

350mA High Efficiency Step Down LED Driver

FEATURES

- LED drive current up to 350mA
- 12V and 24V system compatible
- Handles transients up to 40V
- Single Pin Control and Dimming function
- Power Efficiency up to 94%
- Drives LED strings of up to 20 volts
- Open and short LED protection
- Parallel configuration for higher output current
- RoHS-compliant TSOT-23 5-lead package

APPLICATIONS

- 12V and 24V Lighting Systems
- Automotive and Aircraft Lighting
- General lighting
- High Brightness 350mA LEDs

ORDERING INFORMATION

Part Number	Quantity per Reel	Package Marking
CAT4201TD-GT3	3000	TF

* Plated Finish: NiPdAu

PIN CONFIGURATION

DESCRIPTION

The CAT4201 is a high efficiency step-down converter optimized to drive high current LEDs. A patent-pending switching control algorithm allows highly efficient and accurate LED current regulation. A single RSET resistor sets the full scale LED string current up to 350mA from supplies as high as 28V.

The switching architecture of the CAT4201 results in extremely low internal power dissipation allowing the device to be housed in a tiny package without the need for dedicated heat sinking. The device is compatible with switching frequencies of up to 1MHz, making it ideal for applications requiring small footprint and low value external inductors.

Analog dimming and LED shutdown control is provided via a single input pin, CTRL. Additional features include overload current protection and thermal shutdown. The device is available in the low profile 5-lead thin SOT23 package and is ideal for space constrained applications.

For Ordering Information details, see page 14.

TYPICAL APPLICATION CIRCUIT

D: Central Schottky CMDSH05-4

L: Sumida CDRH6D26-220

See Table 1 on page 6 for external component selection.

Notes:

- (1) Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions outside of those listed in the operational sections of this specification is not implied. Exposure to any absolute maximum rating for extended periods may affect device performance and reliability.
- (2) The VBAT pin voltage should be at least 3V greater than the total sum of the LED forward voltages in order to operate at nominal LED current.
- (3) During power-up, the slew rate of the input supply should be greater than 5μs.

EXTERNAL COMPONENT SELECTION

Table 1 provides the recommended external components L and C2 that offer the best performance

relative to the LED current accuracy, LED ripple current, switching frequency and component size.

LED current (mA)	1 LED		2 LEDs	
	L inductor (μH)	C2 Capacitor (μF)	L inductor (μH)	C2 Capacitor (μF)
≥150	10	2.2	22	4.7
	22	4.7		
< 150	33	4.7	47	2.2
	47	10		

Table 1. External Component Selection

Note: Larger C2 capacitor values allow to reduce further the LED ripple current if needed.

PIN DESCRIPTION

Pin	Name	Function
1	CTRL	Analog dimming control and shutdown pin.
2	GND	Ground reference.
3	RSET	RSET pin. A resistor connected between the pin and ground sets the average LED current.
4	SW	Interface to the inductor.
5	VBAT	Supply voltage for the device.

PIN FUNCTION

VBAT is the supply input to the device. Typical current conduction into this pin is less than 1mA and voltage transients of up to 40V can be applied. To ensure accurate LED current regulation, the VBAT voltage should be 3V higher than the total forward voltage of the LED string. A bypass capacitor of 4.7μF or larger is recommended between VBAT and GND.

CTRL is the analog dimming and control input. An internal pull-down current of 20μA allows the LEDs to shutdown if CTRL is left floating. Voltages of up to 40V can be safely handled by the CTRL input pin.

When the CTRL voltage is less than 0.9V (typ), the LEDs will shutdown to zero current. When the CTRL voltage is greater than about 2.6V, full scale brightness is applied to the LED output. At voltages of less than around 2.6V, the LED current is progressively dimmed until shutdown.

For lamp replacement applications, or applications where operation in dropout mode is expected, it is recommended that the CTRL pin voltage be derived from the LED cathode terminal.

GND is the ground reference pin. This pin should be connected directly to the ground plane on the PCB.

SW pin is the drain terminal of the internal low resistance high-voltage power MOSFET. The inductor and the Schottky diode anode should be connected to the SW pin. Voltages of up to 40V can be safely handled on the SW pin. Traces going to the SW pin should be as short as possible with minimum loop area. The device can handle safely “open-LED” or “shorted-LED” fault conditions.

RSET pin is regulated at 1.2V. A resistor connected between the RSET pin and ground sets the LED full-scale brightness current. The external resistance value and the CTRL pin voltage determine the LED current during analog dimming.

SIMPLIFIED BLOCK DIAGRAM

Figure 1. CAT4201 Simplified Block Diagram

BASIC OPERATION

The CAT4201 is a high efficiency step-down regulator designed to drive series connected high-power LEDs. LED strings with total forward voltages of up to 20V can be driven with bias currents of up to 350mA.

During the first switching phase, an integrated high voltage power MOSFET allows the inductor current to charge linearly until the peak maximum level is reached, at which point the MOSFET is switched off and the second phase commences, allowing the inductor current to then flow through the Schottky diode circuit and discharge linearly back to zero current.

The switching architecture ensures the device will always operate at the cross-over point between Continuous Conduction Mode (CCM) and Discontinuous Conduction Mode (DCM). This operating mode results in an average LED current which is equal to half of the peak switching current.

LED pin current

The LED current is set by the external RSET resistor connected to the regulated output of the RSET pin. An overall current gain ratio of approximately 2.5A/mA exists between the average LED current and the RSET current, hence the following equation can be used to calculate the LED current.

$$\text{LED Current (A)} \cong 2.5 \times V_{\text{RSET}} (\text{V}) / R_{\text{SET}} (\text{k}\Omega)$$

Table 2 lists the various LED currents and the associated RSET resistors.

LED current (A)	RSET (kΩ)
0.10	33
0.15	21
0.20	15
0.25	12
0.30	10
0.35	8.25

Table 2. RSET Resistor Selection

APPLICATION INFORMATION

Input Voltage Range

The minimum supply voltage required to maintain adequate regulation is set by the cathode terminal voltage of the LED string (i.e the VBAT voltage minus the LED string voltage). When the LED cathode terminal falls below 3V, a loss of regulation occurs.

For applications which may occasionally need to experience supply “dropout” conditions, it is recommended that the CTRL input be used to sense the LED cathode voltage. The CTRL pin can either be tied directly to the cathode terminal (for Lamp Replacement) or connected via a pass-transistor for PWM lighting applications.

Figure 2 shows the regulation performance obtained in dropout, when the CTRL pin is configured to sense the LED cathode voltage.

Figure 2. “Dropout” configured LED Current
(as shown in Typical Application on page 1)

Inductor Selection

For 350mA LED current drive levels, a 22μH inductor value is recommended to provide suitable switching frequency across a wide range of input supply values. For LED current of 150mA or less, a 33μH or 47μH inductor is more suitable.

The inductor must have a maximum current rating which equals or exceeds twice the programmed LED current. For example, when driving LEDs at 350mA, an inductor with at least 700mA current rating must be used. Minor improvements in efficiency can be achieved by selecting inductors with lower series resistance.

Part Number	L (μH)	I rated (A)	LED current (A)
CDRH6D26-100	10	1.5	0.35
CDRH6D26-220	22	1.0	0.35
CDRH6D28-330	33	0.92	0.35
CDRH6D28-470	47	0.8	0.35
CDRH6D28-560	56	0.73	0.35

Table 3. Sumida inductors

Capacitor selection

A 10μF ceramic capacitor C2 across the LED(s) keeps the LED ripple current within ± 15% of nominal for most applications. If needed, a larger capacitor can be used to further reduce the LED current ripple. Any resistance in series with the LED (0.5Ω or more) contributes to reduce the ripple current. The capacitor voltage rating should be equivalent to the maximum expected supply voltage so as to allow for “Open-LED” fault conditions. The capacitor value is independent of the switching frequency or the overall efficiency.

A 4.7μF ceramic input capacitor C1 is recommended to minimize the input current ripple generated on the supply. Using a larger capacitor value further reduces the ripple noise appearing on the supply rail.

If a constant capacitance is needed across temperature and voltage, X5R or X7R dielectric capacitors are recommended.

Schottky Diode

The peak repetitive current rating of the Schottky diode must be greater than the peak current flowing through the inductor. Also the continuous current rating of the Schottky must be greater than the average LED current. The voltage rating of the diode should be greater than the peak supply voltage transient preventing any breakdown or leakage. Central Semiconductor Schottky diode CMDSH05-4 (40V, 500mA rated) is recommended. Schottky diodes rated at 400mA (or higher) continuous current are fine for most applications.

Note: Schottky diodes with extremely low forward voltages (V_F) are not recommended, as they may cause an increase in the LED current.

Dimming Methods

Two methods for PWM dimming control on the LEDs are described below. The first method is to PWM on the control pin, the other method is to turn on and off a second resistor connected to the RSET pin and connected in parallel with R1.

PWM on CTRL pin

A PWM signal from a microprocessor can be used for dimming the LEDs when tied to the CTRL pin. The duty cycle which is the ratio between the On time and the total cycle time sets the dimming factor. The recommended PWM frequency on the CTRL pin is between 100Hz and 2kHz.

Figure 3. PWM at 1kHz on CTRL Pin

Figure 4. LED Current vs. Duty Cycle

Figure 5. Circuit for PWM on CTRL

PWM on RSET pin

Another dimming method is to place in parallel to R1 another resistor with a FET in series, as shown on Figure 6. R1 sets the minimum LED current corresponding to 0% duty cycle. The combined resistor of R1 and Rmax sets the maximum LED current corresponding to 100% duty cycle.

Figure 6. Circuit for PWM on RSET

Operation from high supply voltage above 14V

It is recommended to have a slew rate of 5 μ s or more for applications with supply voltages of 14V and above. When using a high supply voltage of 24V, a 1 Ω or 2 Ω resistor in series with the supply, as shown on Figure 7, is recommended to limit the slew rate of the supply voltage. A 4.7 μ F minimum ceramic capacitor is placed between the VBAT pin and ground. The combination of the series resistor R3 and input capacitor C1 acts as a low pass filter limiting the excessive in-rush currents and overvoltage transients which would otherwise occur during “hot-plug” conditions, thereby protecting the CAT4201 driver.

Figure 7. 24V Application with 5 LEDs

Parallel configuration for driving LEDs beyond 350mA

Several CAT4201 devices can be connected in parallel for driving LEDs with current in excess of 350mA. The CAT4201 driver circuits are connected to the same LED cathode. Figure 8 shows the application schematic for driving 1A into one LED with three CAT4201 connected in parallel. Each CAT4201 is driving the LED with a current set by its RSET resistor. The resulting LED current is equal to the sum of each driver current.

Figure 8. Three CAT4201 in Parallel for 1A LED

CAT4201

Open LED Behavior

If the LEDs are not connected, the CAT4201 stops switching and draws very little current.

At power-up with no load connected, the capacitor C2 is charged-up by the CAT4201. As soon as the bottom side of the capacitor (C2-) reaches 0 volt, as shown on Figure 9, the CAT4201 stops switching and remains in the idle mode only drawing about 0.4mA current from the supply.

Figure 9. Open LED mode

Board Layout

In order to minimize EMI and switching noise, the Schottky diode, the inductor and the output capacitor C2 should all be located close to the driver IC. The input capacitor C1 should be located close to the VBAT pin and the Schottky diode cathode. The CAT4201 ground pin should be connected directly to the ground plane on the PCB. A recommended PCB layout with component location is shown on Figure 10. The LEDs are connected by two wires tied to both sides of the output capacitor C2. The LEDs can be located away from the driver if needed.

Figure 10. Recommended PCB Layout

In order to further reduce the ripple on the supply rail, an optional Pi style filter (C-L-C) can be used. A 10µH inductor rated to the maximum supply current can be used.
