Notes:

1. When $V_D = 0$ V, SCLK and SDIO are low impedance.
2. When selecting 2-wire mode, the user must ensure that a 2-wire start condition (falling edge of SDIO while SCLK is high) does not occur within 300 ns before the rising edge of \overline{RST} .
3. When selecting 2-wire mode, the user must ensure that SCLK is high during the rising edge of \overline{RST} , and stays high until after the first start condition.
4. The Si4827 delays SDIO by a minimum of 300 ns from the V_{IH} threshold of SCLK to comply with the minimum $t_{HD:DAT}$ specification.
5. The maximum $t_{HD:DAT}$ has only to be met when $f_{SCLK} = 400$ kHz. At frequencies below 400 kHz, $t_{HD:DAT}$ may be violated as long as all other timing parameters are met.

4. Functional Description

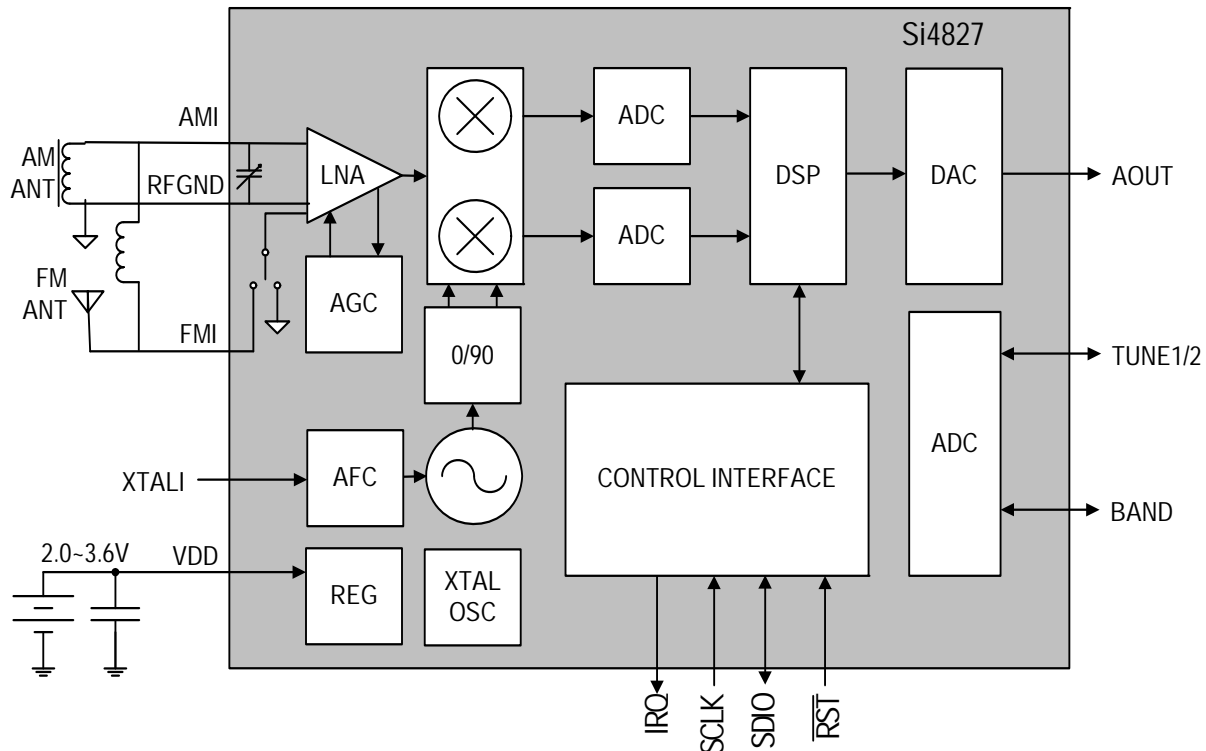

Figure 4. Si4827-A10 Functional Block Diagram

4.1. Overview

The Si4827-A10 is the entry level analog-tuned digital-display digital CMOS AM/FM/SW radio receiver IC that integrates the complete receiver function from antenna input to audio output. Working with an external MCU with LCD/LED driver, Si4827 can output the AM/FM/SW frequencies and band and volume information to display on LCD/LED, while using a simple potentiometer at the front end for analog-tune. Leveraging Silicon Laboratories' proven and patented digital low intermediate frequency (low-IF) receiver architecture, the Si4827 delivers superior RF performance and interference rejection in AM, FM and SW bands. Additionally, the digital core provides advanced audio conditioning for all environments, removing pops, clicks, and loud static in variable signal conditions. The superior control algorithm integrated in Si4827 provides easy and reliable control interface while eliminating all the manual tuned external components used in traditional solutions.

Like other successful audio products from Silicon Labs, Si4827 offers unmatched integration and PCB space savings with minimum external components and a small board area on a single side PCB. The high integration and complete system production test simplifies design-in, increases system quality, and improves manufacturability. The receiver has very low power consumption, runs off two AAA batteries, and delivers the performance benefits of high performance digital radio experience with digital display to the legacy analog-tuned radio market.

The Si4827 provides good flexibility in using the chip. The frequency range of FM/AM/SW bands, de-emphasis value, AM tuning step, and AM soft mute level/rate can be either configured by the MCU or by using external hardware to make a selection. The reference clock of the FM tuner can be provided by either the crystal or by the host MCU within tolerance.

The Si4827 also has flexibility in selecting bands and configuring band properties, enabling masked Host MCU for multiple projects, and reducing the cost of development. Four tuning preferences are available to meet different tuning preference requirements.

4.2. FM Receiver

The Si4827-A10 integrates a low noise amplifier (LNA) supporting the worldwide FM broadcast band (64 to 109 MHz) and the TV audio stations within the frequency range in China area are also supported. The FM band can also be configured to be wider range such as 64–108 MHz in one band.

Pre-emphasis and de-emphasis is a technique used by FM broadcasters to improve the signal-to-noise ratio of FM receivers by reducing the effects of high frequency interference and noise. When the FM signal is transmitted, a pre-emphasis filter is applied to accentuate the high audio frequencies. All FM receivers incorporate a de-emphasis filter which attenuates high frequencies to restore a flat frequency response. Two time constants are used in various regions. The de-emphasis time constant can be chosen to be 50 or 75 μ s. Refer to "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines."

4.3. AM Receiver

The highly integrated Si4827-A10 supports worldwide AM band reception from 504 to 1750 kHz with five sub-bands using a digital low-IF architecture with a minimum number of external components and no manual alignment required. This patented architecture allows for high-precision filtering, offering excellent selectivity and SNR with minimum variation across the AM band. Similar to the FM receiver, the Si4827-A10 optimizes sensitivity and rejection of strong interferers, allowing better reception of weak stations.

To offer maximum flexibility, the receiver supports a wide range of ferrite loop sticks from 180–450 μ H. An air loop antenna is supported by using a transformer to increase the effective inductance from the air loop. Using a 1:5 turn ratio inductor, the inductance is increased by 25 times and easily supports all typical AM air loop antennas, which generally vary between 10 and 20 μ H.

A 9, 10 kHz tuning step can be chosen by the external resistor or host MCU according to the different regions, and AM soft mute level can be programmed by the host MCU to have different tuning experiences. One of the AM bands can be configured as a universal AM band that simultaneously supports 9 kHz and 10 kHz channel spaces for all regional AM standards. Refer to "AN610: Si48xx ATDD Programming Guide" and "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" for more details.

4.4. SW Receiver

The Si4827 supports short wave band receptions from 2.3 to 28.5 MHz in 5 kHz step size increments. It can also be configured to have wide SW band that can be used in SW radio with 1 or 2 SW bands. The Si4827 supports extensive short wave features such as minimal discrete components and no factory adjustments. The Si4827 supports using the FM antenna to capture short wave signals. Refer to "AN610: Si48xx ATDD Programming Guide" and "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" for more details.

4.5. Frequency Tuning

A valid channel can be found by tuning the potentiometer that is connected to the TUNE1 and TUNE2 pin of the Si4827-A10 chip.

To offer easy tuning, the Si4827-A10 also outputs the tuned information to the MCU with LCD/LED driver to display. It will light up the icon on display if the RF signal quality passes a certain threshold when tuned to a valid station. Refer to "AN610: Si48xx ATDD Programming Guide" for more details.

4.6. Band Select

The Si4827-A10 supports worldwide AM band with five sub-bands, US/Europe/Japan/China FM band with five sub-bands, and SW band with 16 sub-bands. Si4827-A10 provides the flexibility to configure the band and band properties at either the MCU side or the tuner side, enabling masked MCU for multiple projects. For details on band selection, refer to "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" and "AN610: Si48xx ATDD Programming Guide".

4.7. Bass and Treble

The Si4827-A10 supports Bass/Treble tone control for superior sound quality. The Si4827-A10 can be set to be default normal, or programmed by the host MCU I²C-compatible 2-wire mode. FM has nine levels Bass/Treble effect and AM/SW has seven levels Bass/Treble effect. For further configuration details, refer to "AN610: Si48xx ATDD Programming Guide".

4.8. Volume Control

The Si4827-A10 not only allows users to use the traditional PVR wheel volume control through an external speaker amplifier, it also supports digital volume control programmed by the host MCU. Si4827-A10 can be programmed to be Bass/Treble mode only or digital volume mode only; it can also be programmed to have the digital volume coexist with Bass/Treble in two modes. Refer to "AN610: Si48xx ATDD Programming Guide" and "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" for more details.

4.9. High Fidelity DAC

High-fidelity digital-to-analog converters (DACs) drive analog audio signals onto the AOUT pin. The audio output may be muted.

4.10. Soft Mute

The soft mute feature is available to attenuate the audio outputs and minimize audible noise in very weak signal conditions. Advanced algorithm is implemented to get a better analog tuning experience. The soft mute feature is triggered by the SNR metric. The SNR threshold for activating soft mute is programmable, as are soft mute attenuation levels and attack and decay rates.

4.11. Reference Clock

The Si4827-A10 supports RCLK input (to XTALI pin) with the spec listed in Table 7. It can be shared with the host MCU to save extra crystal.

An onboard crystal oscillator is available to generate the 32.768 kHz reference when an external crystal and load capacitors are provided. Refer to "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" for more details.

4.12. Reset, Powerup, and Powerdown

Setting the RSTB pin low will disable analog and digital circuitry, reset the registers to their default settings, and disable the bus. Setting the RSTB pin high will bring the device out of reset.

Figure 1 shows typical reset, startup, and shutdown timings for the Si4827. RSTB must be held low (asserted) during any power supply transitions and kept asserted as specified in Figure 1 after the power supplies are ramped up and stable. Failure to assert RSTB as indicated here may cause the device to malfunction and may result in permanent device damage.

A powerdown mode is available to reduce power consumption when the part is idle. Putting the device in powerdown mode will disable analog and digital circuitry while keeping the bus active.

4.13. Memorizing Status

The Si4827-A10 provides the feature to memorize status from the last power down with a simple design on PCB, including frequency of the FM/AM/SW station. Refer to "AN602: Si4822/26/27/40/44 Antenna, Schematic, Layout, and Design Guidelines" for details.

4.14. Programming with Commands

To ease development time and offer maximum customization, the Si4827 provides a simple yet powerful software interface to program the receiver. The device is programmed using commands, arguments, properties, and responses.

To perform an action, the user writes a command byte and associated arguments, causing the chip to execute the given command. Commands control an action such as powerup the device, shut down the device, or get the current tuned frequency. Arguments are specific to a given command and are used to modify the command.

Properties are a special command argument used to modify the default chip operation and are generally configured immediately after powerup. Examples of properties are de-emphasis level and soft mute attenuation threshold.

Responses provide the user information and are echoed after a command and associated arguments are issued. All commands provide a 1-byte status update, indicating interrupt and clear-to-send status information.

For a detailed description of the commands and properties for the Si4827, see "AN610: Si48xx ATDD Programming Guide".
