

LM3405 1.6-MHz, 1-A Constant Current Buck Regulator For Powering LEDs

1 Features

- V_{IN} Operating Range of 3 V to 15 V
- Drives up to 5 High-Brightness LEDs in Series at 1 A
- Thin SOT-6 Package
- 1.6-MHz Switching Frequency
- EN/DIM Input for Enabling and PWM Dimming of LEDs
- 300-m Ω NMOS Switch
- 40-nA Shutdown Current at $V_{IN} = 5$ V
- Internally Compensated Current-mode Control
- Cycle-by-Cycle Current Limit
- Input Voltage UVLO
- Overcurrent Protection
- Thermal Shutdown

2 Applications

- LED Drivers
- Constant Current Sources
- Industrial Lighting
- LED Flashlights

3 Description

The LM3405 is a 1-A constant current buck LED driver designed to provide a simple, high efficiency solution for driving high power LEDs. With a 0.205-V reference voltage feedback control to minimize power dissipation, an external resistor sets the current as required for driving various types of LEDs. Switching frequency is internally set to 1.6 MHz, allowing small surface mount inductors and capacitors to be used. The LM3405 uses current-mode control and internal compensation offering ease of use and predictable, high performance regulation over a wide range of operating conditions. With a maximum input voltage of 15 V, the device can drive up to 3 High-Brightness LEDs in series at 1-A forward current, with the single LED forward voltage of approximately 3.7 V. Additional features include user accessible EN/DIM pin for enabling and PWM dimming of LEDs, thermal shutdown, cycle-by-cycle current limit and overcurrent protection.

Device Information⁽¹⁾

4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision B (April 2013) to Revision C	Page
• Added ESD Ratings table, Feature Description section, Device Functional Modes, Application and Implementation section, Power Supply Recommendations section, Layout section, Device and Documentation Support section, and Mechanical, Packaging, and Orderable Information section	1
• Deleted Soldering information (220°C, maximum) from Absolute Maximum Ratings.....	4
• Changed Thermal resistance, θ_{JA} , in Thermal Information From: 118°C/W To: 182.9°C/W	5

Changes from Revision A (May 2013) to Revision B	Page
• Changed layout of National Semiconductor Data Sheet to TI format	23

5 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NO.	NAME		
1	BOOST	O	Boost voltage that drives the NMOS output switch. A bootstrap capacitor is connected between the BOOST and SW pins.
2	GND	—	Signal and power ground pin. Place the bottom resistor of the feedback network as close as possible to this pin.
3	FB	I	Feedback pin. Connect FB to the LED string cathode and an external resistor to ground to set the LED current.
4	EN/DIM	I	Enable control input. Logic high enables operation. Toggling this pin with a periodic logic square wave of varying duty cycle at different frequencies controls the brightness of LEDs. Do not allow this pin to float or be greater than $V_{IN} + 0.3\text{ V}$.
5	VIN	I	Input supply voltage. Connect a bypass capacitor locally from this pin to GND.
6	SW	O	Switch pin. Connect this pin to the inductor, catch diode, and bootstrap capacitor.

7 Detailed Description

7.1 Overview

The LM3405 device is a PWM, current-mode controlled buck switching regulator designed to provide a simple, high efficiency solution for driving LEDs with a preset switching frequency of 1.6MHz. This high frequency allows the LM3405 to operate with small surface mount capacitors and inductors, resulting in LED drivers that only require a minimum amount of board space. The LM3405 is internally compensated, simple to use, and requires few external components.

The following sections refer to [Functional Block Diagram](#) and to the waveforms in [Figure 11](#). The LM3405 supplies a regulated output current by switching the internal NMOS power switch at constant frequency and variable duty cycle. A switching cycle begins at the falling edge of the reset pulse generated by the internal oscillator. When this pulse goes low, the output control logic turns on the internal NMOS power switch. During this on-time, the SW pin voltage (V_{SW}) swings up to approximately V_{IN} , and the inductor current (I_L) increases with a linear slope. I_L is measured by the current sense amplifier, which generates an output proportional to the switch current. The sense signal is summed with the regulator's corrective ramp and compared to the error amplifier's output, which is proportional to the difference between the feedback voltage and V_{REF} . When the PWM comparator output goes high, the internal power switch turns off until the next switching cycle begins. During the switch off-time, inductor current discharges through the catch diode D1, which forces the SW pin to swing below ground by the forward voltage (V_{D1}) of the catch diode. The regulator loop adjusts the duty cycle (D) to maintain a constant output current (I_F) through the LED, by forcing FB pin voltage to be equal to V_{REF} (0.205 V).

7.3 Feature Description

7.3.1 Boost Function

Capacitor C3 and diode D2 in the [Functional Block Diagram](#) are used to generate a voltage V_{BOOST} . The voltage across C3, $V_{BOOST} - V_{SW}$, is the gate drive voltage to the internal NMOS power switch. To properly drive the internal NMOS switch during its on-time, V_{BOOST} must be at least 2.5-V greater than V_{SW} . TI recommends a large value of $V_{BOOST} - V_{SW}$ to achieve better efficiency by minimizing both the internal switch ON resistance ($R_{DS(ON)}$) and the switch rise and fall times. However, $V_{BOOST} - V_{SW}$ must not exceed the maximum operating limit of 5.5 V.

When the LM3405 starts up, internal circuitry from V_{IN} supplies a 20-mA current to the BOOST pin, flowing out of the BOOST pin into C3. This current charges C3 to a voltage sufficient to turn the switch on. The BOOST pin continues to source current to C3 until the voltage at the feedback pin is greater than 123 mV.

There are various methods to derive V_{BOOST} :

1. From the input voltage (V_{IN})
2. From the output voltage (V_{OUT})
3. From a shunt or series Zener diode
4. From an external distributed voltage rail (V_{EXT})

The first method is shown in [Functional Block Diagram](#). Capacitor C3 is charged through diode D2 by V_{IN} . During a normal switching cycle, when the internal NMOS power switch is off, T_{OFF} (see [Figure 11](#)), V_{BOOST} equals V_{IN} minus the forward voltage of D2 (V_{D2}), during which the current in the inductor ($L1$) forward biases the catch diode D1 (V_{D1}). Therefore, the gate drive voltage stored across C3 is shown in [Equation 1](#).

$$V_{BOOST} - V_{SW} = V_{IN} - V_{D2} + V_{D1} \quad (1)$$

When the NMOS switch turns on (T_{ON}), the switch pin rises to [Equation 2](#).

$$V_{SW} = V_{IN} - (R_{DS(ON)} \times I_L) \quad (2)$$

Because the voltage across C3 remains unchanged, V_{BOOST} is forced to rise thus reverse biasing D2. The voltage at V_{BOOST} is then calculated with [Equation 3](#).

Feature Description (continued)

$$V_{\text{BOOST}} = 2V_{\text{IN}} - (R_{\text{DS(ON)}} \times I_{\text{L}}) - V_{\text{D2}} + V_{\text{D1}} \quad (3)$$

Depending on the quality of the diodes D1 and D2, the gate drive voltage in this method can be slightly less or larger than the input voltage V_{IN} . For best performance, ensure that the variation of the input supply does not cause the gate drive voltage to fall outside the recommended range in [Equation 4](#).

$$2.5 \text{ V} < V_{\text{IN}} - V_{\text{D2}} + V_{\text{D1}} < 5.5 \text{ V} \quad (4)$$

The second method for deriving the boost voltage is to connect D2 to the output as shown in [Figure 12](#). The gate drive voltage in this configuration is shown in [Equation 5](#).

$$V_{\text{BOOST}} - V_{\text{SW}} = V_{\text{OUT}} - V_{\text{D2}} + V_{\text{D1}} \quad (5)$$

Because the gate drive voltage must be in the range of 2.5 V to 5.5 V, the output voltage V_{OUT} must be limited to a certain range. For the calculation of V_{OUT} , see [Output Voltage](#).

Copyright © 2016, Texas Instruments Incorporated

Figure 12. V_{BOOST} Derived from V_{OUT}

The third method can be used in the applications where both V_{IN} and V_{OUT} are greater than 5.5 V. In these cases, C3 cannot be charged directly from these voltages; instead C3 can be charged from V_{IN} or V_{OUT} minus a Zener voltage (V_{D3}) by placing a Zener diode D3 in series with D2 as shown in [Figure 13](#). When using a series Zener diode from the input, the gate drive voltage is $V_{\text{IN}} - V_{\text{D3}} - V_{\text{D2}} + V_{\text{D1}}$.

Copyright © 2016, Texas Instruments Incorporated

Figure 13. V_{BOOST} Derived from V_{IN} Through a Series Zener

Feature Description (continued)

An alternate method is to place the Zener diode D3 in a shunt configuration as shown in [Figure 14](#). A small, 350-mW to 500-mW, 5.1-V Zener in a SOT or SOD package can be used for this purpose. A small ceramic capacitor such as a 6.3-V, 0.1-μF capacitor (C5) must be placed in parallel with the Zener diode. When the internal NMOS switch turns on, a pulse of current is drawn to charge the internal NMOS gate capacitance. The 0.1-μF parallel shunt capacitor ensures that the V_{BOOST} voltage is maintained during this time. Resistor R2 must be chosen to provide enough RMS current to the Zener diode and to the BOOST pin. TI's recommended choice for the Zener current (I_{ZENER}) is 1 mA. The current I_{BOOST} into the BOOST pin supplies the gate current of the NMOS power switch. It reaches a maximum of around 3.6 mA at the highest gate drive voltage of 5.5 V over the LM3405 operating range.

For the worst case I_{BOOST} , increase the current by 50%. In that case, the maximum boost current is [Equation 6](#).

$$I_{\text{BOOST-MAX}} = 1.5 \times 3.6 \text{ mA} = 5.4 \text{ mA} \quad (6)$$

R2 is calculated with [Equation 7](#).

$$R2 = (V_{\text{IN}} - V_{\text{ZENER}}) / (I_{\text{BOOST-MAX}} + I_{\text{ZENER}}) \quad (7)$$

For example, let $V_{\text{IN}} = 12 \text{ V}$, $V_{\text{ZENER}} = 5 \text{ V}$, $I_{\text{ZENER}} = 1 \text{ mA}$, then calculate [Equation 8](#).

$$R2 = (12 \text{ V} - 5 \text{ V}) / (5.4 \text{ mA} + 1 \text{ mA}) = 1.09 \text{ k}\Omega \quad (8)$$

Copyright © 2016, Texas Instruments Incorporated

Figure 14. V_{BOOST} Derived from V_{IN} Through a Shunt Zener

The fourth method can be used in an application which has an external low voltage rail, V_{EXT} . C3 can be charged through D2 from V_{EXT} , independent of V_{IN} and V_{OUT} voltage levels. Again for best performance, ensure that the gate drive voltage, $V_{\text{EXT}} - V_{\text{D2}} + V_{\text{D1}}$, falls in the range of 2.5 V to 5.5 V.

7.3.2 Setting the LED Current

LM3405 is a constant current buck regulator. The LEDs are connected between V_{OUT} and the FB pin as shown in the [Typical Applications](#). The FB pin is at 0.205 V in regulation and therefore the LED current I_{F} is set by V_{FB} and resistor R1 from FB to ground by [Equation 9](#).

$$I_{\text{F}} = V_{\text{FB}} / R1 \quad (9)$$

I_{F} must not exceed the 1-A current capability of LM3405 and, therefore, R1 minimum must be approximately 0.2 Ω. I_{F} must also be kept above 200 mA for stable operation, and therefore R1 maximum must be approximately 1 Ω. If average LED currents less than 200 mA are desired, the EN/DIM pin can be used for PWM dimming. See [LED PWM Dimming](#).

Feature Description (continued)

7.3.3 Output Voltage

The output voltage is primarily determined by the number of LEDs (n) connected from V_{OUT} to FB pin and therefore V_{OUT} can be calculated with [Equation 10](#).

$$V_{OUT} = ((n \times V_F) + V_{FB})$$

where

- V_F is the forward voltage of one LED at the set LED current level (see LED manufacturer data sheet for forward characteristics curve) (10)

7.3.4 Enable Mode or Shutdown Mode

The LM3405 has both enable and shutdown modes that are controlled by the EN/DIM pin. Connecting a voltage source greater than 1.8 V to the EN/DIM pin enables the operation of LM3405, while reducing this voltage below 0.4 V places the part in a low quiescent current (0.3 μ A typical) shutdown mode. There is no internal pullup on EN/DIM pin, therefore an external signal is required to initiate switching. Do not allow this pin to float or rise to 0.3 V above V_{IN} . It must be noted that when the EN/DIM pin voltage rises above 1.8 V while the input voltage is greater than UVLO, there is a finite delay before switching starts. During this delay, the LM3405 goes through a power on reset state after which the internal soft-start process commences. The soft-start process limits the inrush current and brings up the LED current (I_F) in a smooth and controlled fashion. The total combined duration of the power on reset delay, soft-start delay and the delay to fully establish the LED current is in the order of 100 μ s (see [Figure 19](#)).

The simplest way to enable the operation of LM3405 is to connect the EN/DIM pin to V_{IN} which allows self start-up of LM3405 whenever the input voltage is applied. However, when an input voltage of slow rise time is used to power the application and if both the input voltage and the output voltage are not fully established before the soft-start time elapses, the control circuit commands maximum duty cycle operation of the internal power switch to bring up the output voltage rapidly. When the feedback pin voltage exceeds 0.205 V, the duty cycle has to reduce from the maximum value accordingly, to maintain regulation. It takes a finite amount of time for this reduction of duty cycle and this results in a spike in LED current for a short duration as shown in [Figure 15](#). In applications where this LED current overshoot is undesirable, EN/DIM pin voltage can be separately applied and delayed such that V_{IN} is fully established before the EN/DIM pin voltage reaches the enable threshold. The effect of delaying EN/DIM with respect to V_{IN} on the LED current is shown in [Figure 16](#). For a fast rising input voltage (200 μ s for example), there is no need to delay the EN/DIM signal, because soft-start can smoothly bring up the LED current as shown in [Figure 17](#).

Feature Description (continued)

Figure 17. Start-Up Response to V_{IN} With 200- μ s Rise Time

7.3.5 LED PWM Dimming

The LED brightness can be controlled by applying a periodic pulse signal to the EN/DIM pin and varying its frequency and/or duty cycle. This so-called PWM dimming method controls the average light output by pulsing the LED current between the set value and zero. A logic high level at the EN/DIM pin turns on the LED current whereas a logic low level turns off the LED current. Figure 18 shows a typical LED current waveform in PWM dimming mode. As explained in the previous section, there is approximately a 100- μ s delay from the EN/DIM signal going high to fully establishing the LED current as shown in Figure 19. This 100- μ s delay sets a maximum frequency limit for the driving signal that can be applied to the EN/DIM pin for PWM dimming. Figure 20 shows the average LED current versus duty cycle of PWM dimming signal for various frequencies. The applicable frequency range to drive LM3405 for PWM dimming is from 100 Hz to 5 kHz. The dimming ratio reduces drastically when the applied PWM dimming frequency is greater than 5 kHz.

Figure 18. PWM Dimming of LEDs Using the EN/DIM Pin

Figure 19. Start-Up Response to EN/DIM With $I_F = 1$ A

Feature Description (continued)

Figure 20. Average LED Current vs Duty Cycle of PWM Dimming Signal at EN/DIM Pin

7.3.6 Undervoltage Lockout

Undervoltage lockout (UVLO) prevents the LM3405 from operating until the input voltage exceeds 2.74 V (typical). The UVLO threshold has approximately 440 mV of hysteresis, so the part operates until V_{IN} drops below 2.3 V (typical). Hysteresis prevents the part from turning off during power up if V_{IN} is non-monotonic.

7.3.7 Current Limit

The LM3405 uses cycle-by-cycle current limit to protect the internal power switch. During each switching cycle, a current limit comparator detects if the power switch current exceeds 2 A (typical), and turns off the switch until the next switching cycle begins.

7.3.8 Overcurrent Protection

The LM3405 has a built-in overcurrent comparator that compares the FB pin voltage to a threshold voltage that is 60% higher than the internal reference V_{REF} . Once the FB pin voltage exceeds this threshold level (typically 328 mV), the internal NMOS power switch is turned off, which allows the feedback voltage to decrease towards regulation. This threshold provides an upper limit for the LED current. LED current overshoot is limited to 328 mV/R1 by this comparator during transients.

7.4 Device Functional Modes

7.4.1 Thermal Shutdown

Thermal shutdown limits total power dissipation by turning off the internal power switch when the IC junction temperature exceeds 165°C. After thermal shutdown occurs, the power switch does not turn on until the junction temperature drops below approximately 150°C.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Inductor (L1)

The duty cycle (D) can be approximated quickly using the ratio of output voltage (V_{OUT}) to input voltage (V_{IN}) in [Equation 11](#).

$$D = \frac{V_{OUT}}{V_{IN}} \quad (11)$$

The catch diode (D1) forward voltage drop and the voltage drop across the internal NMOS must be included to calculate a more accurate duty cycle. Calculate D by using [Equation 12](#).

$$D = \frac{V_{OUT} + V_{D1}}{V_{IN} + V_{D1} - V_{SW}} \quad (12)$$

V_{SW} can be approximated by [Equation 13](#).

$$V_{SW} = I_F \times R_{DS(ON)} \quad (13)$$

The diode forward drop (V_{D1}) can range from 0.3 V to 0.7 V depending on the quality of the diode. The lower V_{D1} is, the higher the operating efficiency of the converter.

The inductor value determines the output ripple current (Δi_L , as defined in [Figure 11](#)). Lower inductor values decrease the size of the inductor, but increases the output ripple current. An increase in the inductor value decreases the output ripple current. The ratio of ripple current to LED current is optimized when it is set between 0.3 and 0.4 at 1A LED current. This ratio r is defined as:

$$r = \frac{\Delta i_L}{I_F} \quad (14)$$

One must also ensure that the minimum current limit (1.2 A) is not exceeded, so the peak current in the inductor must be calculated. The peak current (I_{LPK}) in the inductor is calculated with [Equation 15](#).

$$I_{LPK} = I_F + \Delta i_L / 2 \quad (15)$$

When the designed maximum output current is reduced, the ratio (r) can be increased. At a current of 0.2 A, r can be made as high as 0.7. The ripple ratio can be increased at lighter loads because the net ripple is actually quite low, and if r remains constant the inductor value can be made quite large. An equation empirically developed for the maximum ripple ratio at any current below 2 A is calculated with [Equation 16](#) (note that this is just a guideline).

$$r = 0.387 \times I_{OUT}^{-0.3667} \quad (16)$$

The LM3405 operates at a high frequency allowing the use of ceramic output capacitors without compromising transient response. Ceramic capacitors allow higher inductor ripple without significantly increasing LED current ripple. See the output capacitor and feed-forward capacitor sections for more details on LED current ripple.

Now that the ripple current or ripple ratio is determined, the inductance is calculated by [Equation 17](#).

$$L = \frac{V_{OUT} + V_{D1}}{I_F \times r \times f_{SW}} \times (1-D)$$

where

- f_{SW} is the switching frequency
- I_F is the LED current

(17)

Application Information (continued)

When selecting an inductor, make sure that it is capable of supporting the peak output current without saturating. Inductor saturation results in a sudden reduction in inductance and prevent the regulator from operating correctly. Because of the operating frequency of the LM3405, ferrite based inductors are preferred to minimize core losses. This presents little restriction, because the variety of ferrite based inductors is huge. Lastly, inductors with lower series resistance (DCR) provides better operating efficiency. For recommended inductor selection, see *Circuit Examples and Recommended Inductance Range* in [Table 1](#).

Table 1. Recommended Inductance Range

I_F	INDUCTANCE RANGE AND INDUCTOR CURRENT RIPPLE			
1 A	4.7 μH TO 10 μH			
	Inductance	4.7 μ H	6.8 μ H	10 μ H
	$\Delta i_L / I_F^{(1)}$	51%	35%	24%
0.6 A	6.8 μH TO 15 μH			
	Inductance	6.8 μ H	10 μ H	15 μ H
	$\Delta i_L / I_F^{(1)}$	58%	40%	26%
0.2 A	4.7 μH⁽²⁾ TO 22 μH			
	Inductance	10 μ H	15 μ H	22 μ H
	$\Delta i_L / I_F^{(1)}$	119%	79%	54%

(1) Maximum over full range of V_{IN} and V_{OUT} .

(2) Small inductance improves stability without causing a significant increase in LED current ripple.

8.1.2 Input Capacitor (C1)

An input capacitor is necessary to ensure that V_{IN} does not drop excessively during switching transients. The primary specifications of the input capacitor are capacitance, voltage rating, RMS current rating, and ESL (Equivalent Series Inductance). The input voltage rating is specifically stated by the capacitor manufacturer. Check any recommended deratings and also verify if there is any significant change in capacitance at the operating input voltage and the operating temperature. The input capacitor maximum RMS input current rating (I_{RMS-IN}) must be greater than [Equation 18](#).

$$I_{RMS-IN} = I_F \times \sqrt{D \times \left(1 - D + \frac{r^2}{12}\right)} \quad (18)$$

[Equation 18](#) shows that maximum RMS capacitor current occurs when $D = 0.5$. Always calculate the RMS at the point where the duty cycle D , is closest to 0.5. The ESL of an input capacitor is usually determined by the effective cross sectional area of the current path. A large-leaded capacitor has high ESL and an 0805 ceramic chip capacitor has very low ESL. At the operating frequency of the LM3405, certain capacitors may have an ESL so large that the resulting inductive impedance ($2\pi fL$) is higher than that required to provide stable operation. TI strongly recommends using ceramic capacitors due to their low ESR and low ESL. A 10- μ F multilayer ceramic capacitor (MLCC) is a good choice for most applications. In cases where large capacitance is required, use surface mount capacitors such as Tantalum capacitors and place at least a 1- μ F ceramic capacitor close to the V_{IN} pin. For MLCCs, TI recommends using X7R or X5R dielectrics. Consult capacitor manufacturer datasheet to see how rated capacitance varies over operating conditions.

8.1.3 Output Capacitor (C2)

The output capacitor is selected based upon the desired reduction in LED current ripple. A 1- μ F ceramic capacitor results in very low LED current ripple for most applications. Due to the high switching frequency, the 1- μ F capacitor alone (without feed-forward capacitor C4) can filter more than 90% of the inductor current ripple for most applications where the sum of LED dynamic resistance and R1 is larger than 1 Ω . Because the internal compensation is tailored for small output capacitance with very low ESR, TI strongly recommends using a ceramic capacitor with capacitance less than 3.3 μ F.

Given the availability and quality of MLCCs and the expected output voltage of designs using the LM3405, there is really no need to review other capacitor technologies. A benefit of ceramic capacitors is their ability to bypass high frequency noise. A certain amount of switching edge noise couples through the parasitic capacitances in the inductor to the output. A ceramic capacitor bypasses this noise. In cases where large capacitance is required, use Electrolytic or Tantalum capacitors with large ESR, and verify the loop performance on the bench. Like the input capacitor, multilayer ceramic capacitors are recommended X7R or X5R. Again, verify actual capacitance at the desired operating voltage and temperature.

Check the RMS current rating of the capacitor. The maximum RMS current rating of the capacitor is calculated with Equation 19.

$$I_{\text{RMS-OUT}} = I_F \times \frac{r}{\sqrt{12}} \quad (19)$$

One may select a 1206 size ceramic capacitor for C2, because its current rating is typically higher than 1 A, more than enough for the requirement.

8.1.4 Feed-Forward Capacitor (C4)

The feed-forward capacitor (designated as C4) connected in parallel with the LED string is required to provide multiple benefits to the LED driver design. It greatly improves the large signal transient response and suppresses LED current overshoot that may otherwise occur during PWM dimming; it also helps to shape the rise and fall times of the LED current pulse during PWM dimming thus reducing EMI emission; it reduces LED current ripple by bypassing some of inductor ripple from flowing through the LED. For most applications, a 1-μF ceramic capacitor is sufficient. In fact, the combination of a 1-μF feed-forward ceramic capacitor and a 1-μF output ceramic capacitor leads to less than 1% current ripple flowing through the LED. Lower and higher C4 values can be used, but bench validation is required to ensure the performance meets the application requirement.

Figure 21 shows a typical LED current waveform during PWM dimming without feed-forward capacitor. At the beginning of each PWM cycle, overshoot can be seen in the LED current. Adding a 1-μF feed-forward capacitor can totally remove the overshoot as shown in Figure 22.

Figure 21. PWM Dimming Without Feed-Forward Capacitor

Figure 22. PWM Dimming With a 1-μF Feed-Forward Capacitor

8.1.5 Catch Diode (D1)

The catch diode (D1) conducts during the switch off-time. A Schottky diode is required for its fast switching time and low forward voltage drop. The catch diode must be chosen such that its current rating is greater than Equation 20.

$$I_{D1} = I_F \times (1-D) \quad (20)$$

The reverse breakdown rating of the diode must be at least the maximum input voltage plus appropriate margin. To improve efficiency, choose a Schottky diode with a low forward voltage drop.

8.1.6 Boost Diode (D2)

TI recommends a standard diode such as the 1N4148 type. For V_{BOOST} circuits derived from voltages less than 3.3 V, a small-signal Schottky diode is recommended for better efficiency. A good choice is the BAT54 small signal diode.

8.1.7 Boost Capacitor (C3)

A 0.01- μF ceramic capacitor with a voltage rating of at least 6.3 V is sufficient. The X7R and X5R MLCCs provide the best performance.

8.1.8 Power Loss Estimation

The main power loss in LM3405 includes three basic types of loss in the internal power switch: conduction loss, switching loss, and gate charge loss. In addition, there is loss associated with the power required for the internal circuitry of IC.

The conduction loss is calculated with [Equation 21](#).

$$P_{\text{COND}} = \left(I_F^2 \times D \right) \times \left(1 + \frac{1}{3} \times \left(\frac{\Delta I_L}{I_F} \right)^2 \right) \times R_{\text{DS(ON)}} \quad (21)$$

If the inductor ripple current is fairly small (for example, less than 40%), the conduction loss can be simplified with [Equation 22](#).

$$P_{\text{COND}} = I_F^2 \times R_{\text{DS(ON)}} \times D \quad (22)$$

The switching loss occurs during the switch on and off transition periods, where voltage and current overlap resulting in power loss. The simplest means to determine this loss is to empirically measure the rise and fall times (10% to 90%) of the voltage at the switch pin.

Switching power loss is calculated with [Equation 23](#).

$$P_{\text{SW}} = 0.5 \times V_{\text{IN}} \times I_F \times f_{\text{SW}} \times (T_{\text{RISE}} + T_{\text{FALL}}) \quad (23)$$

The gate charge loss is associated with the gate charge Q_G required to drive the switch with [Equation 24](#).

$$P_G = f_{\text{SW}} \times V_{\text{IN}} \times Q_G \quad (24)$$

The power loss required for operation of the internal circuitry is calculated with [Equation 25](#).

$$P_Q = I_Q \times V_{\text{IN}} \quad (25)$$

I_Q is the quiescent operating current, and is typically around 1.8mA for the LM3405.

The total power loss in the IC is [Equation 26](#).

$$P_{\text{INTERNAL}} = P_{\text{COND}} + P_{\text{SW}} + P_G + P_Q \quad (26)$$

An example of power losses for a typical application is shown in [Table 2](#), [Equation 27](#), and [Equation 28](#) (D is calculated to be 0.36).

Table 2. Power Loss Tabulation

CONDITIONS		POWER LOSS	
V_{IN}	12 V	—	—
V_{OUT}	3.9 V	—	—
I_{OUT}	1 A	—	—
V_{D1}	0.45 V	—	—
$R_{\text{DS(ON)}}$	300 m Ω	P_{COND}	111 mW
f_{SW}	1.6 MHz	—	—
T_{RISE}	18 ns	P_{SW}	288 mW
T_{FALL}	12 ns		
I_Q	1.8 mA	P_Q	22 mW
Q_G	1.4 nC	P_G	27 mW

Typical Applications (continued)

8.2.1.2.3 Set the Nominal LED Current (R1)

The nominal LED current at 100% PWM dimming duty cycle is set by the resistor R1. R1 can be calculated using [Equation 30](#).

$$R1 = \frac{V_{FB}}{I_F} = \frac{0.205V}{1A} = 0.205\Omega \quad (30)$$

The standard value of R1 = 0.2 Ω is chosen. R1 must have a power rating of at least 1/4 W.

8.2.1.2.4 Choose Diodes (D1 and D2)

For the boost diode, D2, choose a low current diode with a voltage rating greater than the input voltage to give some margin. D2 must also be a schottky to minimize the forward voltage drop. For this example a schottky diode of D2 = 100 mA, 30 V is chosen. The catch diode, D1, must be a schottky diode and must have a voltage rating greater than the input voltage and a current rating greater than the average current. The average current in D1 can be calculated with [Equation 31](#).

$$I_{D1} = I_F \times (1 - D) = 1A \times (1 - 0.72) = 0.28A \quad (31)$$

For this example D1 = 1 A, 10 V is chosen.

8.2.1.2.5 Calculate the Inductor Value (L1)

The inductor value is chosen for a given ripple ratio (r). To calculate L1 the forward voltage of D1 is required. In this case the chosen diode has a forward voltage drop of $V_F = 0.37$ V. Given the desired ripple ratio L1 is calculated with [Equation 32](#).

$$L = \frac{V_{OUT} + V_{D1}}{I_F \times r \times f_{SW}} = \frac{3.6V + 0.37V}{1A \times 0.6 \times 1.6MHz} = 4.14\mu H \quad (32)$$

The next larger standard value of L1 = 4.7 μ H is chosen. A ripple ratio of 0.6 translates to a Δi_L of 600 mA and a peak inductor current of 1.3 A ($I_F + \Delta i_L/2$). Choose an inductor with a saturation current rating of greater than 1.3 A.

9 Power Supply Recommendations

Any DC output power supply may be used provided it has a high enough voltage and current rating required for the particular application.

10 Layout

10.1 Layout Guidelines

When planning the layout there are a few things to consider when trying to achieve a clean, regulated output. The most important consideration when completing the layout is the close coupling of the GND connections of the input capacitor C1 and the catch diode D1. These ground ends must be close to one another and be connected to the GND plane with at least two vias. Place these components as close to the IC as possible. The next consideration is the location of the GND connection of the output capacitor C2, which must be near the GND connections of C1 and D1.

There must be a continuous ground plane on the bottom layer of a two-layer board.

The FB pin is a high impedance node and take care to make the FB trace short to avoid noise pickup that causes inaccurate regulation. The LED current setting resistor R1 must be placed as close as possible to the IC, with the GND of R1 placed as close as possible to the GND of the IC. The V_{OUT} trace to LED anode must be routed away from the inductor and any other traces that are switching.

High AC currents flow through the V_{IN} , SW and V_{OUT} traces, so they must be as short and wide as possible. Radiated noise can be decreased by choosing a shielded inductor.

The remaining components must also be placed as close as possible to the IC. See [AN-1229 SIMPLE SWITCHER® PCB Layout Guidelines](#) (SNVA054) for further considerations.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.
