

# Variable Reluctance Sensor Interfaces with Differential Input and Adaptive Peak Threshold

## General Description

The MAX9924–MAX9927 variable reluctance (VR or magnetic coil) sensor interface devices are ideal for position and speed sensing for automotive crankshafts, camshafts, transmission shafts, etc. These devices integrate a precision amplifier and comparator with selectable adaptive peak threshold and zero-crossing circuit blocks that generate robust output pulses even in the presence of substantial system noise or extremely weak VR signals.

The MAX9926/MAX9927 are dual versions of the MAX9924/MAX9925, respectively. The MAX9924/MAX9926 combine matched resistors with a CMOS input precision operational amplifier to give high CMRR over a wide range of input frequencies and temperatures. The MAX9924/MAX9926 differential amplifiers provide a fixed gain of 1V/V. The MAX9925/MAX9927 make all three terminals of the internal operational amplifier available, allowing greater flexibility for gain. The MAX9926 also provides a direction output that is useful for quadrature-connected VR sensors that are used in certain high-performance engines. These devices interface with both new-generation differential VR sensors as well as legacy single-ended VR sensors.

The MAX9924/MAX9925 are available in the 10-pin  $\mu$ MAX® package, while the MAX9926/MAX9927 are available in the 16-pin QSOP package. All devices are specified over the -40°C to +125°C automotive temperature range.

## Applications

Camshaft VRS Interfaces  
Crankshaft VRS Interfaces  
Vehicle Speed VRS Interfaces

## Features

- ◆ Differential Input Stage Provides Enhanced Noise Immunity
- ◆ Precision Amplifier and Comparator Allows Small-Signal Detection
- ◆ User-Enabled Internal Adaptive Peak Threshold or Flexible External Threshold
- ◆ Zero-Crossing Detection Provides Accurate Phase Information

## Ordering Information

| PART                 | TEMP RANGE      | PIN-PACKAGE  |
|----------------------|-----------------|--------------|
| <b>MAX9924</b> UAUB+ | -40°C to +125°C | 10 $\mu$ MAX |
| MAX9924 UAUB/V+      | -40°C to +125°C | 10 $\mu$ MAX |
| <b>MAX9925</b> AUB+  | -40°C to +125°C | 10 $\mu$ MAX |
| <b>MAX9926</b> UAEE+ | -40°C to +125°C | 16 QSOP      |
| MAX9926 UAEE/V+      | -40°C to +125°C | 16 QSOP      |
| <b>MAX9927</b> AEE+  | -40°C to +125°C | 16 QSOP      |
| MAX9927 AEE/V+       | -40°C to +125°C | 16 QSOP      |

+ Denotes a lead(Pb)-free/RoHS-compliant package.

/V denotes an automotive qualified part.

## Simplified Block Diagram

# Variable Reluctance Sensor Interfaces with Differential Input and Adaptive Peak Threshold

## ABSOLUTE MAXIMUM RATINGS

V<sub>CC</sub> to GND .....-0.3V to + 6V  
 All Other Pins.....-0.3V to (V<sub>CC</sub> + 0.3V)  
 Current into IN+, IN-, IN<sub>+</sub>, IN<sub>-</sub> .....±40mA  
 Current into All Other Pins .....±20mA  
 Output Short-Circuit (OUT<sub>-</sub>, OUT) to GND.....10s  
 Continuous Power Dissipation (T<sub>A</sub> = +70°C) (Note 1)  
     10-Pin  $\mu$ MAX (derate 8.8mW/°C above +70°C) .....707.3mW  
     16-Pin QSOP (derate 9.6mW/°C above +70°C) .....771.5mW

Operating Temperature Range .....-40°C to +125°C  
 Junction Temperature .....+150°C  
 Storage Temperature Range .....-65°C to +150°C  
 Lead Temperature (soldering, 10s) .....+300°C  
 Soldering Temperature (reflow) .....+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## PACKAGE THERMAL CHARACTERISTICS (Note 1)

|                                                                         |                                                                         |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------|
| $\mu$ MAX                                                               | QSOP                                                                    |
| Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ) .....113.1°C/W | Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ) .....103.7°C/W |
| Junction-to-Case Thermal Resistance ( $\theta_{JC}$ ) .....42°C/W       | Junction-to-Case Thermal Resistance ( $\theta_{JC}$ ) .....37°C/W       |

**Note 1:** Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maxim-ic.com/thermal-tutorial](http://www.maxim-ic.com/thermal-tutorial).

## ELECTRICAL CHARACTERISTICS

(V<sub>CC</sub> = 5V, V<sub>GND</sub> = 0V, MAX9925/MAX9927 gain setting = 1V/V, Mode A1, V<sub>BIAS</sub> = 2.5V, V<sub>PULLUP</sub> = 5V, R<sub>PULLUP</sub> = 1k $\Omega$ , C<sub>COU</sub>T = 50pF. T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless otherwise noted. Typical values are at T<sub>A</sub> = +25°C.) (Note 2)

## Detailed Description

The MAX9924–MAX9927 interface with variable reluctance (VR) or magnetic coil sensors. These devices produce accurate pulses aligned with flywheel gear-teeth even when the pickup signal is small and in the presence of large amounts of system noise. They interface with new-generation differential VR sensors as well as legacy single-ended VR sensors.

The MAX9924/MAX9925 integrate a precision op amp, a precision comparator, an adaptive peak threshold block, a zero-crossing detection circuit, and precision matched resistors (MAX9924). The MAX9926 and MAX9927 are dual versions of the MAX9924 and MAX9925, respectively. The MAX9926 also provides a rotational output that is useful for quadrature-connected VR sensors used in certain high-performance engines.

The input op amp in the MAX9925/MAX9927 are typically configured as a differential amplifier by using four external resistors (the MAX9924/MAX9926 integrate precision-matched resistors to give superior CMRR performance). This input differential amplifier rejects input common-mode noise and converts the input differential signal from a VR sensor into a single-ended signal. The internal comparator produces output pulses by compar-

ing the output of the input differential amplifier with a threshold voltage that is set depending on the mode that the device is in (see the *Mode Selection* section).

## Mode Selection

The MAX9924/MAX9926 provide four modes of operation: Mode A1, Mode A2, Mode B, and Mode C as determined by voltages applied to inputs ZERO\_EN and INT\_THRS (see Tables 1, 2, and 3). In Modes A1 and A2, the internal adaptive peak threshold and the zero-crossing features are enabled. In Mode A2, an internally generated reference voltage is used to bias the differential amplifier and all internal circuitry instead of an external voltage connected to the BIAS input—this helps reduce external components and design variables leading to a more robust application. In Mode B, the adaptive peak threshold functionality is disabled, but zero-crossing functionality is enabled. In this mode, an external threshold voltage is applied at EXT allowing application-specific adaptive algorithms to be implemented in firmware. In Mode C, both the adaptive peak threshold and zero-crossing features are disabled and the device acts as a high-performance differential amplifier connected to a precision comparator (add external hysteresis to the comparator for glitch-free operation).

**Table 1. MAX9924/MAX9926 Operating Modes**

| OPERATING MODE | SETTING         |                 | DEVICE FUNCTIONALITY |                         |                     |
|----------------|-----------------|-----------------|----------------------|-------------------------|---------------------|
|                | ZERO_EN         | INT_THRS        | ZERO CROSSING        | ADAPTIVE PEAK THRESHOLD | BIAS VOLTAGE SOURCE |
| A1             | V <sub>CC</sub> | V <sub>CC</sub> | Enabled              | Enabled                 | External            |
| A2             | GND             | GND             | Enabled              | Enabled                 | Internal Ref        |

# Variable Reluctance Sensor Interfaces with Differential Input and Adaptive Peak Threshold

## Differential Amplifier

The input operational amplifier is a rail-to-rail input and output precision amplifier with CMOS input bias currents, low offset voltage ( $V_{OS}$ ) and drift. A novel input architecture eliminates crossover distortion at the operational amplifier inputs normally found in rail-to-rail input structures. These features enable reliable small-signal detection for VR sensors.

The MAX9924/MAX9926 include on-chip precision-matched low-ppm resistors configured as a differential amplifier. High-quality matching and layout of these resistors produce extremely high DC and AC CMRR that is important to maintain noise immunity. The matched ppm-drift of the resistors guarantees performance across the entire  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  automotive temperature range.

## Bias Reference

In Modes A1, B, and C, a well-decoupled external resistor-divider generates a  $V_{CC}/2$  signal for the BIAS input that is used to reference all internal electronics in the device. BIAS should be bypassed with a  $0.1\mu\text{F}$  and  $10\mu\text{F}$  capacitor in parallel with the lower half of the resistor-divider forming a lowpass filter to provide a stable external BIAS reference.

The minimum threshold, adaptive peak threshold, zero-crossing threshold signals are all referenced to this voltage. An input buffer eliminates loading of resistor-dividers due to differential amplifier operation. Connect BIAS to ground when operating in Mode A2. An internal ( $2.5\text{V}$  typical) reference is used in Mode A2, eliminating external components.

## Adaptive Peak Threshold

Modes A1 and A2 in the MAX9924-MAX9927 use an internal adaptive peak threshold voltage to trigger the output comparator. This adaptive peak threshold voltage scheme provides robust noise immunity to the input VR signal, preventing false triggers from occurring due to broken tooth or off-centered gear-tooth wheel. See Figure 1.

The sensor signal at the output of the differential gain stage is used to generate a cycle-by-cycle adaptive peak threshold voltage. This threshold voltage is  $1/3$  of the peak of the previous cycle of the input VR signal. As the sensor signal peak voltage rises, the adaptive peak threshold voltage also increases by the same ratio. Conversely, decreasing peak voltage levels of the input VR signal causes the adaptive peak threshold voltage used to trigger the next cycle also to decrease to a new lower level. This threshold voltage then provides an arming level for the zero-crossing circuit of the comparator (see the *Zero Crossing* section).

If the input signal voltage remains lower than the adaptive peak threshold for more than  $85\text{ms}$ , an internal watchdog timer drops the threshold level to a default minimum threshold ( $V_{\text{MIN\_THRESH}}$ ). This ensures pulse recognition recovers even in the presence of intermittent sensor connection.

The internal adaptive peak threshold can be disabled and directly fed from the EXT input. This mode of operation is called Mode B, and allows implementations of custom threshold algorithms in firmware. This EXT voltage is typically generated by filtering a PWM-modulated output from an onboard microcontroller ( $\mu\text{C}$ ). An external operational amplifier can also be used to construct an active lowpass filter to filter the PWM-modulated EXT signal.

Figure 1. Adaptive Peak Threshold Operation

# Variable Reluctance Sensor Interfaces with Differential Input and Adaptive Peak Threshold

## Zero Crossing

The zero-crossing signal provides true timing information for engine-control applications. The zero-voltage level in the VR sensor signal corresponds to the center of the gear-tooth and is the most reliable marker for position/angle-sensing applications. Since the output of the differential amplifier is level-shifted to the BIAS voltage, the zero of the input VR signal is simply BIAS. The comparator output state controls the status of the input switch that changes the voltage at its noninverting input from the adaptive/external threshold level to the BIAS level. The difference in these two voltages then effectively acts as hysteresis for the comparator, thus providing noise immunity.

## Comparator

The internal comparator is a fast open-drain output comparator with low input offset voltage and drift. The comparator precision affects the ability of the signal chain to resolve small VR sensor signals. An open-drain output allows the comparator to easily interface to a variety of  $\mu\text{C}$  I/O voltages.

When operating the MAX9924/MAX9925/MAX9926 in Mode C, external hysteresis can be provided by adding external resistors (see Figures 5 and 8). The high and low hysteresis thresholds in Mode C can be calculated using the following equations,

$$V_{TH} = \left( \frac{R1(V_{PULLUP} - V_{BIAS})}{R1 + R2 + R_{PULLUP}} \right) + V_{BIAS}$$

and

$$V_{TL} = \left( \frac{R2}{R1 + R2} \right) \times V_{BIAS}$$

## Rotational Direction Output (MAX9926 Only)

For quadrature-connected VR sensors, the open-drain output DIRN indicates the rotational direction of inputs IN1 and IN2 based on the output state of COUT1 and COUT2. DIRN goes high when COUT1 is leading COUT2, and low when COUT1 is following COUT2.

## Applications Information

### Bypassing and Layout Considerations

Good power-supply decoupling with high-quality bypass capacitors is always important for precision analog circuits. The use of an internal charge pump for the front-end amplifier makes this more important. Bypass capacitors create a low-impedance path to ground for noise present on the power supply.

The minimum impedance of a capacitor is limited to the effective series resistance (ESR) at the self-resonance frequency, where the effective series inductance (ESL) cancels out the capacitance. The ESL of the capacitor dominates past the self-resonance frequency resulting in a rise in impedance at high frequencies.

Bypass the power supply of the MAX9924-MAX9927 with multiple capacitor values in parallel to ground. The use of multiple values ensures that there will be multiple self-resonance frequencies in the bypass network, lowering the combined impedance over frequency. It is recommended to use low-ESR and low-ESL ceramic surface-mount capacitors in a parallel combination of 10nF, 0.1 $\mu\text{F}$  and 1 $\mu\text{F}$ , with the 10nF placed closest between the VCC and GND pins. The connection between these capacitor terminals and the power-supply pins of the part (both VCC and GND) should be through wide traces (preferably planes), and without vias in the high-frequency current path.
