Am7968/Am7969

TAXIchip™ Integrated Circuits
(Transparent Asynchronous Xmitter – Receiver Interface)
PRELIMINARY

## DISTINCTIVE CHARACTERISTICS

- Parallel TTL bus interface
  - Eight Data and four Command Pins
  - or nine Data and three Command Pins
  - or ten Data and two Command Pins
- Transparent synchronous serial link
  - +5 V ECL Serial I/O
  - AC or DC coupled
  - NRZI 4B/5B, 5B/6B encoding/decoding
- Drive coaxial cable or twisted pair directly
- Easy interface with fiber optic data links
- 32-100 Mbps (4-12.5 Mbytes/sec) data throughput
- Asynchronous input using STRB/ACK
- Automatic MUX/DEMUX of Data and Command
- Cascadable for larger bus widths
- Complete on-chip PLL, Crystal Oscillator
- Single +5 V supply operation
- 28-pin PLCC, LCC or DIP

GENERAL DESCRIPTION

The Am7968 TAXIchip Transmitter and Am7969 TAXIchip Receiver Chipset is a general-purpose interface for very high-speed (4-12.5 Mbytes/sec, 40-125 Mbaud serially) point-to-point communications over coaxial or fiber-optic media. TAXIs emulate a pseudo-parallel register. They load data into one side and output it on the other, except in this case, the "other" side is separated by a long serial link.

The speed of a TAXIchip system is adjustable over a range of frequencies, with parallel bus transfer rates of 4 Mbytes/sec at the low end, and up to 12.5 Mbytes/sec at the high end. The TAXIchip's flexible bus interface scheme accepts bytes that are either 8, 9, or 10 bits wide. Multiple TAXIs can also be cascaded to accomodate a wider data bus. Byte transfers can be Data or Command signalling.

PIN DESCRIPTION

Am7968 TAXIchip Transmitter

$DI_0 - DI_7$ Parallel Data In (TTL Inputs)

These eight inputs accept parallel data from the host system, to be latched, encoded and transmitted.

DI_8/CI_3 Parallel Data (8) In or Command (3) In (TTL Input)

DI_8/CI_3 input is either Data or Command, depending upon the state of *DMS*.

DI_9/CI_2 Parallel Data (9) In or Command (2) In (TTL Input)

DI_9/CI_2 input is either Data or Command, depending upon the state of *DMS*.

$CI_0 - CI_1$ Parallel Command In (TTL Inputs)

These two inputs accept parallel command information from the host system. If one or more command bits are logic "1", the command bit pattern is latched, encoded, and transmitted in place of any pattern on the Data inputs.

STRB Input Strobe Signal (TTL Input)

A rising edge on the *STRB* input causes the Data *($DI_0 - DI_9$)* or the Command *($CI_0 - CI_3$)* inputs to be latched into the Am7968 Transmitter. The *STRB* signal is normally taken LOW, after *ACK* has risen.

ACK Input-Strobe Acknowledge (TTL Output)

The rising edge of *ACK* signifies that the Am7968 is ready to accept new Data and Command. The timing of *ACK's* response to *STRB* depends on the condition of the Input Latch (in a given CLK cycle) and on the Transmitter's operating mode (Local or Cascade).

In Local mode, if the Input Latch is empty, data is immediately stored and *ACK* closely follows *STRB*. If the Input Latch contains previously stored data when *STRB* is asserted, *ACK* is delayed until the next falling edge of *CLK*. Note that for *ACK* to rise *STRB* must remain HIGH for both of the above conditions.

If *STRB* is asserted when in Cascade mode, *ACK* will stay LOW until Sync is detected in the Shifter. The rising edge of *ACK* signifies that all Cascaded data has propagated downstream.

SERIN Serial Data In (ECL Input)

The *SERIN* input accepts ECL voltage swings, which are referenced to + 5.0 V. *SERIN* data passes into the internal Shifter and allows one Am7968 Transmitter to be cascaded with another. *SERIN* directly connects to another Am7968 Transmitter's *SEROUT+* output. This pin has an internal pull-down resistor and is interpreted as a logic "0" when left unconnected.

SEROUT+, SEROUT− Differential Serial Data Out (Differential Open Emitter ECL Outputs)

These differential ECL outputs generate data at ECL voltage levels referenced to + 5.0 V. When connected to appropriate pull down resistors, they are capable of driving 50-Ω terminated lines, either directly or through isolating capacitors.

X_1, X_2 Crystal Oscillator Inputs (Inputs)

These two crystal input pins connect to an oscillator which operates at the fundamental frequency of a parallel resonant crystal. The byte rate matches the crystal frequency.

Alternatively, X_1 can be driven by an external TTL frequency source. In multiple TAXI systems this external source could be another Am7968's *CLK* output.

DMS Data Mode Select (Input)

Data Mode Select input determines the Data pattern width. When it is wired to GND, the Am7968 Transmitter will assume Data to be eight bits wide, with four bits of Command. When it is wired to V_{CC}, the Am7968 Transmitter will assume Data to be nine bits wide, with three bits of Command. If *DMS* is left floating (or terminated to 1/2 V_{CC}), the Am7968 will assume Data to be ten bits wide, with two bits of Command.

CLS Cascade/Local Select (Input)

Cascade/Local Select input determines the mode of operation. When it is wired to V_{CC}, the Am7968 Transmitter is in Cascade mode and should be connected to another Am7968 Transmitter. In Cascade mode the Am7968 will output NRZ data instead of NRZI data, and will disable its *CLK* output. When *CLS* is wired to GND, the Am7968 Transmitter assumes a Local mode connection to the media. It will output NRZI encoded data, and will enable its *CLK* output driver.

When this input is left unconnected, it floats to an intermediate level which puts the Am7968 Transmitter into its test mode. In Test mode, the internal clock multiplier is switched out, and the internal logic is clocked directly from the *CLK* pin. Test mode is included to ease Automatic Test Equipment (A.T.E.) testing by making the internal logic of the TAXI synchronous to the external clock instead of the internal PLL. Cascade operation is available in commercial temperature range parts only.

CLK Clock (TTL I/O)

CLK is an I/O pin that supplies the byte-rate clock reference to drive all internal logic and to synchronize cascaded Am7968 Transmitters. When *CLS* is connected to ground (Local mode), *CLK* is enabled as a free-running (byte rate) clock output which runs at the Crystal Oscillator frequency; this output can be used to drive the X_1 input of TAXIchip Receivers or the *CLK* input of other Am7968s which are in Cascade mode. When *CLS* is connected to V_{CC} (Cascade mode), the *CLK* pin acts as an input reference for the internal PLL clock multiplier, and a synchronizing reference for cascaded Am7968 Transmitters. In Test mode *CLK* becomes a 'bit rate' input.

RESET PLL RESET (Input)

This pin is normally left open, but can be momentarily grounded to force the internal PLL to reactivate lock. This allows for correction in the unlikely occurrence of PLL lockup on application of power.

V_{CC1}, V_{CC2}, V_{CC3} Power Supply

V_{CC1}, V_{CC2} and V_{CC3} are + 5.0 volt nominal power supply pins. V_{CC1} powers TTL, V_{CC2} powers ECL and V_{CC3} powers Logic and Analog circuitry.

GND_1, GND_2 Ground Pins

GND_1 is a TTL Ground and GND_2 is Logic and Analog Ground.

Am7969 TAXIchip Receiver

$DO_0 - DO_7$ Parallel Data Out (TTL Outputs)
These eight outputs reflect the most recent valid Data received by the Am7969 Receiver.

DO_8/CO_3 Parallel Data (8) Out or Command (3) Out (TTL Output)
DO_8/CO_3 output will be either a Data or Command bit, depending upon the state of *DMS*.

DO_9/CO_2 Parallel Data (9) Out or Command (2) Out (TTL Output)
DO_9/CO_2 output will be either a Data or Command bit, depending upon the state of *DMS*.

$CO_0 - CO_1$ Parallel Command Out (TTL Output)
These two outputs reflect the most recent valid Command data received by the Am7969 Receiver.

DSTRB   Output Data Strobe (TTL Output)
The rising edge of this output signals the presence of new Data on the $DO_0 - DO_9$ lines. Data is valid just before the rising edge of *DSTRB* .

CSTRB   Command Data Strobe (TTL Output)
The rising edge of this output signals the presence of new Command data on the $CO_0 - CO_3$ lines. Command bits are valid just before the rising edge of *CSTRB.*

VLTN   Violation (TTL Output)
The rising edge of this output indicates that a transmission error has been detected. It changes state at the same time DO_i or CO_i change and will be followed by either *DSTRB* or *CSTRB*. This pin goes LOW when the next valid byte is decoded.

IGM   I-Got-Mine (TTL Output)
This pin signals cascaded Am7969 Receivers that their up-stream neighbor has captured its assigned data byte. *IGM* falls at the mid-byte point, when the first half of a sync byte is detected in the Shifter. It rises when, at the mid-byte point, it detects a non-sync pattern. During Local mode operation the *IGM* signal is undefined.

CLK   Clock (TTL Output)
This is a free-running clock output which runs at the byte rate, and is synchronous with the serial transfer rate. It falls at the time that the Decoder Latch is loaded from the Shifter, and rises at mid-byte. The *CLK* output of the Receiver is not suitable as a frequency source for another TAXI Transmitter or Receiver. It is intended to be used by the host system as a clock synchronous with the received data.

CNB   Catch Next Byte Input (TTL Input)
This input controls the Cascade mode on the Am7969 Receiver. If this input is connected to the *CLK* output, the Receiver will be in the Local mode, and each received byte will be captured, decoded and latched to the outputs.

If the *CNB* input is HIGH, it allows the Am7969 Receiver to capture the first byte after a sync. The Am7969 Receiver will wait for another sync before latching the data out, and capturing another. If *CNB* is toggled LOW, it will react as if it had decoded a sync byte.

In Cascade mode, *CNB* input is typically connected to an upstream Am7969's *IGM* output. The first Am7969 Receiver in line will have its *CNB* input connected to V_{CC}.

SERIN+, SERIN–   Differential Serial Data In (ECL Inputs)
Data is shifted serially into the Shifter. The *SERIN+* and *SERIN–* differential ECL inputs accept ECL voltage swings, which are referenced to + 5.0 V. When *Serin–* is grounded, the Am7969 is put into Test Mode; *Serin+* becomes a single-ended ECL input, the PLL clock generator is bypassed, and X_1 determines the bit rate (rather than the byte rate). Both pins have internal pull down resistors which cause unterminated inputs to stay low.

X_1, X_2 Crystal Oscillator Inputs (Inputs)
These two crystal input pins connect to an oscillator which oscillates at the fundamental frequency of a parallel resonant crystal (byte rate). Alternatively, X_1 can be driven by an external frequency source. In multiple TAXI systems, this external source could be another Transmitter's *CLK* output or an external TTL frequency source.

DMS   Data Mode Select (Input)
DMS selects the Data pattern width. When it is wired to GND, the Am7969 Receiver will assume Data to be eight bits wide, with four bits of Command. When it is wired to V_{CC}, the Am7969 Receiver will assume Data to be nine bits wide, with three bits of Command. If *DMS* is left floating (or terminated to 1/2 V_{CC}), the Am7969 Receiver will assume Data to be ten bits wide, with two bits of Command.

RESET   PLL RESET (Input)
This pin is normally left open, but can be momentarily grounded to force the internal PLL to reachieve lock to X_1. This allows for correction in the unlikely occurrence of PLL lockup on application of power.

V_{CC1}, V_{CC2} Power Supply
V_{CC1} and V_{CC2} are + 5.0 volt nominal power supply pins. V_{CC1} powers TTL, and V_{CC2} powers Logic and Analog circuitry.

GND_1, GND_2 Ground
GND_1 is a TTL Ground, GND_2 is a Logic and Analog Ground.

FUNCTIONAL DESCRIPTION

System Configuration

The TAXIchip system (see Block Diagrams and Figure 2) has two main configurations, Local mode and Cascade mode (Figures 3 & 4). In the Local mode, each Transmitter/Receiver pair is connected by a separate high-speed serial link. In the Cascade mode, one high-speed serial link is shared by several TAXI pairs.

In either mode, the Am7968 Transmitter accepts inputs from a sending host system using a simple *STRB/ACK* handshake. Parallel bits are saved by the Am7968's input latch on the rising edge of a *STRB* input. The input latch can be updated on every *CLK* cycle; if it still contains previously stored data when a second *STRB* pulse arrives, Data is stored in the input latch, delaying the second *ACK* response until the next *CLK* cycle.

The inputs to an Am7968 Transmitter can be either Data or Command and may originate from two different parts of the host system. A byte cycle may contain Data or Command, but not both. Data represents the normal data channel message traffic between host systems. Commands can come from a communication control section of the host system. Commands

7

occur at a relatively infrequent rate but have priority over Data. Examples include communication specific commands such as REQUEST-TO-SEND or CLEAR-TO-SEND; or application specific commands such as MESSAGE-ADDRESS-FOLLOWS, MESSAGE-TYPE-FOLLOWS, INITIALIZE YOUR SYSTEM, ERROR, RETRANSMIT, HALT, etc.

The Am7968 Transmitter switches between Data and Command by examining Command input patterns. All 0's on Command input pins cause information on the Am7968's Data input pins to be latched into the device on the rising edge of STRB. All other Command patterns cause a Command symbol to be sent in response to an input strobe. The pattern on the Data inputs is ignored when a Command symbol is sent. In either case, if there is no STRB before the next byte boundary, a Sync symbol will be transmitted. The Sync pattern maintains link synchronism and provides an adequate signal transition density to keep the Receiver Phase-Locked-Loop (PLL) circuits in lock. It was chosen for its unique pattern which never occurs in any Data or Command messages. This feature allows Sync to be used to establish byte boundaries.

The Sync pattern utilized by TAXIchips keeps the automatic gain control (AGC) fiber-optic transceiver circuits in their normal range because the pattern has zero DC offset.

The Am7969 Receiver detects the difference between Data and Command patterns and routes each to the proper Output Latch. When a new Data pattern is captured by the output latch, DSTRB is pulsed and Command information remains unchanged. If a Command pattern is sent to the output latch or if Sync is received, CSTRB is pulsed and Data outputs remain in their previous state. Reception of a Sync pattern clears the Command outputs to all 0's, since Sync is a legal command.

Noise-induced bit errors can distort transmitted bit patterns. The Am7969 Receiver logic detects most noise-induced transmission errors. Invalid bit patterns are recognized and indicated by the assertion of the violation (VLTN) output pin. This signal rises to a logic "1" state at the same time that Data or Command outputs change and remains HIGH until a valid pattern is detected by the Data Decoder. The error detection method used in the Receiver cannot identify bit errors which transform one valid Command or Data pattern to another. Fault-sensitive systems should use additional error checking mechanisms to guarantee message integrity.

Am7968 Transmitter

The Transmitter can accept messages from either of two sources: parallel input pins (Command or Data) or the SERIN input. The device will send data which appears on its SERIN pin only if there is no new parallel information to be sent (evident by lack of strobe). This single-ended ECL input is intended to be left open or connected to the SEROUT+ pin of another TAXI Transmitter (see Cascade Mode). Once latched into an Am7968, a parallel message is encoded, serialized, and shifted out to the serial link. The idle time between transmitted bytes is filled with Sync bytes.

Am7969 Receiver

Receivers accept differential signals on the SERIN+ /SERIN– input pins. This information, previously encoded by an Am7968 Transmitter, is loaded into a decoder.

When serial patterns are received, they are decoded and routed to the appropriate outputs. If the received message is a Command, it is stored in the output latch, appears at the Command output pins, and CSTRB is pulsed; Data output pins continue holding the last Data byte and DSTRB stays inactive. If a Data message follows the reception of a Command, Command output pins continue holding the previous Command byte and CSTRB stays inactive. The command outputs

will retain their states until another Command signal is received (Sync is considered to be a valid command which, when decoded, sets Command outputs to "0" and issues a resulting CSTRB).

Byte Width

TAXIchips have twelve parallel interface pins which are designated to carry either Command or Data bits. The Data Mode Select (DMS) pin on each chip can be set to select one of three modes of operation: eight Data and four Command bits, nine Data and three Command, or ten Data and two Command. This allows the system designer to select the byte-width which best suits system needs.

Am7968 Encoder/Am7969 Decoder

To guarantee that the Am7969's PLL can stay locked onto an incoming bit stream, the data encoding scheme must provide an adequate number of transitions in each data pattern. This implies a limit on the maximum time allowed between transitions. The TAXIchip encoding scheme is based on the ANSI X3T9.5 (FDDI) committee's 4-bit/5-bit (4B/5B) code.

An ANSI X3T9.5 system uses an 8-bit parallel data pattern. This pattern is divided into two 4-bit nibbles which are each encoded into a 5-bit symbol. Of the thirty-two patterns possible with these five bits, sixteen are chosen to represent the sixteen input Data patterns. Some of the others are used as Command symbols. Those remaining represent invalid patterns that fail either the run-length test or DC balance tests.

Transmitters in 8-bit mode use two 4B/5B encoders to encode eight Data bits into a 10-bit pattern. In 9-bit mode, Transmitters use one 5B/6B encoder and one 4B/5B encoder to code nine Data bits into an 11-bit pattern. In 10-bit mode, two 5B/6B encoders are used to change ten bits of Data into a 12-bit pattern. (See Tables 1 and 2 for encoding patterns.)

The Am7968 Transmitter further encodes all symbols using NRZI (Non Return to Zero, Invert on ones). NRZI represents a "1" by a transition and a "0" by the lack of a transition. In this system a "1" can be a HIGH-to-LOW or LOW-to-HIGH transition. This combination of 4B/5B and NRZI encoding ensures at least two transitions per symbol and permits a maximum of three consecutive non-transition bit times. The Am7969 then uses the same method to decode incoming symbols so that the whole encoding/decoding process is transparent to the user.

Serially transmitted data patterns with this code will have the same average amount of HIGH and LOW times. This DC balance minimizes pattern-sensitive decoding errors which are caused by jitter in AC-coupled systems.

Operational Modes

Local Mode

In this mode, a single Transmitter/Receiver pair is used to transfer 8, 9, or 10 bits of parallel Data over a private serial link. On the Am7968, CLS is tied to ground and SERIN is left open. The Am7969 Receiver continuously deserializes the incoming bit stream, decodes the resulting patterns, and saves parallel data at its output latches (see Figure 3).

Local mode provides the fastest potential parallel throughput because data can be transferred on every clock cycle. On the other hand, it is not necessary for the host to match the byte rate set by the Transmitter's crystal oscillator; the Am7968 automatically sends a Sync pattern during each clock cycle in which no new Data or Command messages are being transmitted.

During Local mode operation, the IGM signal is undefined.

Cascade Mode

For very wide parallel buses, TAXI's (commercial temperature parts only) can be Cascaded to send multiple-byte words over a single serial channel (see Figure 4). The primary Transmitter has its SEROUT± pins tied to the media (or an optical data link) and its SERIN pin is connected to the SEROUT+ pin of its upstream neighbor. This SERIN–/SEROUT+ connection is repeated for each subsequent Am7968 in the chain. CLS on the primary Transmitter is tied to ground, putting it in Local mode, and is connected to V_{CC} on all other Am7968s in the chain, putting them in Cascade mode. The DMS pin must be tied to the same level on every TAXI, putting each of them in the same bit configuration (8 –, 9 –, or 10-bit mode). The CLK output of the primary Transmitter is tied to the CLK input pin of each upstream Am7968. The Am7969 Receivers all have their SERIN+ and SERIN– pins connected to the media (or an optical data link). IGM of each Am7969 is connected to CNB of its downstream neighbor or is left unconnected on the Receiver farthest downstream. CNB of the first Receiver is tied HIGH, making this device the only Receiver in the chain that can act on the first non-Sync pattern in a message (see below).

In a Cascaded system, all Transmitters simultaneously latch their message upon seeing a common STRB. Cascaded Transmitters must place at least one Sync between words. This is easily accomplished by using the ACK response from the Am7968 second from the media as a "ready" indication.

Each TAXIchip Receiver monitors the serial link and a special acknowledgement scheme is used to direct symbols into each of the Am7969s. When a Catch-Next-Byte (CNB) input is HIGH, the Receiver will capture the next non-Sync symbol from the serial link. At this point, the device forces its I-Got -Mine (IGM) pin HIGH to tell the downstream Receiver to capture the next symbol. The Receiver then waits for the Sync symbol or for its CNB to be set LOW before transferring the message to its output latch. IGM is forced LOW whenever a Sync byte is detected or when CNB goes LOW. This IGM-CNB exchange continues down the chain until the last Receiver captures its respective byte. The next byte to appear on the serial link will be a Sync symbol which is detected by all of the cascaded Am7969s. On the following Clock cycle their messages are transferred to the output latch of each device and sent to the receiving host. IGM pins on all Receivers are also set LOW when the first half of the Sync symbol is detected.

Unbalanced Cascade Operation

While Local and Cascade modes require an equal number of Receivers and Transmitters used in a link to be equal. Unbalanced operation allows unequal combinations of Transmitters and Receivers to be Cascaded;
e.g., 2 Transmitters to 4 Receivers or
   4 Transmitters to 1 Receiver, etc.

Asynchronous Operation

In Local mode, inputs to the Am7968 Transmitter Input Latch can be asynchronous to its internal clock. Data STRB will latch data into the Am7968 Transmitter and an internal clock will transfer the data to the Encoder Latch at the first byte boundary. Data can be entered at any rate less than the maximum transfer rate without regard to actual byte boundaries. Individual data events can be strobed into the Am7968 Transmitter at less than the byte transfer time, if the STRB/ ACK protocol is observed.

In systems where Am7969 Receivers lose byte/symbol sync, and on power-up, internal logic detects this loss-re-acquisition of sync and modifies the CLK output. CLK output is actually a buffered version of the signal which controls Data transfers inside the Am7969 Receiver on byte boundaries. Byte boundaries move when the Am7969 Receiver loses, and re-acquires sync. To protect slave systems (which may use this output as a master clock) from having clocks which are too narrow, the output logic will stretch an output when the output pulse would have been less than a byte-time long. The data being processed just prior to this re-acquisition of sync will be lost. The Sync symbol, and all subsequent data will be processed correctly.

TAXI User Test Modes

Cascade/Local Select (CLS) input can be used to force the Am7968 Transmitter into a Test mode. This will allow testing of the logic in the Latches, Encoder, and Shifter without having to first stabilize the PLL clock multiplier. If CLS is open or terminated to approximately $V_{CC}/2$, the internal V_{CO} is switched out and everything is clocked directly from the CLK input. This means that the serial output data rate will be at the byte Clock rate and not at 10X, 11X, or 12X, as is the case in normal operation.

Differential SERIN+ /SERIN– inputs can be used to force the Am7969 Receiver into a Test mode. This will allow testing of the logic in the Latches, Decoder, and Shifter without having to first stabilize the PLLs. If SERIN– is tied to ground, the internal V_{CO} is switched out and X_1 becomes the internal bit rate clock. This means that the serial data rate will be at the crystal rate, not at 10X, 11X, or 12X, as is the case in normal operation. In this mode, SERIN+ becomes a single-ended serial data input with nominal 100K ECL threshold voltages (Referenced to + 5 volts).

These switches make the parts determinate, synchronous systems, instead of statistical, asynchronous ones. An automatic test system will be able to clock each part through the functional test patterns at any rate or sequence that is convenient. After the logic has been verified, the part can be put back into the normal mode, and the PLL functions verified knowing that the rest of the chip is functional.

Oscillator

The Am7968 and Am7969 contain an inverting amplifier intended to form the basis of a parallel mode oscillator. In designing this oscillator, it is necessary to consider several factors related to the application.

The first consideration is the desired frequency accuracy. This may be subdivided into several areas. An oscillator is considered stable if it is insensitive to variations in temperature and supply voltage, and if it is unaffected by individual component changes and aging. The design of the TAXIchips is such that the degree to which these goals are met is determined primarily by the choice of external components. Various types of crystals are available and the manufacturers' literature should be consulted to determine the appropriate type. For good temperature stability, zero temperature coefficient capacitors should be used (Type NPO).

The mechanism by which a crystal resonates is electromechanical. This resonance occurs at a fundamental frequency (1st harmonic) and at all odd harmonics of this frequency (even harmonic resonance is not mechanically possible). Unless otherwise constrained, crystal oscillators operate at their fundamental frequency.

A typical crystal specification for use in this circuit is:

Fundamental Frequency:	4 – 12.5 MHz ± 0.1%
Resonance: Mode	Parallel
Load Capacitor (Correlation)	75 pF
Operating Temperature Range	0 to 70°C
Temperature Stability	±100 ppm
Drive Level (Correlation)	2 mW
Effective Series Resistance	25 Ω (max)
Holder: Type	Low profile
Aging for 10 years	±10 ppm

It is good practice to ground the case of the crystal to eliminate stray pick-up and keep all connections as short as possible.
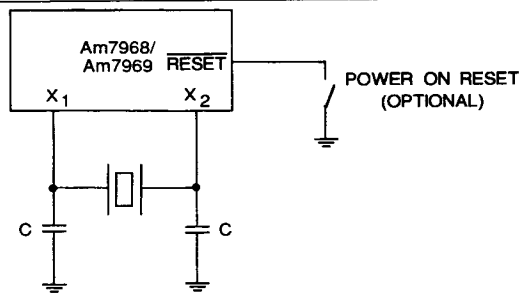

C* = 150 pF for a 12.5-MHz Crystal,
      220 pF for a 4-MHz Crystal.
*C determined by crystal specifications and trace capacitances. Values shown are typical.

Figure 1. Connections for 4-12.5 MHz

TABLE 1. TAXIchip ENCODER PATTERNS

			1D	11101	111011
			1E	11110	111100
			1F	11111	111101

*Note: HEX data is parallel input data which is represented by the 4- or 5-bit binary data listed in the column to the immediate right of HEX data. Binary bits are listed from left to right in the following order:

8-Bit Mode: D_7, D_6, D_5, D_4 (4-Bit Binary), and D_3, D_2, D_1, D_0 (4-Bit Binary)
9-Bit Mode: D_8, D_7, D_6, D_5, D_4 (5-Bit Binary), and D_3, D_2, D_1, D_0 (4-Bit Binary)
10-Bit Mode: D_8, D_7, D_6, D_5, D_4 (5-Bit Binary), and D_9, D_3, D_2, D_1, D_0 (5-Bit Binary)

Serial bits are shifted out with the most significant bit of the most significant nibble coming out first.

Notes:
1. Command pattern Sync cannot be explicitly sent by Am7968 Transmitter with any combination of inputs and *STRB*, but is used to pad between user data.
2. These commands will disrupt Cascade Am7968 Transmitters and should be used only in Local mode.
3. A strobe with all 0s on the Command input lines will cause Data to be sent. See Table 1.
4. While these commands are legal data and will not disrupt normal operation if used occasionally, they may cause data errors if grouped into recurrent fields. Normal PLL operation cannot be guaranteed if one or more of these commands is continuously repeated.

Am7968 Transmitter Functional Block Description
(Refer to page 1)

Crystal Oscillator/Clock Generator

The serial link speed is derived from a master frequency source (byte rate). This source can either be the built-in Crystal Oscillator, or a clock signal applied through the X_1 pin. This signal is buffered and sent to the CLK output when Am7968 Transmitter is in Local mode.

In Cascade mode, the Am7968 Transmitter CLK pin becomes an input and is always taken from the CLK output of the Am7968 that is farthest "downstream" and is in Local mode.

CLK input is multiplied by ten (8-bit mode), eleven (9-bit mode), or twelve (10-bit mode), using the internal PLL to create the bit rate.

The working frequency can be varied over a three-to-one range. The crystal frequency required to achieve the maximum 125 Mbaud on the serial link, and the resultant usable data transfer rate will be:

Mode	Crystal Frequency	Am7968 Input and Am7969 Maximum Parallel Throughput	Internal Divide Ratio
8-Bit	12.50 MHz	80 ns/pattern (100 Mbit/sec)	125/10
9-Bit	11.36 MHz	88 ns/pattern (102 Mbit/sec)	125/11
10-Bit	10.42 MHz	96 ns/pattern (104 Mbit/sec)	125/12

Input Latch

The Am7968's Input Latch accommodates asynchronous strobing of Data and Command by being divided into two stages.

If STRB is asserted when both stages are empty, Data or Command bits are transferred directly to the second stage of the Input Latch and ACK rises shortly after STRB. This pattern is now ready to move to the Encoder Latch at the next falling edge of CLK.

An input pattern is strobed into the first stage of the Input Latch only when the second stage is BUSY (contains previously stored data). The Transmitter will be BUSY when STRB is asserted a second time in a given CLK cycle. Contents of the first stage are not protected from subsequent STRBs within the same CLK cycle. At the falling edge of CLK, previously stored data is transferred from the second stage to the Encoder Latch and the new data is clocked into the

second stage of the Input Latch. If in Local mode, ACK will rise at this time.

Encoder Latch

Input to the Encoder Latch is clocked by an internal signal which is synchronous with the shifted byte being sent on the serial link. Whenever a new input pattern is strobed into the Input Latch, the data is transferred to the Encoder Latch at the next opportunity.

Data Encoder

Encodes twelve data inputs (8, 9, 10 Data bits or 4, 3, 2 Command inputs) into 10, 11, or 12 bits. The Command data inputs control the transmitted symbol. If all Command inputs are LOW, the symbol for the Data bits will be sent. If Command inputs have any other pattern then the symbol representing that Command will be transmitted.

Shifter

The Shifter is parallel loaded from the Encoder at the first available byte boundary, and then shifted until the next byte boundary. The Shifter is being serially loaded at all times. As data is being shifted out of the TAXI, the shifter fills from the LSB. If parallel data is available at the end of the byte, it is parallel-loaded into the Shifter and begins shifting out during the next clock cycle. Otherwise, the serially loaded data fills the next byte. The serial data which is loaded into the Shifter will come from one of two sources:

1. If the Am7968 Transmitter is receiving valid data at its SERIN input, then the serial data will come from the external serial input.

2. If the Am7968 Transmitter is not receiving valid data (good data never has five consecutive 0s), then the serial data will be generated by an internal state machine which generates a repeating Sync pattern.

Serial Interface

The Serial Interface is a level-restoring buffer in Cascade mode. In Local mode it generates the Sync symbol to pad the spaces between user-data patterns.

Media Interface

The Media Interface is differential ECL, referenced to +5 V. It is capable of driving lines terminated with 50 Ohms to $(V_{CC} - 2.0)$ Volts.

Am7969 Receiver Functional Block Description
(Refer to page 1)

Crystal Oscillator/Clock Generator

The data recovery PLL in the AM7969 must be supplied with a reference frequency at the expected byte rate of the data to be recovered. The source of this frequency can either be the built-in Crystal Oscillator, or an external clock signal applied through the X_1 pin. The reference frequency source is then multiplied by ten (8-bit mode), eleven (9-bit mode) or twelve (10-bit mode) using an internal PLL.

Media Interface

SERIN+, SERIN– inputs are to be driven by differential ECL voltages, referenced to +5 V. Serial data at these inputs will serve as a reference for PLL tracking.

PLL Clock Generator

A PLL Clock recovery loop follows the incoming data and allows the encoded clock and data stream to be decoded into a separated clock and data pattern. It uses the crystal

oscillator and clock generator to predict the expected frequency of data and will track jittered data with a characteristically small offset frequency.

Shifter

The Shifter is serially loaded from the Media Interface, using the bit clock generated by PLL.

Byte Sync Logic

The incoming data stream is a continuous stream of data bits, without any significant signal which denotes byte boundaries. This logic will continuously monitor the data stream, and upon discovering the reserved code used for Am7969 Receiver Sync, initialize a synchronous counter which counts bits, and indicates byte boundaries.

The logic signal that times data transfers from the Shifter to the Decoder Latch is buffered and sent to the CLK output. CLK output from the Receiver is not suitable for a frequency

source of another TAXI Transmitter or Receiver. It is intended to be used by the host system as a clock synchronous with the received data. This output is synchronous with the byte boundary and is synchronous with the Receivers's internal byte clock.

Byte Sync Logic is responsible for generating the internal strobe signals for Parallel Output Latches. It also generates the *IGM* (I-Got-Mine) signal in Cascade mode when the first byte after a Sync symbol is transferred. Parallel outputs are made on a byte boundary, after *CNB* falls, or when Sync is detected.

The I-Got-Mine (*IGM*) signal will fall when the first half of a Sync is detected in the Shifter or when *CNB* goes LOW. It will remain LOW until the first half of a non-Sync byte is detected in the Shifter, whereupon it will rise (assuming that the *CNB* input is HIGH). A continuous stream of normal data or command bytes will cause *IGM* to go HIGH and remain HIGH. A continuous stream of Sync's will cause *IGM* to stay LOW. *IGM* will go HIGH during the byte before data appears at the output. This feature could be used to generate an early warning of incoming data.

Decoder Latch

Data is loaded from the Shifter to this latch at each symbol/byte boundary. It serves as the input to the Data Decoder.

Data Decoder

Decodes ten, eleven or twelve data inputs into twelve outputs. In 8-bit mode, data is decoded into either an 8-bit Data pattern or a 4-bit Command pattern. In 9-bit mode, data is decoded into either a 9-bit Data pattern or a 3-bit Command pattern. In 10-bit mode, data is decoded into either a 10-bit Data pattern or a 2-bit Command pattern.

The decoder separates Data symbols from Command symbols, and causes the appropriate strobe output to be asserted.

Parallel Output Latch

Output Latch will be clocked by the byte clock, and will reflect the most recent data on the link. Any Data pattern will be latched to the Data outputs and will not affect the status of the Command outputs. Likewise, any Command pattern will be latched to the Command outputs without affecting the state of the Data outputs.

Any data transfer, either Data or Command will be synchronous with an appropriate output strobe. However, there will be *CSTRBs* when there is no active data on the link, since sync is a valid Command code.

Any pattern which does not decode to a valid Command or Data pattern is flagged as a violation. The output of the decoder during these violations is indeterminate and will result in either a *CSTRB* or *DSTRB* output when the indeterminate pattern is transferred to the output latch.

ABSOLUTE MAXIMUM RATINGS

Storage Temperature .... −65 to +150°C
Ambient Temperature Under Bias .... −55 to +125°C
Supply Voltage to Ground
    Potential Continuous .... −0.5 to +7.0 V
DC Voltage Applied to Outputs .... −0.5 V to V_{CC} Max.
DC Input Voltage .... −0.5 to +5.5 V
DC Output Current .... ±100 mA
DC Input Current .... −30 to +5.0 mA

Stresses above those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent device failure. Functionality at or above these limits is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

OPERATING RANGES

Commercial (C) Devices
    Temperature (T_A) .... 0 to +70°C
    Supply Voltage (V_{CC}) .... +4.5 to +5.5 V

Military (M) Devices
    Temperature (T_C) .... −55 to +125°C
    Supply Voltage (V_{CC}) .... +4.5 to +5.5 V

Operating ranges define those limits between which the functionality of the device is guaranteed.

DC CHARACTERISTICS over operating range unless otherwise specified (for APL Products, Group A, Subgroups 1, 2, 3 are tested unless otherwise noted)

53	t_F	CLK Fall Time (Note 3)			10	ns
Serial Interface Signals: SERIN+, SERIN–						
57	t_J	SERIN± Peak to Peak Input Jitter Tolerance (Note 16)			5	ns
Miscellaneous: X_1 (Note 15)						
60	t_{PW}	X_1 Pulse Width HIGH		35		ns
61	t_{PW}	X_1 Pulse Width LOW		35		ns

Notes: See notes following Switching Characteristics tables.

Notes:* 1. For conditions shown as Min. or Max, use the appropriate value specified under operating range.
2. Typical limits are at $V_{CC} = 5.0$ V, 25°C ambient and maximum loading.
3. Rise and Fall time measurements are made at 20% and 80% points.
4. Not more than one output should be shorted at a time. Duration of the short circuit test should not exceed one second.
5. If the CNB ↑ to CLK ↑ setup time is violated, IGM will stay LOW.
6. Voltage applied to either SERIN± pins must not be above V_{CC} nor below +2.5 V to assure proper operation.
7. t_4 guarantees that data is latched. ACK (t_{11}) timing may not be valid.
8. If t_{11} is not met, ACK response and timing are not guaranteed, but data will still be latched on STRB ↑ (see t_4).
9. Measured with device in Test mode while monitoring output logic states.
10. For the TAXI Transmitter, 'n' is determined by the state of DMS and CLS inputs. When CLS is open, n = 1. When CLS is either HIGH or LOW and when:
   DMS is LOW, n = 10 (8 Bit mode),
   DMS is HIGH, n = 11 (9 Bit mode),
   DMS is OPEN, n = 12 (10 Bit mode).
11. t_6 (Internal Byte Boundary to CLK ↓) is created by the variation of internal STRB propagation delays relative to internal byte boundaries over temperature and V_{CC}. The internal byte boundary determines the byte in which data will come out (at SEROUT±). If STRB occurs before the byte boundary, then the data will be sent out two bytes later. If STRB occurs after the byte boundary, then the output data will be delayed by one additional byte.
12. X_1 Pulse Width is measured at a point where CLK output exactly meets CLK input (t_2 or t_3) spec limit.
13. For the TAXI Transmitter, 'Data' is either $DI_0 - DI_7$, DI_8/Cl_3, DI_9/Cl_2, $Cl_0 - Cl_1$. For the TAXI Receiver, 'STRB' is either CSTRB or DSTRB and 'Data' is either $DO_0 - DO_7$, DO_8/CO_3, DO_9/CO_2, $CO_0 - CO_1$.
14. For the TAXI Receiver, 'n' is determined by the state of the DMS and SERIN– inputs. When SERIN– is held below V_{THT} min or left open, n = 1. When SERIN– is held above V_{THT} max, and when:
   DMS is LOW, n = 10 (8 Bit mode),
   DMS is HIGH, n = 11 (9 Bit mode),
   DMS is OPEN, n = 12 (10 Bit mode).
15. Jitter on X_1 input must be less than ±0.2 ns.
16. This specification applies to any edge of an incoming pattern.
18. ACK delay is determined by t_{13} when the input latch is empty or by t_{15A} when the input latch is full (Busy mode). In the Cascade mode, ACK delay is determined by t_{15B}. Also note that ACK will not rise if STRB does not remain HIGH until ACK rises.
19. If t_{47A} (CNB ↓ to CLK ↑ setup) is violated, then output data will occur one byte time later.
20. All timing references are made with respect to +1.5 V for TTL-level signals or to the 50% point between V_{OH} and V_{OL} for ECL signals. ECL input rise and fall times must be 2 ns ± 0.2 ns between 20% and 80% points. TTL input rise and fall times must be 2 ns between 1 V and 2 V.
21. Device thresholds on the SERIN (+/–) pin(s) are verified during production test by ensuring that the input threshold is less than V_{IHS} (min) and greater than V_{ILS} (max). The figure below shows the acceptable range (shaded area) for the transition voltage.

		---	V_{CC}
V_{IHS}	(max)	---	$V_{CC} - 0.88$ V
	(min)	---	$V_{CC} - 1.165$ V
		/ /	
		/ /	Input threshold
		/ /	transition voltage.
		/ /	
V_{ILS}	(max)	---	$V_{CC} - 1.475$ V
	(min)	---	$V_{CC} - 1.81$ V

22. t_{15A} specifies CLK ↓ to ACK ↑ in BUSY (Local) mode.
   t_{15B} specifies CLK ↓ to ACK ↑ in Cascade mode.
23. Cascaded Transmitters should have V_{CC} within 0.2 V and temperature within 10°C of each other.

† Not included in group A tests.

* Notes listed correspond to the respective references made in the DC characteristics and the Switching characteristics tables.
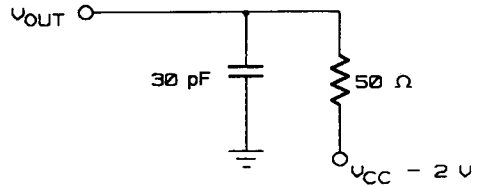

SWITCHING TEST CIRCUITS

TTL Output Load
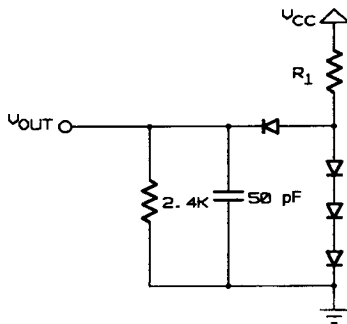

TC002820

Notes: 1. $R_1 = 500\ \Omega$ for the $I_{OL} = 8$ mA
2. All diodes IN916 or IN3064, or equivalent
3. $C_L = 50$ pF includes scope probe, wiring and stray capacitances without device in test fixture.
4. AMD uses constant current (A.T.E.) load configurations and forcing functions. This figure is for reference only.
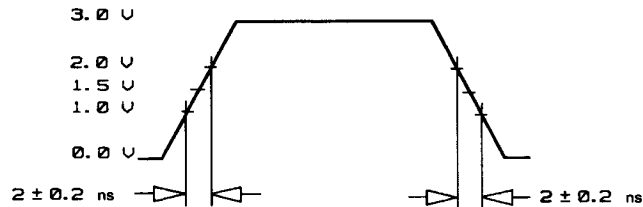

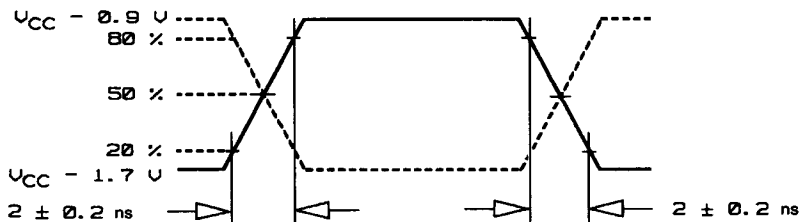

ECL Output Load

TC002831

Notes: 1. $C_L = 30$ pF includes scope probe, wiring and stray capacitances without device in text fixture.
2. AMD uses Automatic test equipment load configurations and forcing functions. This figure is for reference only.

*Internal Signals

Notes:
1. Sync detected in Shifter, but not synchronized with internal state machine.
2. State machine re-synched to new sync position.
3. CLK output delayed to new position.
4. CLK LOW or HIGH time gets stretched depending on what states of the internal machine are skipped.
5. IGM rises at the 65th state of the state machine.
6. STRB falls at the rising edge of the CLK Out.
7. STRB may be shifted one bit time if the state machine is reset at state 1.
