

## 3.3V/5V or Adjustable-Output, Single-Cell DC-DC Converters

MAX866/MAX867

### General Description

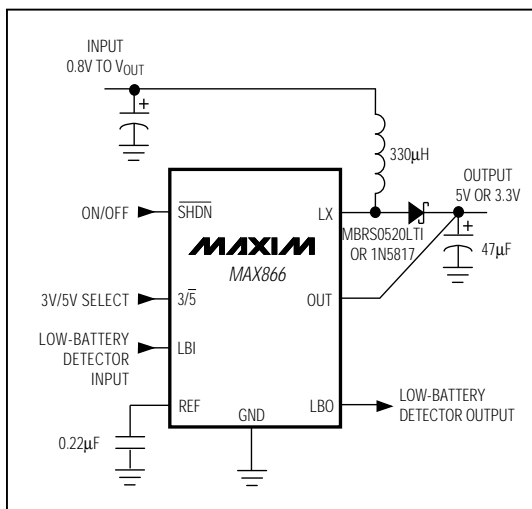

The MAX866 and MAX867 are ultra-small, high-efficiency, CMOS, step-up, DC-DC switching regulators for 1-cell battery-powered systems. The MAX866 accepts a positive input voltage between 0.8V and  $V_{OUT}$  and converts it to a higher, pin-selectable output voltage of 3.3V or 5V. The MAX867 adjustable version accepts 0.8V to 6.0V input voltages and generates a higher adjustable output voltage in the 2.7V to 6.0V range. Typical efficiencies are greater than 80%. Typical no-load supply current is 100 $\mu$ A (1 $\mu$ A in shutdown).

The MAX866/MAX867 combine ultra-low quiescent supply current and high efficiency to give maximum battery life. Its high switching frequency permits the use of small, low-cost inductors and capacitors. Additionally, internal peak-current limiting protects the IC.

### Applications

Pagers  
Remote Controls  
Detectors  
1-Cell Battery-Operated Equipment  
Backup Supplies

### Typical Operating Circuit

### Features

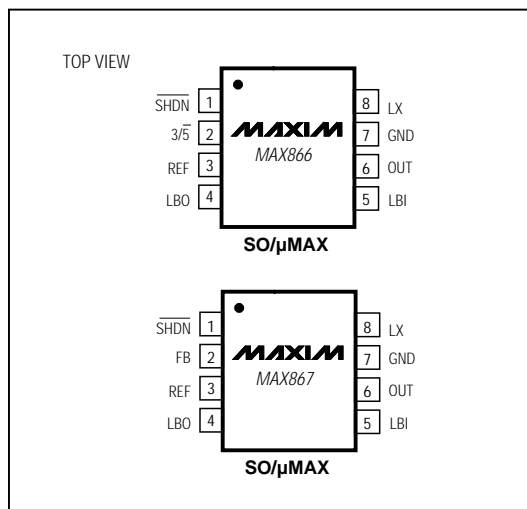

- ♦ 0.8V to 6.0V Input Supply Voltage
- ♦ 0.9V Guaranteed Start-Up Supply Voltage
- ♦ >80% Efficiency Over Wide Load Range
- ♦ 100 $\mu$ A No-Load Battery Current ( $V_{OUT} = 3.3V$ )
- ♦ 1 $\mu$ A Shutdown Mode
- ♦ Up to 250kHz Switching Frequency
- ♦  $\pm 1.5\%$  Reference Tolerance
- ♦ Low-Battery Detector (LBI/LBO)
- ♦ Available in Ultra-Small 8-Pin  $\mu$ MAX Package (1.11mm high)
- ♦ Circuit Fits in 0.2in<sup>2</sup>

### Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE
MAX866C/D	0°C to +70°C	Dice*
MAX866ESA	-40°C to +85°C	8 SO
MAX866EUA	-40°C to +85°C	8 $\mu$ MAX
MAX867C/D	0°C to +70°C	Dice*
MAX867ESA	-40°C to +85°C	8 SO
MAX867EUA	-40°C to +85°C	8 $\mu$ MAX

\* Dice are tested at  $T_A = +25^\circ\text{C}$  only.

### Pin Configurations

## 3.3V/5V or Adjustable-Output, Single-Cell DC-DC Converters

### ABSOLUTE MAXIMUM RATINGS

Supply Voltage (OUT to GND) .....-0.3V, +7V  
 Switch Voltage (LX to GND) .....-0.3V, +7V  
 SHDN, LBO to GND .....-0.3V, +7V  
 LBI, REF, 3/5, FB to GND .....-0.3V, (V<sub>OUT</sub> + 0.3V)  
 Reference Current (I<sub>REF</sub>) .....2.5mA  
 Continuous Power Dissipation (T<sub>A</sub> = +70°C)  
   SO (derate 5.88mW/°C above +70°C) .....471mW  
   μMAX (derate 4.1mW/°C above +70°C) .....330mW

Reverse Battery Current (T<sub>A</sub> ≤ +45°C) (Note 1) .....750mA  
 Operating Temperature Ranges  
   MAX86\_C/D .....0°C to +70°C  
   MAX86\_E\_A .....-40°C to +85°C  
 Junction Temperature .....+150°C  
 Storage Temperature Range .....-65°C to +160°C  
 Lead Temperature (soldering, 10sec) .....+300°C

**Note 1:** Reverse battery current is measured from the *Typical Operating Circuit's* battery input terminal to GND when the battery is connected backwards. A reverse current of 750mA will not exceed the package dissipation limits but, if left for an extended time (more than ten minutes), may degrade performance.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ELECTRICAL CHARACTERISTICS

### ELECTRICAL CHARACTERISTICS (continued)

(Circuit of Figure 2,  $V_{IN} = 1.2V$ ,  $I_{LOAD} = 0mA$ ,  $T_A = +25^{\circ}C$ , unless otherwise noted.)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
LBI Input Hysteresis			25		mV
LBO Output Voltage Low	$I_{SINK} = 2mA$ , open-drain output			0.4	V
LBO Output Leakage Current	$LBO = 5V$			1	$\mu A$
SHDN, $3/5$ Input Voltage Low				$0.08 \times V_{OUT}$	V
SHDN, $3/5$ Input Voltage High		$0.32 \times V_{OUT}$			V
SHDN, $3/5$ , FB, LBI Input Current	$LBI = 1.5V$ , $FB = 1.5V$ , $SHDN = 0V$ or $3V$ , $3/5 = 0V$ or $3V$		$\pm 40$	$\pm 100$	nA
FB Voltage	MAX867, output in regulation	1.22	1.25	1.28	V
Output Voltage Range	MAX867	2.7		6.0	V

**Note 2:** Output current specified with circuit of Figure 2 and CoilCraft D01608-334 inductor for test purposes only. More (or less) output current can be supplied with other coil types depending on inductance value and coil resistance. See *Typical Operating Characteristics* for other coil types. Output voltage and output current are guaranteed over this  $V_{IN}$  operating range once the device has started up. Actual  $V_{IN}$  start-up voltage depends on load current.

**Note 3:** Output voltage specifications over temperature are guaranteed by design to limits that are 6 sigma from either side of the mean.

**Note 4:** Current measured into OUT.  $V_{OUT}$  is forced to 3.47V to maintain LX off when measuring device current.

## Pin Description

PIN		NAME	FUNCTION
MAX866	MAX867		
1	1	SHDN	Shutdown Input. When low, the entire circuit is off and $V_{OUT} = V_{IN} - V_D$ , where $V_D$ is the forward voltage drop of the external Schottky rectifier.
2	—	3/5	Selects the output voltage; connect to GND for 5V output, and to OUT for 3.3V output.
—	2	FB	Feedback Input for adjustable-output operation. Connect to an external resistor voltage divider between OUT and GND.
3	3	REF	1.25V Reference Voltage Output. Bypass with $0.22\mu\text{F}$ to GND ( $0.1\mu\text{F}$ if there is no external reference load). Maximum load capability is $250\mu\text{A}$ source, $20\mu\text{A}$ sink.
4	4	LBO	Low-Battery Output. An open-drain N-channel MOSFET sinks current when the voltage at LBI drops below 1.25V.
5	5	LBI	Low-Battery Input. When the voltage on LBI drops below 1.25V, LBO sinks current. If not used, connect to $V_{IN}$ .
6	6	OUT	Connect OUT to the regulator output. OUT provides bootstrap power to the IC.
7	7	GND	Power Ground. Must be low impedance; solder directly to ground plane.
8	8	LX	N-Channel Power-MOSFET Drain

## 3.3V/5V or Adjustable-Output, Single-Cell DC-DC Converters

MAX866/MAX867

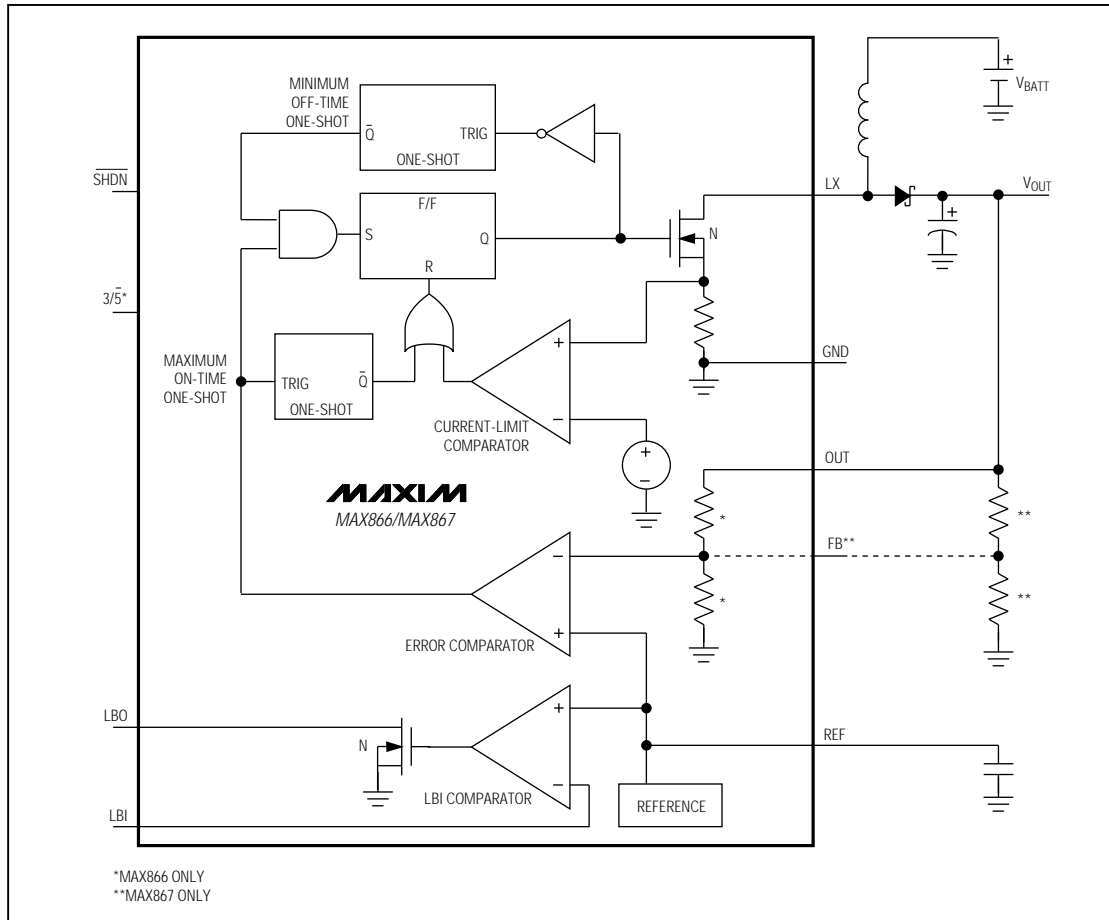

Figure 1. Block Diagram

### Detailed Description

#### Operating Principle

The MAX866/MAX867 combine a switch-mode regulator, N-channel power MOSFET, precision voltage reference, and power-fail detector in a single monolithic device. The MOSFET is a "sense-FET" type for best efficiency, and has a very low gate threshold voltage to ensure start-up with low battery voltages (0.8V typ).

#### PFM Control Scheme

The MAX866/MAX867 control scheme (Figure 1) combines low-voltage efficiency (80% typ) with low battery

drain (100 $\mu$ A typ). There is no oscillator; switching is accomplished by a pair of one shots that set a maximum LX on-time (4.5 $\mu$ s typ) and a minimum LX off-time (1 $\mu$ s). LX on-time will be terminated early if the inductor current reaches 0.5A before 4.5 $\mu$ s elapses. With the standard application circuit (Figure 2a), LX current is typically less than 50mA, so LX on-time is normally not terminated by the 0.5A limit and lasts the complete 4.5 $\mu$ s. The LX on-resistance is typically 1 $\Omega$  to minimize switch losses. The MAX866/MAX867 switching frequency depends on load, input voltage, and inductor value, and it can range up to 250kHz with typical component values.

## 3.3V/5V or Adjustable-Output, Single-Cell DC-DC Converters

### Voltage Reference

The precision voltage reference is suitable for driving external loads, such as an analog-to-digital converter. The voltage-reference output changes less than  $\pm 2\%$  when sourcing up to  $250\mu\text{A}$  and sinking up to  $20\mu\text{A}$ . If the reference drives an external load, bypass it with  $0.22\mu\text{F}$  to GND. If the reference is unloaded, bypass it with at least  $0.1\mu\text{F}$ .

### Logic Inputs and Outputs

The  $3/\overline{5}$  input is internally diode clamped to GND and OUT, and should not be connected to signals outside this range. The  $\overline{\text{SHDN}}$  input and LBO output (open-drain) are not clamped to  $V+$  and can be pulled as high as  $7\text{V}$  regardless of the voltage at OUT. **Do not leave control inputs ( $3/\overline{5}$ , LBI, or  $\overline{\text{SHDN}}$ ) floating.**

### Design Procedure

#### Output Voltage Selection

For the MAX866, you can select a  $3.3\text{V}$  or  $5\text{V}$  output voltage under logic control, or by tying  $3/\overline{5}$  to GND or OUT. The MAX867's output voltage is set by two resistors, R1 and R2 (Figure 2b), which form a voltage divider between the output and FB. Use the following equation to determine the output voltage:

$$V_{\text{OUT}} = V_{\text{REF}} \left( \frac{R1 + R2}{R2} \right)$$

where  $V_{\text{REF}} = 1.25\text{V}$ .

To simplify resistor selection:

$$R1 = R2 \left( \frac{V_{\text{OUT}}}{V_{\text{REF}}} - 1 \right)$$

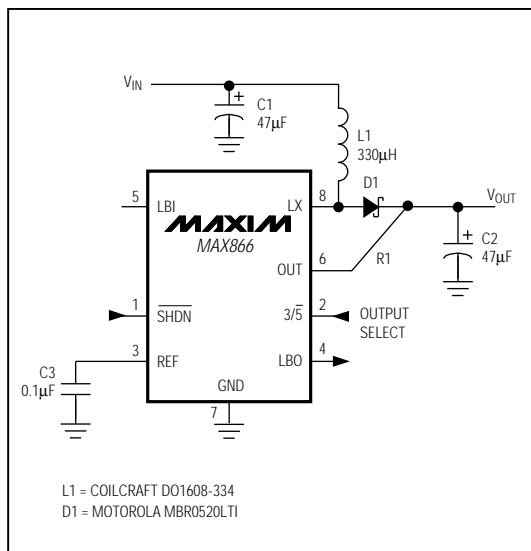

Figure 2a. Standard Application Circuit—Preset Output Voltage

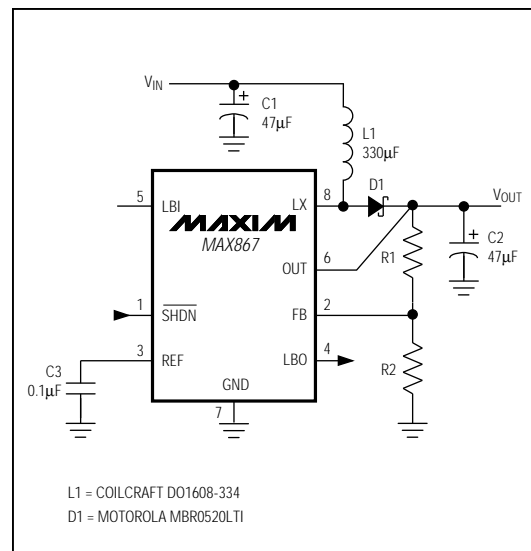

Figure 2b. Standard Application Circuit—Adjustable Output Voltage

## 3.3V/5V or Adjustable-Output, Single-Cell DC-DC Converters

Figure 3. Low-Battery Detector Circuits

Since the input bias current at FB has a maximum value of 100nA, large values (10k $\Omega$  to 300k $\Omega$ ) can be used for R1 and R2 with no significant accuracy loss. For 1% error, the current through R1 should be at least 100 times FB's bias current.

### Low-Battery Detection, $V_{TH} \geq 1.25V$

The MAX866 series contains an on-chip comparator for low-battery detection. If the voltage at LBI falls below the regulator's internal reference voltage (1.25V), LBO (an open-drain output) sinks current to GND. The low-battery monitor's threshold is set by two resistors, R3 and R4 (Figure 3). Set the threshold voltage using the following equation:

$$R3 = R4 \left( \frac{V_{TH}}{V_{REF}} - 1 \right)$$

where  $V_{TH}$  is the desired threshold of the low-battery detector and  $V_{REF}$  is the internal 1.25V reference.

Since the LBI current is less than 100nA, large resistor values (typically 10k $\Omega$  to 300k $\Omega$ ) can be used for R3 and R4 to minimize loading of the input supply.

When the voltage at LBI is below the internal threshold, LBO sinks current to GND. Connect a pull-up resistor of 100k $\Omega$  or more from LBO to OUT when driving CMOS circuits. When LBI is above the threshold, the LBO output is off. If the low-battery comparator is not used, connect LBI to  $V_{IN}$  and leave LBO open.

### Low-Battery Detection, $V_{TH} < 1.25V$

When the low-battery detection threshold voltage is below 1.25V, use the circuit shown on the right in

Figure 4. Low-Voltage Start-Up Circuit

Figure 3. This circuit uses  $V_{OUT}$  (3.3V or 5.0V in the MAX866, adjustable in MAX867) as a reference. The voltage divider formed by R5 and R6 allows the effective trip point of  $V_{IN}$  to be set below 1.25V. R6 is usually set to approximately 100k $\Omega$ , and R5 is given by the formula:

$$R5 = [R6 \times (V_{REF} - V_{TH})] / (V_{OUT} - V_{REF})$$

Note that LBI drops below the 1.25V LBI threshold trip point when either  $V_{IN}$  or  $V_{OUT}$  is low.

Since  $V_{OUT}$  regulation and the LBI threshold are derived from the same internal voltage reference, they track together over temperature.

### Low-Battery Start-Up

The MAX866/MAX867 are bootstrapped circuits; they can start under no-load conditions at much lower battery voltages than under full load. Once started, the output can maintain a moderate load as the battery voltage decreases below the start-up voltage (see *Typical Operating Characteristics*). The circuit shown in Figure 4 allows the circuit to start with no load, then uses the LBI circuit and an external low-threshold P-channel MOSFET switch to apply the load after the output has started.

Resistors R7 and R8 are selected to trip the LBI detector at about 90% of the output voltage. On start-up, LBI and LBO are low, Q2 is off, and transistor Q1's gate is held high by R11. This disconnects the load, allowing the MAX866 to bootstrap itself at the lowest possible voltage. When the output reaches its final output voltage, LBI and LBO go high, turning on Q2, Q1, and the load.

### Inductor Selection

An inductor value of 330 $\mu$ H works well in most applications, supplying loads over 10mA and allowing typical start-up voltages of 0.8V. The inductor value is not critical, and the MAX866/MAX867 can operate with values from 22 $\mu$ H to 1mH. In general, smaller inductor values supply more output current while larger values start with lower input voltage. Several inductor suppliers and part numbers are listed in Tables 1 and 2.

The peak inductor current should not exceed the inductor's current rating. Since the MAX866/MAX867 current limit of 0.5A will not be reached in most applications, the peak coil current ( $I_{PK}$ ) is:

$$I_{PK} = (V_{IN(max)} \times 4.5\mu s) / L$$

For a typical 1-cell alkaline design,  $V_{IN(max)}$  is 1.55V, so:

$$I_{PK} = (1.55V \times 4.5\mu s) / 330\mu H = 21.14mA$$

which is well within the ratings of most surface-mount coils. Higher efficiency and output current are achieved with lower inductor resistance, but unfortunately this is inversely related to physical size. Table 2 indicates resistance and height for each coil. Some of the smallest coils have resistances over 10 $\Omega$ , and will not provide the same output power or efficiency of a 1 $\Omega$  coil. At light loads however (below 5mA), the efficiency differences between low- and high-resistance coils may be only a percent or two. The *Typical Operating Characteristics* graphs show efficiency and output current plots for 1.5 $\Omega$  and 2.9 $\Omega$ , 330 $\mu$ H coils.

### Capacitor Selection

A 47 $\mu$ F, 6V, 0.85 $\Omega$ , surface-mount tantalum (SMT) output filter capacitor typically provides 15mV output ripple when stepping up from 0.9V to 1.4V at 10mA. Smaller capacitors (down to 10 $\mu$ F with higher ESRs) are acceptable for light loads or in applications that can

\* Shielded

\*\* Low cost

tolerate higher output ripple. Values in the 10 $\mu$ F to 47 $\mu$ F range are recommended.

The equivalent series resistance (ESR) of both bypass and filter capacitors affects efficiency and output ripple. Use low-ESR capacitors for best performance, or connect two or more filter capacitors in parallel. Low-ESR, SMT tantalum capacitors are currently available from Sprague (595D series) and AVX (TPS series). See Table 1 for a list of suggested capacitor suppliers.

### Rectifier Diode

For optimum performance, a switching Schottky diode (such as the 1N5817 or MBR0520LT1) is recommended. Refer to Table 1 for a list of component suppliers. For low output power applications, a PN-junction switching diode (such as the 1N4148) will also work well, although its greater forward voltage drop will reduce efficiency and raise the start-up voltage.

### PC Layout and Grounding

The circuit's high-frequency operation makes PC layout important for minimizing ground bounce and noise. Keep the IC's GND pin and the ground leads of C1 and C2 (Figure 2) less than 0.2in (5mm) apart. Also keep all connections to the FB and LX pins as short as possible. To maximize output power and efficiency and minimize output ripple voltage, use a ground plane and solder the IC's GND (pin 7) directly to the ground plane.
