## 64K x 32 Synchronous 3.3V Cache RAM

### Features

- Supports 66-MHz microprocessor cache systems with zero wait states
- 64K by 32 common I/O
- Low Standby Power (1.65 mW, L version)
- Fast clock-to-output times  
— 9.0 ns (66-MHz version)
- Two-bit wrap-around counter supporting either interleaved or linear burst sequence
- Separate processor and controller address strobes provides direct interface with the processor and external cache controller
- Synchronous self-timed write
- Asynchronous output enable
- 3.3V I/Os
- JEDEC-standard pinout
- 100-pin TQFP packaging
- ZZ "sleep" mode

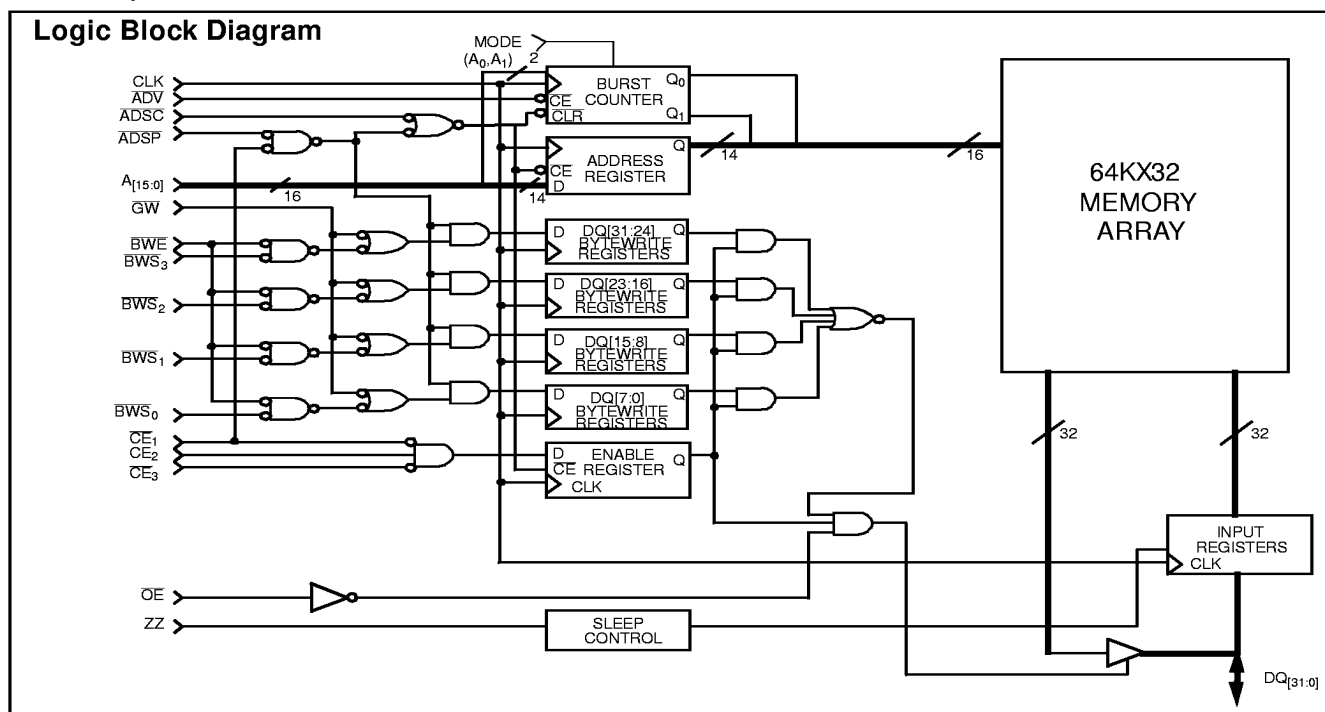

### Functional Description

The CY7C1336 is a 3.3V 64K by 32 synchronous cache RAM designed to interface with high-speed microprocessors with minimum glue logic. Maximum access delay from clock rise is 9.0 ns (66-MHz version). A 2-bit on-chip counter captures the first address in a burst and increments the address automatically for the rest of the burst access.

The CY7C1336 allows both an interleaved or linear burst sequences, selected by the MODE input pin. A HIGH selects an interleaved burst sequence, while a LOW selects a linear burst sequence. Burst accesses can be initiated with the processor address strobe (ADSP) or the cache controller address strobe (ADSC) inputs. Address advancement is controlled by the address advancement (ADV) input.

A synchronous self-timed write mechanism is provided to simplify the write interface. A synchronous chip enable input and an asynchronous output enable input provide easy control for bank selection and output three-state control.

CY7C1336

## 100-Lead TQFP

## Functional Description (continued)

### Single Write Accesses Initiated by ADSP

This access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are all asserted active, and (2) ADSP is asserted LOW. The addresses presented are loaded into the address register and the burst counter/control logic and delivered to the RAM core. The write inputs (GW, BWE, and  $BWS_{[3:0]}$ ) are ignored during this first clock cycle. If the write inputs are asserted active (see write table for appropriate states that indicate a write) on the next clock rise, the appropriate data will be latched and written into the device. Byte writes are allowed. During byte writes,  $BWS_0$  controls  $DQ_{[7:0]}$ ,  $BWS_1$  controls  $DQ_{[15:8]}$ ,  $BWS_2$  controls  $DQ_{[23:16]}$ , and  $BWS_3$  controls  $DQ_{[31:24]}$ . All I/Os are three-stated during a byte write. Since these are common I/O device, the asynchronous OE input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to  $DQ_{[31:0]}$ . As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of OE.

### Single Write Accesses Initiated by ADSC

This write access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are all asserted active, (2) ADSC is asserted LOW, (3) ADSP is deasserted HIGH, and (4) The write input signals (GW, BWE, and  $BWS_{[3:0]}$ ) indicate a write access. ADSC is ignored if ADSP is active LOW.

The addresses presented are loaded into the address register, burst counter/control logic and delivered to the RAM core. The information presented to  $DQ_{[31:0]}$  will be written into the specified address location. Byte writes are allowed. During byte writes,  $BWS_0$  controls  $DQ_{[7:0]}$ ,  $BWS_1$  controls  $DQ_{[15:8]}$ ,  $BWS_2$  controls  $DQ_{[23:16]}$ , and  $BWS_3$  controls  $DQ_{[31:24]}$ . All I/Os are three-stated when a write is detected, even a byte write. Since these are common I/O device, the asynchronous OE input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to  $DQ_{[31:0]}$ . As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of OE.

### Single Read Accesses

A single read access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are all asserted active, and (2) ADSP or ADSC is asserted LOW (if the access is initiated by ADSC, the write inputs must be deasserted during this first cycle). The address presented to the address inputs is latched into the Address Register, burst counter/control logic and presented to the memory core. If the OE input is asserted LOW, the requested data will be available at

the data outputs a maximum to  $T_{CDV}$  after clock rise. ADSP is ignored if  $\overline{CE}_1$  is HIGH.

## Burst Sequences

The CY7C1336 provides an on-chip 2-bit wrap around burst counter inside the SRAM. The burst counter is fed by  $A_{[1:0]}$ , and can follow either a linear or interleaved burst order. The burst order is determined by the state of the MODE input. A LOW on MODE will select a linear burst sequence. A HIGH on MODE will select an interleaved burst order. Leaving MODE unconnected will cause the device to default to a interleaved burst sequence.

01	10	11	00
10	11	00	01
11	00	01	10

## Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ HIGH places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode.  $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ , ADSP, and ADSC must remain inactive for the duration of  $t_{ZZREC}$  after the ZZ input returns low. Leaving ZZ unconnected defaults the device into an active state.

WRITE Cycle, Suspend Burst	Current	H	X	X	L	X	H	H	L	X	L-H	D

**Notes:**

1. X=Don't Care, 1=Logic HIGH, 0=Logic LOW.
2. The SRAM always initiates a read cycle when ADSP asserted, regardless of the state of GW, BWE, or BWS<sub>[3:0]</sub>. Writes may occur only on subsequent clocks after the ADSP or with the assertion of ADSC. As a result, OE must be driven HIGH prior to the start of the write cycle to allow the outputs to three-state. OE is a don't care for the remainder of the write cycle.
3. OE is asynchronous and is not sampled with the clock rise. During a read cycle DQ=HIGH-Z when OE is inactive, and DQ=data when OE is active

**Pin Descriptions**

TQFP Pin Number	Name	I/O	Description
85	ADSC	Input-Synchronous	Address Strobe from Controller, sampled on the rising edge of CLK. When asserted LOW, A <sub>[15:0]</sub> is captured in the address registers. A <sub>[1:0]</sub> are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized.
84	ADSP	Input-Synchronous	Address Strobe from Processor, sampled on the rising edge of CLK. When asserted LOW, A <sub>[15:0]</sub> is captured in the address registers. A <sub>[1:0]</sub> are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized. ADSP is ignored when CE <sub>1</sub> is deasserted HIGH.
36, 37	A <sub>[1:0]</sub>	Input-Synchronous	A <sub>1</sub> , A <sub>0</sub> address inputs. These inputs feed the on-chip burst counter as the LSBs as well as being used to access a particular memory location in the memory array.
49–44, 81–82, 99–100, 32–35	A <sub>[15:2]</sub>	Input-Synchronous	Address Inputs used in conjunction with A <sub>[1:0]</sub> to select one of the 64K address locations. Sampled at the rising edge of the CLK, if CE <sub>1</sub> , CE <sub>2</sub> , and CE <sub>3</sub> are sampled active, and ADSP or ADSC is active LOW.

## Pin Descriptions (continued)

TQFP Pin Number	Name	I/O	Description
96–93	BWS <sub>[3:0]</sub>	Input-Synchronous	Byte Write Select Inputs, active LOW. Qualified with BWE to conduct byte writes. Sampled on the rising edge. BWS <sub>0</sub> controls DQ <sub>[7:0]</sub> , BWS <sub>1</sub> controls DQ <sub>[15:8]</sub> , BWS <sub>2</sub> controls DQ <sub>[23:16]</sub> , BWS <sub>3</sub> controls DQ <sub>[31:24]</sub> . See write table for further details.
83	ADV	Input-Synchronous	Advance input used to advance the on-chip address counter. When LOW the internal burst counter is advanced in a burst sequence. The burst sequence is selected using the MODE input.
87	BWE	Input-Synchronous	Byte Write Enable Input, active LOW. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write.
88	GW	Input-Synchronous	Global Write Input, active LOW. Sampled on the rising edge of CLK. This signal is used to conduct a global write, independent of the state of BWE and BWS <sub>[3:0]</sub> . Global writes override byte writes.
89	CLK	Input-Clock	Clock input. Used to capture all synchronous inputs to the device.
98	CE <sub>1</sub>	Input-Synchronous	Chip Enable 1 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with CE <sub>2</sub> and CE <sub>3</sub> , to select/deselect the device. CE <sub>1</sub> gates ADSP.
97	CE <sub>2</sub>	Input-Synchronous	Chip Enable 2 Input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>3</sub> to select/deselect the device.
92	CE <sub>3</sub>	Input-Synchronous	Chip Enable 3 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>2</sub> to select/deselect the device.
86	OE	Input-Asynchronous	Output Enable, asynchronous input, active LOW. Controls the direction of the I/O pins. When LOW, the I/O pins behave as outputs. When deasserted HIGH, I/O pins are three-stated, and act as input data pins.
64	ZZ	Input-Asynchronous	Snooze input. Active HIGH asynchronous. When HIGH, the device enters a low power standby mode in which all other inputs are ignored, but the data in the memory array is maintained. Leaving ZZ floating or NC will default the device into an active state.
31	MODE	-	Mode input. Selects the burst order of the device. Tied HIGH selects the interleaved burst order. Pulled LOW selects the linear burst order. When left floating or NC, defaults to interleaved burst order.
29–28, 25–22, 19–18, 13–12, 9–6, 3–2, 79–78, 75–72, 69–68, 63–62, 59–56, 53–52	DQ <sub>[31:0]</sub>	I/O-Synchronous	Bidirectional Data I/O lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by A <sub>[15:0]</sub> during the previous clock rise of the read cycle. The direction of the pins is controlled by OE in conjunction with the internal control logic. When OE is asserted LOW, the pins behave as outputs. When HIGH, DQ <sub>[31:0]</sub> are placed in a three-state condition. The outputs are automatically three-stated when a WRITE cycle is detected.
15, 41, 65, 91	V <sub>DD</sub>	Power Supply	Power supply inputs to the core of the device. Should be connected to 3.3V power supply.
17, 40, 67, 90	V <sub>SS</sub>	Ground	Ground for the I/O circuitry if the device. Should be connected to ground of the system.
5, 10, 14, 21, 26, 55, 60, 71, 76	V <sub>SSQ</sub>	Ground	Ground for the device. Should be connected to ground of the system.
4, 11, 20, 27, 54, 61, 70, 77	V <sub>DDQ</sub>	I/O Power Supply	Power supply for the I/O circuitry. Should be connected to a 3.3V power supply.
1, 16, 30, 50–51, 66, 80	NC	-	No connects.
38, 39, 42, 43	DNU	-	Do not use pins. Should be left unconnected or tied LOW.

## Notes:

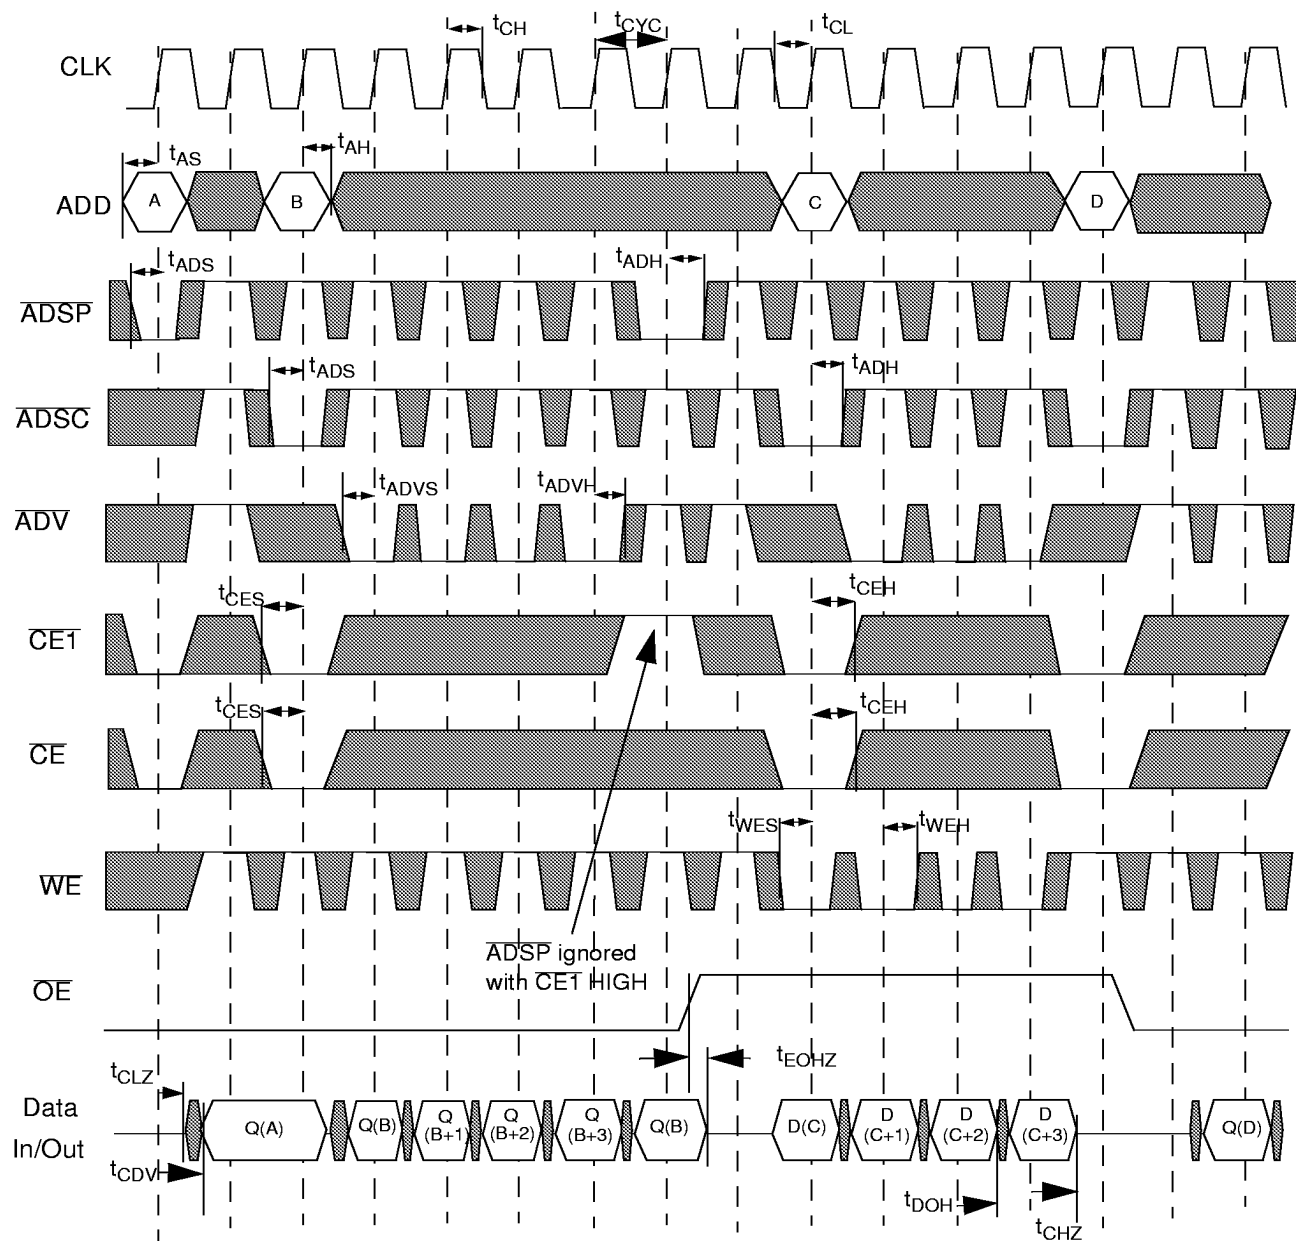

9. Unless otherwise noted, test conditions assume signal transition time of 3.0ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I<sub>OL</sub>/I<sub>OH</sub> and load capacitance. Shown in (a) and (b) of AC test loads.
10. t<sub>CHZ</sub>, t<sub>CLZ</sub>, t<sub>EOHZ</sub>, and t<sub>EOLZ</sub> are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.
11. At any given voltage and temperature, t<sub>CHZ</sub> (max) is less than t<sub>CLZ</sub> (min).
12. This parameter is sampled and not 100% tested.

## Timing Diagrams

## READ/WRITE Timing

Device originally  
deselected

WE is the combination of BWE,  $BWS_{[3:0]}$  and  $\overline{GW}$  to define a write cycle (see write cycle definition table).

$\overline{CE}$  is the combination of  $CE_2$  and  $\overline{CE}_3$ . All chip selects need to be active in order to select the device. RAX stands for Read Address X, WA stands for Write Address X, Dx stands for Data-in X, Qx stands for Data-out X

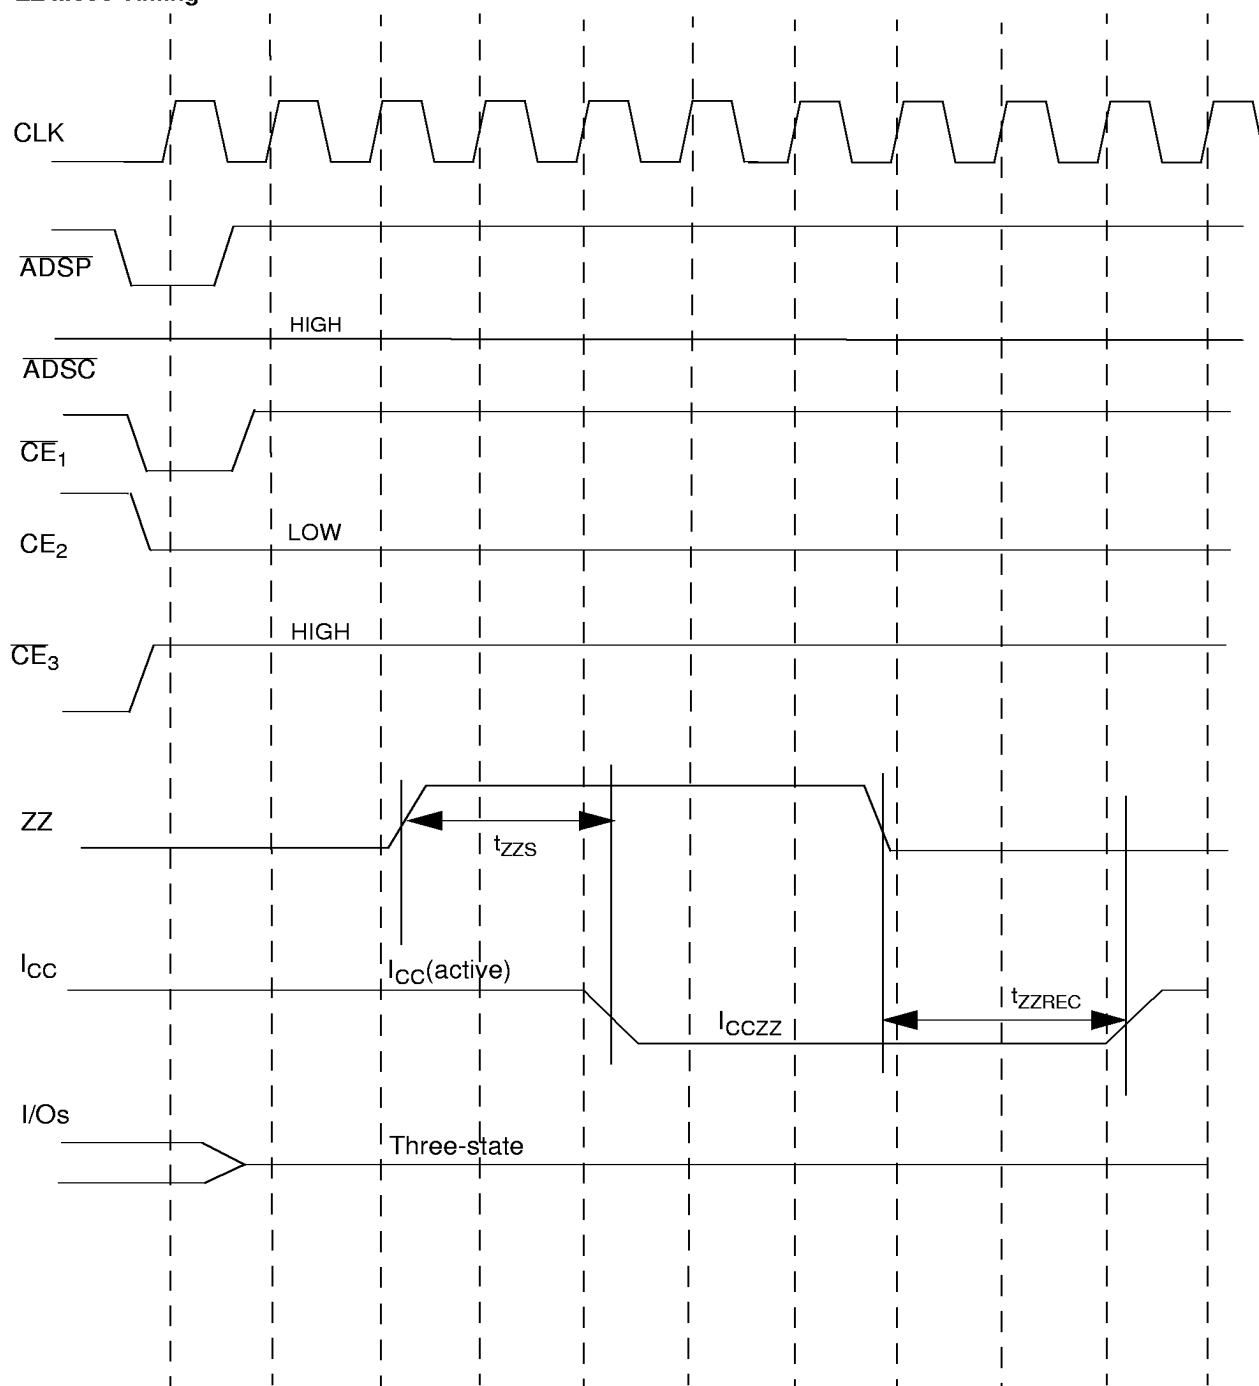

■ = DON'T CARE ■ = UNDEFINED
