DC voltage across the load. This eliminates the need for DC-blocking capacitors required for single-ended amplifiers. These capacitors can be large and expensive, can consume board space, and can degrade low-frequency performance.

#### Power Dissipation and Heat Sinking

Under normal operating conditions, the MAX9750/MAX9751/MAX9755 can dissipate a significant amount of power. The maximum power dissipation for each package is given in the *Absolute Maximum Ratings* under Continuous Power Dissipation, or can be calculated by the following equation:

$$P_{DISSPKG(MAX)} = \frac{T_{J(MAX)} - T_A}{\theta_{JA}}$$

where  $T_{J(MAX)}$  is  $+150^\circ\text{C}$ ,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the reciprocal of the derating factor in  $^\circ\text{C}/\text{W}$  as specified in the *Absolute Maximum Ratings* section. For example,  $\theta_{JA}$  of the thin QFN package is  $+42^\circ\text{C}/\text{W}$ . For optimum power dissipation, the exposed paddle of the package should be connected to the ground plane (see the *Layout and Grounding* section).

For  $8\Omega$  applications, the worst-case power dissipation occurs when the output power is  $1.1\text{W}/\text{channel}$ , resulting in a power dissipation of about  $1\text{W}$ . In this case, both the TSSOP and TQFN packages can be used without violating the maximum power dissipation or exceeding the thermal protection threshold. For  $4\Omega$  applications, the TSSOP package may require heat-sinking or forced air cooling to prevent the device from reaching its thermal limit. The more thermally efficient TQFN package is suggested for speaker loads less than  $8\Omega$ .

#### Output Power (Speaker Amplifier)

The increase in power delivered by the BTL configuration directly results in an increase in internal power dissipation over the single-ended configuration. The

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

**Table 4. Suggested Capacitor Manufacturers**

SUPPLIER	PHONE	FAX	WEBSITE
Taiyo Yuden	800-348-2496	847-925-0899	<a href="http://www.t-yuden.com">www.t-yuden.com</a>
TDK	807-803-6100	847-390-4405	<a href="http://www.component.tdk.com">www.component.tdk.com</a>

maximum power dissipation for a given  $V_{DD}$  and load is given by the following equation:

$$P_{DISS(MAX)} = \frac{2V_{DD}^2}{\pi^2 R_L}$$

If the power dissipation for a given application exceeds the maximum allowed for a given package, either reduce  $V_{DD}$ , increase load impedance, decrease the ambient temperature, or add heatsinking to the device. Large output, supply, and ground PC board traces improve the maximum power dissipation in the package.

Thermal-overload protection limits total power dissipation in these devices. When the junction temperature exceeds  $+160^{\circ}\text{C}$ , the thermal-protection circuitry disables the amplifier output stage. The amplifiers are enabled once the junction temperature cools by  $15^{\circ}\text{C}$ . This results in a pulsing output under continuous thermal-overload conditions as the device heats and cools.

### Output Power (Headphone Amplifier)

The headphone amplifiers have been specified for the worst-case scenario—when both inputs are in phase. Under this condition, the drivers simultaneously draw current from the charge pump, leading to a slight loss in headroom of  $V_{SS}$ . In typical stereo audio applications, the left and right signals have differences in both magnitude and phase, subsequently leading to an increase in the maximum attainable output power. Figure 10 shows the two extreme cases for in and out of phase. In reality, the available power lies between these extremes.

### Power Supplies

The MAX9750/MAX9751/MAX9755 have different supplies for each portion of the device, allowing for the optimum combination of headroom and power dissipation and noise immunity. The speaker amplifiers are powered from  $PV_{DD}$ .  $PV_{DD}$  ranges from 4.5V to 5.5V. The headphone amplifiers are powered from  $HPV_{DD}$  and  $V_{SS}$ .  $HPV_{DD}$  is the positive supply of the headphone amplifiers and ranges from 3V to 5.5V.  $V_{SS}$  is the negative supply of the headphone amplifiers. Connect  $V_{SS}$  to  $CPV_{SS}$ . The charge pump is powered by  $CPV_{DD}$ .  $CPV_{DD}$  ranges from 3V to 5.5V and should be the same potential as  $HPV_{DD}$ . The charge pump inverts the voltage at  $CPV_{DD}$ , and the resulting voltage appears at  $CPV_{SS}$ . The remainder of the device is powered by  $V_{DD}$ .

### Component Selection

#### Input Filtering

The input capacitor ( $C_{IN}$ ), in conjunction with the amplifier input resistance ( $R_{IN}$ ), forms a highpass filter that removes the DC bias from an incoming signal (see the *Typical Application Circuit*). The AC-coupling capacitor allows the amplifier to bias the signal to an optimum DC level. Assuming zero source impedance, the  $-3\text{dB}$  point of the highpass filter is given by:

$$f_{-3\text{dB}} = \frac{1}{2\pi R_{IN} C_{IN}}$$

$R_{IN}$  is the amplifier's internal input resistance value given in the *Electrical Characteristics*. Choose  $C_{IN}$  such that  $f_{-3\text{dB}}$  is well below the lowest frequency of interest. Setting  $f_{-3\text{dB}}$  too high affects the amplifier's low-frequency response. Use capacitors with low-voltage coefficient dielectrics, such as tantalum or aluminum electrolytic. Capacitors with high-voltage coefficients, such as ceramics, may result in increased distortion at low frequencies.

#### BIAS Capacitor

BIAS is the output of the internally generated DC bias voltage. The BIAS bypass capacitor,  $C_{BIAS}$ , improves PSRR and THD+N by reducing power supply and other noise sources at the common-mode bias node, and also generates the clickless/popless, startup/shutdown DC bias waveforms for the speaker amplifiers. Bypass BIAS with a  $1\mu\text{F}$  capacitor to GND.

#### Charge-Pump Capacitor Selection

Use capacitors with an ESR less than  $100\text{m}\Omega$  for optimum performance. Low-ESR ceramic capacitors minimize the output resistance of the charge pump. For best performance over the extended temperature range, select capacitors with an X7R dielectric. Table 4 lists suggested manufacturers.

#### Flying Capacitor (C1)

The value of the flying capacitor (C1) affects the load regulation and output resistance of the charge pump. A C1 value that is too small degrades the device's ability to provide sufficient current drive, which leads to a loss of output voltage. Increasing the value of C1 improves load regulation and reduces the charge-pump output

## 2.6W Stereo Audio Power Amplifiers and DirectDrive Headphone Amplifiers

resistance to an extent. See the Output Power vs. Charge-Pump Capacitance and Load Resistance graph in the *Typical Operating Characteristics*. Above 2.2 $\mu$ F, the on-resistance of the switches and the ESR of C1 and C2 dominate.

### **Output Capacitor (C2)**

The output capacitor value and ESR directly affect the ripple at CPVss. Increasing the value of C2 reduces output ripple. Likewise, decreasing the ESR of C2 reduces both ripple and output resistance. Lower capacitance values can be used in systems with low maximum output power levels. See the Output Power vs. Charge-Pump Capacitance and Load Resistance graph in the *Typical Operating Characteristics*.

### **CPVDD Bypass Capacitor**

The CPVDD bypass capacitor (C3) lowers the output impedance of the power supply and reduces the impact of the MAX9750/MAX9751/MAX9755's charge-pump switching transients. Bypass CPVDD with C3, the same value as C1, and place it physically close to CPVDD and PGND (refer to the MAX9750 Evaluation Kit for a suggested layout).

### **Powering Other Circuits from a Negative Supply**

An additional benefit of the MAX9750/MAX9751/MAX9755 is the internally generated negative supply voltage (CPVss). CPVss is used by the MAX9750/MAX9751/MAX9755 to provide the negative supply for the headphone amplifiers. It can also be used to power other devices within a design. Current draw from CPVss should be limited to 5mA, exceeding this affects the operation of the headphone amplifier. A typical application is a negative supply to adjust the contrast of LCD modules.

When considering the use of CPVss in this manner, note that the charge-pump voltage of CPVss is roughly proportional to CPVDD and is not a regulated voltage. The charge-pump output impedance plot appears in the *Typical Operating Characteristics*.

### **Layout and Grounding**

Proper layout and grounding are essential for optimum performance. Use large traces for the power-supply inputs and amplifier outputs to minimize losses due to parasitic trace resistance, as well as route head away from the device. Good grounding improves audio performance, minimizes crosstalk between channels, and prevents any switching noise from coupling into the audio signal. Connect CPGND, PGND and GND together at a single point on the PC board. Route CPGND and all traces that carry switching transients away from GND, PGND, and the traces and components in the audio signal path.

Connect all components associated with the charge pump (C2 and C3) to the CPGND plane. Connect Vss and CPVss together at the device. Place the charge-pump capacitors (C1, C2, and C3) as close to the device as possible. Bypass HPVDD and PVDD with a 0.1 $\mu$ F capacitor to GND. Place the bypass capacitors as close to the device as possible.

Use large, low-resistance output traces. As load impedance decreases, the current drawn from the device outputs increase. At higher current, the resistance of the output traces decrease the power delivered to the load. For example, when compared to a 0 $\Omega$  trace, a 100m $\Omega$  trace reduces the power delivered to a 4 $\Omega$  load from 2.1W to 2W. Large output, supply, and GND traces also improve the power dissipation of the device.

The MAX9750/MAX9751/MAX9755 thin QFN package features an exposed thermal pad on its underside. This pad lowers the package's thermal resistance by providing a direct heat conduction path from the die to the printed circuit board. Connect the exposed thermal pad to GND by using a large pad and multiple vias to the GND plane.
