#### **Features**

- Fast Read Access Time 45 ns
- Low Power CMOS Operation 100 μA max. Standby 20 mA max. Active at 5 MHz
- JEDEC Standard Packages 28-Lead 600-mil PDIP 32-Lead PLCC 28-Lead TSOP and SOIC
- 5V ± 10% Supply
- High Reliability CMOS Technology 2,000V ESD Protection 200 mA Latchup Immunity
- Rapid<sup>™</sup> Programming Algorithm 100 µs/byte (typical)
- CMOS and TTL Compatible Inputs and Outputs
- Integrated Product Identification Code
- Commercial and Industrial Temperature Ranges

#### **Description**

The AT27C256R is a low-power, high performance 262,144 bit one-time programmable read only memory (OTP EPROM) organized 32K by 8 bits. It requires only one 5V power supply in normal read mode operation. Any byte can be accessed in less than 45 ns, eliminating the need for speed reducing WAIT states on high performance microprocessor systems.

Atmel's scaled CMOS technology provides low active power consumption, and fast programming. Power consumption is typically only 8 mA in Active Mode and less than  $10\,\mu\text{A}$  in Standby.

#### **Description** (Continued)

The AT27C256R is available in a choice of industry standard JEDEC-approved one time programmable (OTP) plastic DIP, PLCC, SOIC, and TSOP packages. All devices feature two-line control (CE, OE) to give designers the flexibility to prevent bus contention.

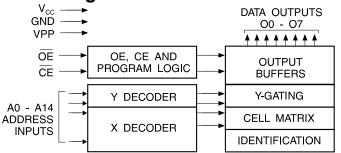

With 32K byte storage capability, the AT27C256R allows firmware to be stored reliably and to be accessed by the system without the delays of mass storage media.

Atmel's 27C256R has additional features to ensure high quality and efficient production use. The Rapid  $^{\!\!\top\!\!}$  Programming Algorithm reduces the time required to program the part and guarantees reliable programming. Programming time is typically only 100  $\mu s/byte$ . The Integrated Product Identification Code electronically identifies the device and manufacturer. This feature is used by industry standard programming equipment to select the proper programming algorithms and voltages.

#### **System Considerations**

Switching between active and standby conditions via the Chip Enable pin may produce transient voltage excursions. Unless accommodated by the system design, these transients may exceed data sheet limits, resulting in device non-conformance. At a minimum, a 0.1  $\mu$ F high frequency, low inherent inductance, ceramic capacitor should be utilized for each device. This capacitor should be connected between the Vcc and Ground terminals of the device, as close to the device as possible. Additionally, to stabilize the supply voltage level on printed circuit boards with large EPROM arrays, a 4.7  $\mu$ F bulk electrolytic capacitor should be utilized, again connected between the Vcc and Ground terminals. This capacitor should be positioned as close as possible to the point where the power supply is connected to the array.

\*NOTICE: Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note: 1. Minimum voltage is -0.6V dc which may undershoot to -2.0V for pulses of less than 20 ns. Maximum output pin voltage is V<sub>CC</sub> + 0.75V dc which may overshoot to +7.0V for pulses of less than 20 ns.

<sup>2.</sup>  $V_{PP}$  may be connected directly to  $V_{CC}$ , except during programming. The supply current would then be the sum of  $I_{CC}$  and  $I_{PP}$ .

## **AC Waveforms for Read Operation** (1)

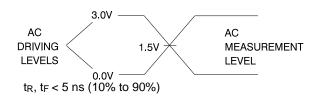

- Notes: 1. Timing measurement reference level is 1.5V for -45 and -55 devices. Input AC drive levels are  $V_{IL} = 0.0V$  and  $V_{IH} = 3.0V$ . Timing measurement reference levels for all other speed grades are  $V_{OL} = 0.8V$  and  $V_{OH} = 2.0V$ . Input AC drive levels are  $V_{IL} = 0.45V$  and  $V_{IH} = 2.4V$ .
  - OE may be delayed up to t<sub>CE</sub> t<sub>OE</sub> after the falling edge of CE without impact on t<sub>CE</sub>.
- 3.  $\overline{\text{OE}}$  may be delayed up to  $t_{\text{ACC}}$   $t_{\text{OE}}$  after the address is valid without impact on  $t_{\text{ACC}}$ .
- 4. This parameter is only sampled and is not 100% tested.
- Output float is defined as the point when data is no longer driven.

#### **Rapid Programming Algorithm**

A 100  $\mu s$   $\overline{CE}$  pulse width is used to program. The address is set to the first location.  $V_{CC}$  is raised to 6.5V and  $V_{PP}$  is raised to 13.0V. Each address is first programmed with one 100  $\mu s$   $\overline{CE}$  pulse without verification. Then a verification/reprogramming loop is executed for each address. In the event a byte fails to pass verification, up to 10 successive 100  $\mu s$  pulses are applied with a verification after each pulse. If the byte fails to verify after 10 pulses have been applied, the part is considered failed. After the byte verifies properly, the next address is selected until all have been checked.  $V_{PP}$  is then lowered to 5.0V and  $V_{CC}$  to 5.0V. All bytes are read again and compared with the original data to determine if the device passes or fails.
