

# 3-Axis Digital Compass IC

## HMC5843

The Honeywell HMC5843 is a surface mount multi-chip module designed for low field magnetic sensing with a digital interface for applications such as low cost compassing and magnetometry. The HMC5843 includes our state of the art 1043 series magneto-resistive sensors plus Honeywell developed ASIC containing amplification, strap drivers, offset cancellation, 12-bit ADC and an I<sup>2</sup>C serial bus interface. The HMC5843 is in a 4.0 by 4.0 by 1.3mm surface mount leadless chip carrier (LCC). Applications for the HMC5843 include Consumer Electronics, Auto Navigation Systems, Personal Navigation Devices, and Magnetometers.

The HMC5843 utilizes Honeywell's Anisotropic Magnetoresistive (AMR) technology that provides advantages over other magnetic sensor technologies. The sensors feature precision in-axis sensitivity and linearity, solid-state construction with very low cross-axis sensitivity designed to measure both direction and magnitude of Earth's magnetic fields, from tens of micro-gauss to 6 gauss. Honeywell's Magnetic Sensors are among the most sensitive and reliable low-field sensors in the industry.

Honeywell continues to maintain product excellence and performance by introducing innovative solid-state magnetic sensor solutions. These are highly reliable, top performance products that are delivered when promised. Honeywell's magnetic sensor solutions provide real solutions you can count on.

### FEATURES

- ▶ 3-Axis Magnetoresistive Sensors and ASIC in a Single Package
- ▶ Low Cost
- ▶ 4.0 x 4.0 x 1.3mm Low Height Profile LCC Surface Mount Package
- ▶ Low Voltage Operations (2.5 to 3.3V)
- ▶ Built-In Strap Drive Circuits
- ▶ I<sup>2</sup>C Digital Interface
- ▶ Lead Free Package Construction
- ▶ Wide Magnetic Field Range (+/-6 Oe)
- ▶ Available in Tape & Reel Packaging
- ▶ Fast 116 Hz Maximum Output Rate

### BENEFITS

- ▶ Small Size for Highly Integrated Products. Just Add a Micro-Controller Interface, Plus Two External SMT Capacitors
- ▶ Designed for High Volume, Cost Sensitive OEM Designs
- ▶ Easy to Assemble & Compatible with High Speed SMT Assembly
- ▶ Compatible for Battery Powered Applications
- ▶ Set/Reset and Offset Strap Drivers for Degaussing, Self Test, and Offset Compensation
- ▶ Popular Two-Wire Serial Data Interface for Consumer Electronics
- ▶ Complies with Current Environmental Standards
- ▶ Sensors Can Be Used in Strong Magnetic Field Environments
- ▶ High Volume OEM Assembly
- ▶ Enables Pedestrian Navigation and LBS Applications

# HMC5843

## SPECIFICATIONS (\* Tested at 25°C except stated otherwise.)

Characteristics	Conditions*	Min	Typ	Max	Units
<b>Power Supply</b>

## MOUNTING CONSIDERATIONS

The following is the recommend printed circuit board (PCB) footprint for the HMC5843.

### PCB Pad Definition and Traces

The HMC5843 is a fine pitch LCC package with a 0.50mm pin pitch (spacing), with the pin pads defined as 0.40mm by 0.25mm in size. PCB pads are recommended to be oversized by 0.025mm from each pad for a short dimension oversize of 0.05mm. The interior PCB pad is recommended to be 0.05mm oversized per pin with an exterior oversize of 0.20mm for proper package centering and to permit test probing. Size the traces between the HMC5843 and the external capacitors (C1 and C2) to handle the 1 ampere peak current pulses with low voltage drop on the traces.

### Stencil Design and Solder Paste

A 4 mil stencil and 100% paste coverage is recommended for the electrical contact pads.

### Pick and Place

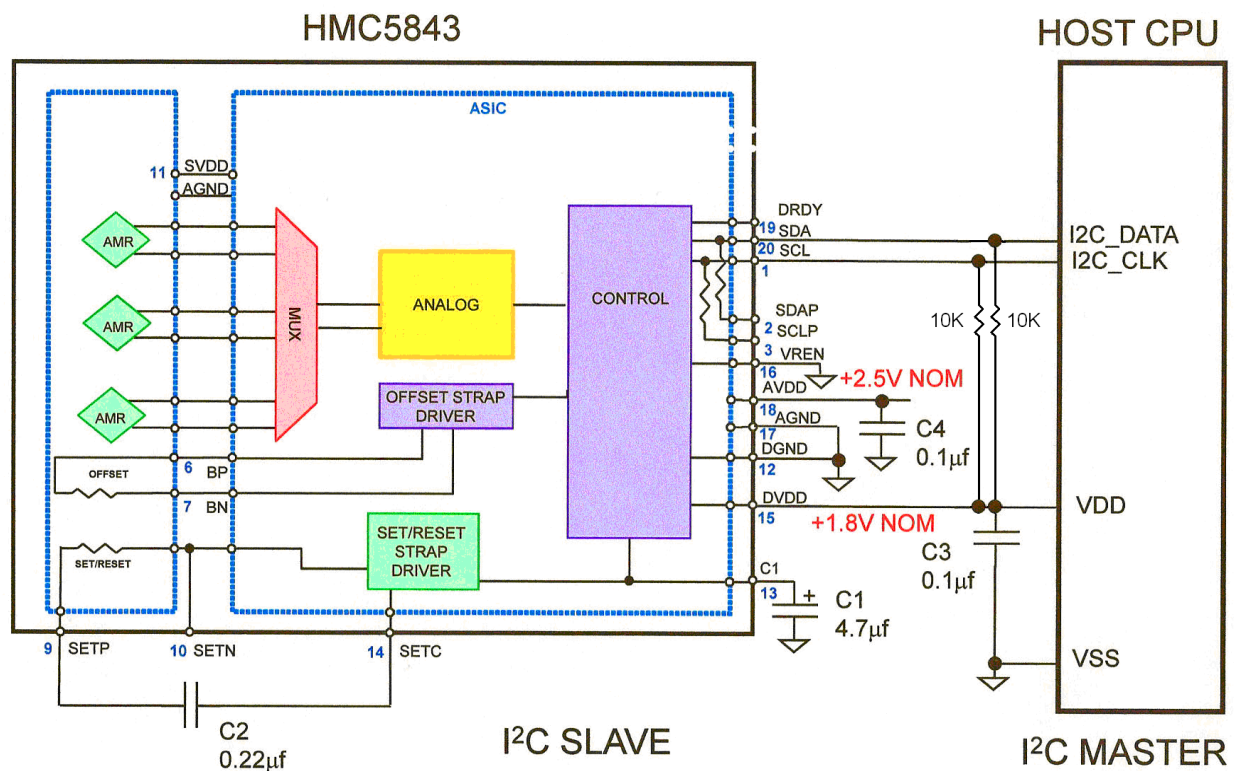

Placement is machine dependant and no restrictions are recommended, and have been tested with mechanical centering. Placement force should be equivalent 1206 SMT resistors and enough force should be used to squeeze the paste out from the package/contact pad overlap and to keep the package pin contacts vertical.

### Reflow and Rework

This device is classified as MSL 3 with 260 °C peak reflow temperature. A baking process (125 °C, 24 hrs) is required if device is not kept continuously in a dry (< 10% RH) environment before assembly. No special profile is required for the HMC5843 and compatible with lead eutectic and lead-free solder paste reflow profiles. Honeywell recommends the adherence to solder paste manufacturer's guidelines. The HMC5843 may be reworked with soldering irons, but extreme care must be taken not to overheat the copper pads from the part's fiberglass substrate. Irons with a tip temperature no greater than 315°C should be used. Excessive rework risks the copper pads pulling away into the molten solder.

### Typical Measurement Period in Single-Measurement Mode

# HMC5843

## BASIC DEVICE OPERATION

### Anisotropic Magneto-Resistive Sensors

The Honeywell HMC5843 magnetoresistive sensor circuit is a trio of sensors and application specific support circuits to measure magnetic fields. With power supply applied, the sensor converts any incident magnetic field in the sensitive axis directions to a differential voltage output. The magnetoresistive sensors are made of a nickel-iron (Permalloy) thin-film and patterned as a resistive strip element. In the presence of a magnetic field, a change in the bridge resistive elements causes a corresponding change in voltage across the bridge outputs.

These resistive elements are aligned together to have a common sensitive axis (indicated by arrows on the pinouts) that will provide positive voltage change with magnetic fields increasing in the sensitive direction. Because the output only is in proportion to the one-dimensional axis (the principle of anisotropy) and its magnitude, additional sensor bridges placed at orthogonal directions permit accurate measurement of arbitrary field direction.

### Self Test

An offset strap is designed for self test function. The offset strap measures nominally 13 ohms, and requires 10mA for each gauss of induced field. The straps will easily handle currents to buck or boost fields through the  $\pm 4$  gauss linear measurement range, but designers should note the extreme thermal heating on the sensor die when doing so. See SELF TEST OPERATION section below.

### Power Management

This device is capable of operating with a single supply (AVDD) or dual supplies (AVDD and DVDD). Pin VREN makes this selection by enabling the internal digital supply voltage regulator. When VREN is tied to AVDD, the device is in single supply operation; this device is powered from AVDD; and the internal voltage regulator is enabled. When VREN is tied to AGND this device operates with both AVDD and DVDD as supplies. The table below shows the modes available at the various power supply conditions.

DVDD	AVDD	Pin VREN	Modes Supported	Description
High	High	AGND	All	Internal voltage regulator: Disabled. Digital I/O pins: Range from DGND to DVDD. Device fully functional. Digital logic blocks are powered from DVDD supply, including all on-board clocks.
High	Low	AGND	Idle, Sleep	Internal voltage regulator: Disabled. Digital I/O pins: Range from DGND to DVDD. Device Measurement functionality not supported. Device I <sup>2</sup> C bus and register access supported.
Internally regulated	High	AVDD	All	Internal voltage regulator: Enabled Digital I/O pins: Range from AGND to AVDD Device fully functional. Digital logic blocks are powered through on-board regulator.

Table 2: Operational Modes and Supply States

### Voltage Regulator

This ASIC has an internal voltage regulator which, depending on the application needs, may be used instead of supplying voltage to pin DVDD. If DVDD pin is used, the internal voltage regulator is not engaged. When both supplies are used, DVDD is typically high before AVDD, but no latch-up conditions will exist if DVDD is brought high after AVDD.

# HMC5843

## Power on Reset

Power on reset (POR) circuit shall return the device to the power-on default state. All registers shall be returned to their default values. Circuitry shall return to its default state, such as, but not limited to: MUX channel, ADC state machine, and bias current.

## I<sup>2</sup>C Interface

Control of this device is carried out via the I<sup>2</sup>C bus. This device will be connected to this bus as a slave device under the control of a master device, such as the processor.

This device shall be compliant with *I<sup>2</sup>C-Bus Specification*, document number: 9398 393 40011. As an I<sup>2</sup>C compatible device, this device has a 7-bit serial address and supports I<sup>2</sup>C protocols. This device shall support standard and fast modes, 100kHz and 400kHz respectively, but cannot support the high speed mode (Hs). External pull-up resistors are required to support these standard and fast speed modes. Depending on the application, the internal pull-ups may be used to support slower data speeds than specified by I<sup>2</sup>C standards. This device does not contain 50nsec spike suppression as required by fast mode operation in the I<sup>2</sup>C-Bus Specification, "Table 4 Characteristics of the SDA and SCL I/O stages for F/S-mode I<sup>2</sup>C-bus devices".

Activities required by the master (register read and write) have priority over internal activities, such as the measurement. The purpose of this priority is to not keep the master waiting and the I<sup>2</sup>C bus engaged for longer than necessary.

## I<sup>2</sup>C Pull-up Resistors

Pull-up resistors are placed on the two I<sup>2</sup>C bus lines. Typically these resistors are off-chip, but, to conserve board space in specific low clock speed applications, they are internal to this device.

## Internal Clock

The device has an internal clock for internal digital logic functions and timing management.

## H-Bridge for Set/Reset Strap Drive

The ASIC contains large switching FETs capable of delivering a large but brief pulse to the Set / Reset strap of the sensor. This strap is largely a resistive load.

## Charge Current Limit

The current that reservoir capacitor (C1) can draw when charging is limited. When using dual supplies this device shall limit the current drawn from DVDD source to charge this capacitor. When only a single supply is used, Pin DVDD is externally tied to pin C1. In this configuration, current is still limited. For example, the internal voltage regulator will limit this current draw.

## Bias Current Generator

The bias current generator is used to apply a bias current to the offset strap of the magneto-resistive sensor, which creates an artificial magnetic field bias on the sensor. This function is enabled and the polarity is set by bits MS[n] in the configuration register. The bias current generator generates dc current supplied from the AVDD supply.

## MODES OF OPERATION

This device has several operating modes whose primary purpose is power management. This section describes these modes.

### Continuous-Measurement Mode

During continuous-measurement mode, the device continuously makes measurements and places measured data in data output registers. Settings in the configuration register affect the data output rate (bits DO[n]), the measurement configuration (bits MS[n]), and the gain (bits GN[n]) when in continuous-measurement mode. To conserve current between measurements, the device is placed in a state similar to idle mode, but the mode is not changed to idle mode. That is, MD[n] bits are unchanged. Data can be re-read from the data output registers if necessary; however, if the master does not ensure that the data register is accessed before the completion of the next measurement, the new measurement may be lost. All registers maintain values while in continuous-measurement mode. The I<sup>2</sup>C bus is enabled for use by other devices on the network in while continuous-measurement mode.

### Single-Measurement Mode

This is the default single supply power-up mode. In dual supply configuration this is the default mode when AVDD goes high. During single-measurement mode, the device makes a single measurement and places the measured data in data output registers. Settings in the configuration register affect the measurement configuration (bits MS[n]), and the gain (bits GN[n]) when in single-measurement mode. After the measurement is complete and output data registers are updated, the device is placed sleep mode, and the mode register *is* changed to sleep mode by setting MD[n] bits. All registers maintain values while in single-measurement mode. The I<sup>2</sup>C bus is enabled for use by other devices on the network while in single-measurement mode.

### Idle Mode

During this mode the device is accessible through the I<sup>2</sup>C bus, but major sources of power consumption are disabled, such as, but not limited to, the ADC, the amplifier, the SVDD pin, and the sensor bias current. All registers maintain values while in idle mode. The I<sup>2</sup>C bus is enabled for use by other devices on the network while in idle mode.

### Sleep Mode

This is the default dual supply power-up mode when only DVDD goes high and AVDD remains low. During sleep mode the device functionality is limited to listening to the I<sup>2</sup>C bus. The internal clock is not running and register values are not maintained while in sleep mode. The only functionality that exists during this mode is the device is able to recognize and execute any instructions specific to this device but does not change from sleep mode due to other traffic on the I<sup>2</sup>C bus. The I<sup>2</sup>C bus is enabled for use by other devices on the network while in sleep mode. This mode has two practical differences from idle mode. First this state will create less noise on system since the clock is disabled, and secondly this state is a lower current consuming state since the clock is disabled.

### Off Mode

During off mode device is off. No device functionality exists. Both AVDD and DVDD are low. The I<sup>2</sup>C bus is enabled for use by other devices on the network in off mode. In this mode the I<sup>2</sup>C pins shall be in a high impedance state.

# HMC5843

## REGISTERS

This device is controlled and configured via a number of on-chip registers, which are described in this section. In the following descriptions, *set* implies a logic 1, and *reset* or *clear* implies a logic 0, unless stated otherwise.

### Register List

The table below lists the registers and their access. All address locations are 8 bits.

Address Location	Name	Access
00	Configuration Register A	Read/Write
01	Configuration Register B	Read/Write
02	Mode Register	Read/Write
03	Data Output X MSB Register	Read
04	Data Output X LSB Register	Read
05	Data Output Y MSB Register	Read
06	Data Output Y LSB Register	Read
07	Data Output Z MSB Register	Read
08	Data Output Z LSB Register	Read
09	Status Register	Read
10	Identification Register A	Read
11	Identification Register B	Read
12	Identification Register C	Read

Table 3: Register List

### Register Access

This section describes the process of reading from and writing to this device. The device uses an address pointer to indicate which register location is to be read from or written to. These pointer locations are sent from the master to this slave device and succeed the 7-bit address plus 1 bit read/write identifier.

To minimize the communication between the master and this device, the address pointer updates automatically without master intervention. This automatic address pointer update has two additional features. First when address 12 or higher is accessed the pointer updates to address 00 and secondly when address 09 is reached, the pointer rolls back to address 03. Logically, the address pointer operation functions as shown below.

```
If (address pointer = 09) then address pointer = 03
Else if (address pointer >= 12) then address pointer = 0
Else (address pointer) = (address pointer) + 1
```

The address pointer value itself cannot be read via the I<sup>2</sup>C bus.

Any attempt to read an invalid address location returns 0's, and any write to an invalid address location or an undefined bit within a valid address location is ignored by this device.

To move the address pointer to a random register location, first issue a "write" to that register location with no data byte following the command. For example, to move the address pointer to register 10, send 0x3C 0x0A.

# HMC5843

## Configuration Register A

The configuration register is used to configure the device for setting the data output rate and measurement configuration. CRA0 through CRA7 indicate bit locations, with CRA denoting the bits that are in the configuration register. CRA7 denotes the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

CRA7	CRA6	CRA5	CRA4	CRA3	CRA2	CRA1	CRA0
(0)	(0)	(0)	DO2 (1)	DO1 (0)	DO0 (0)	MS1 (0)	MS0 (0)

Table 4: Configuration Register A

Location	Name	Description
CRA7 to CRA5	0	These bits must be cleared for correct operation.
CRA4 to CRA2	DO2 to DO0	Data Output Rate Bits. These bits set the rate at which data is written to all three data output registers.
CRA1 to CRA0	MS1 to MS0	Measurement Configuration Bits. These bits define the measurement flow of the device, specifically whether or not to incorporate an applied bias to the sensor into the measurement.

Table 5: Configuration Register A Bit Designations

The Table below shows minimum output data rates given PVT conditions. All three channels shall be measured within a given data rate.

DO2	DO1	DO0	Minimum Data Output Rate (Hz)
0	0	0	0.5
0	0	1	1
0	1	0	2
0	1	1	5
1	0	0	10 (default)
1	0	1	20
1	1	0	50
1	1	1	Not used

Table 6: Data Output Rates

MS1	MS0	Mode
0	0	Normal measurement configuration (default). In normal measurement configuration the device follows normal measurement flow. The positive and negative pins of the resistive load are left floating and high impedance.
0	1	Positive bias configuration. In positive bias configuration, a positive current is forced across the resistive load.
1	0	Negative bias configuration. In negative bias configuration, a negative current is forced across the resistive load.
1	1	This configuration is not used.

Table 7: Measurement Modes

# HMC5843

## Configuration Register B

The configuration register B for setting the device gain. CRB0 through CRB7 indicate bit locations, with *CRB* denoting the bits that are in the configuration register. CRB7 denotes the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

CRB7	CRB6	CRB5	CRB4	CRB3	CRB2	CRB1	CRB0
GN2 (0)	GN1 (0)	GN0 (1)	(0)	(0)	(0)	(0)	(0)

Table 8: Configuration B Register

Location	Name	Description
CRB7 to CRB5	GN2 to GN0	Gain Configuration Bits. These bits configure the gain for the device. The gain configuration is common for all channels.
CRB4 to CRB0	0	This bit must be cleared for correct operation.

Table 9: Configuration Register B Bit Designations

The table below shows nominal gain settings.

GN2	GN1	GN0	Sensor Input Field Range:	Gain (counts/Gauss)	Output Range
0	0	0	$\pm 0.7\text{Ga}$	1620	0xF800–0x07FF (-2048–2047 )
0	0	1	$\pm 1.0\text{Ga}$	1300 (default)	0xF800–0x07FF (-2048–2047 )
0	1	0	$\pm 1.5\text{Ga}$	970	0xF800–0x07FF (-2048–2047 )
0	1	1	$\pm 2.0\text{Ga}$	780	0xF800–0x07FF (-2048–2047 )
1	0	0	$\pm 3.2\text{Ga}$	530	0xF800–0x07FF (-2048–2047 )
1	0	1	$\pm 3.8\text{Ga}$	460	0xF800–0x07FF (-2048–2047 )
1	1	0	$\pm 4.5\text{Ga}$	390	0xF800–0x07FF (-2048–2047 )
1	1	1	$\pm 6.5\text{Ga}$ (Not Recommended)	280	0xF800–0x07FF (-2048–2047 )

Table 10: Gain Settings

# HMC5843

The resolution of the HMC5843 is based on the gain selection (zero to 7) and the influence of the analog power supply rail (AVDD). The following graph shows the interaction.

## Mode Register

The mode register is an 8-bit register from which data can be read or to which data can be written. This register is used to select the operating mode of the device. MR0 through MR7 indicate bit locations, with *MR* denoting the bits that are in the mode register. MR7 denotes the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
(0)	(0)	(0)	(0)	(0)	(0)	MD1 (0)	MD0 (1)

Table 11: Mode Register

Location	Name	Description
MR7 to MR2	0	These bits must be cleared for correct operation.
MR1 to MR0	MD1 to MD0	Mode Select Bits. These bits select the operation mode of this device.

Table 12: Mode Register Bit Designations

MD1	MD0	Mode
0	0	Continuous-Conversion Mode. In continuous-conversion mode, the device continuously performs conversions and places the result in the data register. RDY goes high when new data is placed in all three registers. After a power-on or a write to the mode or configuration register, the first measurement set is available from all three data output registers after a period of $2/f_{DO}$ and subsequent measurements are available at a frequency of $f_{DO}$ , where $f_{DO}$ is the frequency of data output.
0	1	Single-Conversion Mode. When single-conversion mode is selected, device performs a single measurement, sets RDY high and returned to sleep mode. Mode register returns to sleep mode bit values. The measurement remains in the data output register and RDY remains high until the data output register is read or another conversion is performed.
1	0	Idle Mode. Device is placed in idle mode.
1	1	Sleep Mode. Device is placed in sleep mode.

Table 13: Operating Modes

### Data Output X Registers A and B

The data output X registers are two 8-bit registers, data output register A and data output register B. These registers store the measurement result from channel X. Data output X register A contains the MSB from the measurement result, and data output X register B contains the LSB from the measurement result. The value stored in these two registers is a 16-bit value in 2's complement form, whose range is 0xF800 to 0x07FF. DXRA0 through DXRA7 and DXRB0 through DXRB7 indicate bit locations, with *DXRA* and *DXRB* denoting the bits that are in the data output X registers. DXRA7 and DXRB7 denote the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

In the event the ADC reading overflows or underflows for the given channel, or if there is a math overflow during the bias measurement, this data register will contain the value -4096 in 2's complement form. This register value will clear when after the next valid measurement is made.

DXRA7	DXRA6	DXRA5	DXRA4	DXRA3	DXRA2	DXRA1	DXRA0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)
DXRB7	DXRB6	DXRB5	DXRB4	DXRB3	DXRB2	DXRB1	DXRB0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

Table 14: Data Output X Registers A and B

### Data Output Y Registers A and B

The data output Y registers are two 8-bit registers, data output register A and data output register B. These registers store the measurement result from channel Y. Data output Y register A contains the MSB from the measurement result, and data output Y register B contains the LSB from the measurement result. The value stored in these two registers is a 16-bit value in 2's complement form, whose range is 0xF800 to 0x07FF. DYRA0 through DYRA7 and DYRB0 through DYRB7 indicate bit locations, with *DYRA* and *DYRB* denoting the bits that are in the data output Y registers. DYRA7 and DYRB7 denote the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

In the event the ADC reading overflows or underflows for the given channel, or if there is a math overflow during the bias measurement, this data register will contain the value -4096 in 2's complement form. This register value will clear when after the next valid measurement is made.

DYRA7	DYRA6	DYRA5	DYRA4	DYRA3	DYRA2	DYRA1	DYRA0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)
DYRB7	DYRB6	DYRB5	DYRB4	DYRB3	DYRB2	DYRB1	DYRB0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

Table 15: Data Output Y Registers A and B

### Data Output Z Registers A and B

The data output Z registers are two 8-bit registers, data output register A and data output register B. These registers store the measurement result from channel Z. Data output Z register A contains the MSB from the measurement result, and data output Z register B contains the LSB from the measurement result. The value stored in these two registers is a 16-bit value in 2's complement form, whose range is 0xF800 to 0x07FF. DZRA0 through DZRA7 and DZRB0 through DZRB7 indicate bit locations, with *DZRA* and *DZRB* denoting the bits that are in the data output Z registers. DZRA7 and DZRB7 denote the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

In the event the ADC reading overflows or underflows for the given channel, or if there is a math overflow during the bias measurement, this data register will contain the value -4096 in 2's complement form. This register value will clear when after the next valid measurement is made.

DZRA7	DZRA6	DZRA5	DZRA4	DZRA3	DZRA2	DZRA1	DZRA0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)
DZRB7	DZRB6	DZRB5	DZRB4	DZRB3	DZRB2	DZRB1	DZRB0
(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

Table 16: Data Output Z Registers A and B

### Data Output Register Operation

When one or more of the output registers are read, new data cannot be placed in any of the output data registers until all six data output registers are read. This requirement also impacts DRDY and RDY, which cannot be cleared until new data is placed in all the output registers.

#### Status Register

The status register is an 8-bit read-only register. This register is used to indicate device status. SR0 through SR7 indicate bit locations, with *SR* denoting the bits that are in the status register. SR7 denotes the first bit of the data stream.

SR7	SR6	SR5	SR4	SR3	SR2	SR1	SR0
(0)	(0)	(0)	(0)	(0)	REN (0)	LOCK (0)	RDY(0)

Table 17: Status Register

Location	Name	Description
SR7 to SR3	0	These bits must be cleared for correct operation.
SR2	REN	Regulator Enabled Bit. This bit is set when the internal voltage regulator is enabled. This bit is cleared when the internal regulator is disabled.
SR1	LOCK	Data output register lock. This bit is set when this some but not all for of the six data output registers have been read. When this bit is set, the six data output registers are locked and any new data will not be placed in these register until on of four conditions are met: one, all six have been read or the mode changed, two, a POR is issued, three, the mode is changed, or four, the measurement is changed.
SR0	RDY	Ready Bit. Set when data is written to all six data registers. Cleared when device initiates a write to the data output registers, when in off mode, and after one or more of the data output registers are written to. When RDY bit is clear it shall remain cleared for a minimum of 5 $\mu$ s. DRDY pin can be used as an alternative to the status register for monitoring the device for conversion data.

Table 18: Status Register Bit Designations

### Identification Register A

The identification register A is used to identify the device. IRA0 through IRA7 indicate bit locations, with *IRA* denoting the bits that are in the identification register A. IRA7 denotes the first bit of the data stream. The number in parenthesis indicates the default value of that bit.

The identification value for this device is stored in this register. This is a read-only register.  
Register values. ASCII value *H*

IRA7	IRA6	IRA5	IRA4	IRA3	IRA2	IRA1	IRA0
0	1	0	0	1	0	0	0

Table 19: Identification Register A Default Values

### Identification Register B

The identification register B is used to identify the device. IRB0 through IRB7 indicate bit locations, with *IRB* denoting the bits that are in the identification register A. IRB7 denotes the first bit of the data stream.

Register values. ASCII value *4*

IRB7	IRB6	IRB5	IRB4	IRB3	IRB2	IRB1	IRB0
0	0	1	1	0	1	0	0

Table 20: Identification Register B Default Values

# HMC5843

## Identification Register C

The identification register C is used to identify the device. IRC0 through IRC7 indicate bit locations, with *IRC* denoting the bits that are in the identification register A. IRC7 denotes the first bit of the data stream.

Register values. ASCII value 3

IRC7	IRC6	IRC5	IRC4	IRC3	IRC2	IRC1	IRC0
0	0	1	1	0	0	1	1

Table 21: Identification Register C Default Values

## I<sup>2</sup>C COMMUNICATION PROTOCOL

The HMC5843 communicates via a two-wire I2C bus system as a slave device. The HMC5843 uses a simple protocol with the interface protocol defined by the I2C bus specification, and by this document. The data rate is at the standard-mode 100kbps or 400kbps rates as defined in the I2C Bus Specifications. The bus bit format is an 8-bit Data/Address send and a 1-bit acknowledge bit. The format of the data bytes (payload) shall be case sensitive ASCII characters or binary data to the HMC5843 slave, and binary data returned. Negative binary values will be in two's complement form. The default (factory) HMC5843 7-bit slave address is 0x3C for write operations, or 0x3D for read operations.

The HMC5843 Serial Clock (SCL) and Serial Data (SDA) lines have optional internal pull-up resistors, but require resistive pull-ups (Rp) between the master device (usually a host microprocessor) and the HMC5843. Pull-up resistance values of about 10k ohms are recommended with a nominal 1.8-volt digital supply voltage (DVDD). Other values may be used as defined in the I2C Bus Specifications or with the internal 50k ohm pull-up resistors (SDAP, SCLP) that can be tied to DVDD.

The SCL and SDA lines in this bus specification can be connected to a host of devices. The bus can be a single master to multiple slaves, or it can be a multiple master configuration. All data transfers are initiated by the master device which is responsible for generating the clock signal, and the data transfers are 8 bit long. All devices are addressed by I2C's unique 7 bit address. After each 8-bit transfer, the master device generates a 9<sup>th</sup> clock pulse, and releases the SDA line. The receiving device (addressed slave) will pull the SDA line low to acknowledge (ACK) the successful transfer or leave the SDA high to negative acknowledge (NACK).

Per the I2C spec, all transitions in the SDA line must occur when SCL is low. This requirement leads to two unique conditions on the bus associated with the SDA transitions when SCL is high. Master device pulling the SDA line low while the SCL line is high indicates the Start (S) condition, and the Stop (P) condition is when the SDA line is pulled high while the SCL line is high. The I2C protocol also allows for the Restart condition in which the master device issues a second start condition without issuing a stop.

All bus transactions begin with the master device issuing the start sequence followed by the slave address byte. The address byte contains the slave address; the upper 7 bits (bits7-1), and the Least Significant bit (LSb). The LSb of the address byte designates if the operation is a read (LSb=1) or a write (LSb=0). At the 9<sup>th</sup> clock pulse, the receiving slave device will issue the ACK (or NACK). Following these bus events, the master will send data bytes for a write operation, or the slave will clock out data with a read operation. All bus transactions are terminated with the master issuing a stop sequence.

I2C bus control can be implemented with either hardware logic or in software. Typical hardware designs will release the SDA and SCL lines as appropriate to allow the slave device to manipulate these lines. In a software implementation, care must be taken to perform these tasks in code.

## OPERATIONAL EXAMPLES

The HMC5843 has a fairly quick stabilization time from no voltage to stable and ready for data retrieval. The nominal 8.3 milli-seconds with the factory default single measurement mode means that the six Bytes of magnetic data registers (DXRA, DXRB, DYRA, DYRB, DZRA, and DZRB) are filled with a valid first measurement.

## HMC5843

To change the measurement mode to continuous measurement mode, after the 8.3 milli-second power-up time send the three bytes:

0x3C 0x02 0x00

This writes the 00 into the second register or mode register to switch from single to continuous measurement mode setting. With the data rate at the factory default of 10Hz updates, a 100 milli-second delay should be made by the I2C master before querying the HMC5843 data registers for new measurements. To clock out the new data, send:

0x3D, and clock out DXRA, DXRB, DYRA, DYRB, DZRA, DZRB located in registers 3 through 8. The HMC5843 will automatically re-point back to register 3 for the next 0x3D query, expected 100 milli-seconds or later. All six data registers must be read properly before new data can be placed in any of these data registers.

## SELF TEST OPERATION

To check the HMC5843 for proper operation, a self test feature is incorporated in which the sensor offset straps are excited to create a nominal field strength (bias field) to be measured. To implement this self test, the least significant bits (MS1 and MS0) of configuration register A are changed from 00 to 01.

Then, by placing the mode register into single-conversion mode (0x01), two data acquisition cycles will be made on each magnetic vector. The first acquisition will be a set pulse followed shortly by measurement data of the external field. The second acquisition will have the offset strap excited in the positive bias mode (~5.5mA in offset straps) to create about a 0.55 gauss self test field plus the external field. The first acquisition values will be subtracted from the second acquisition, and the net measurement will be placed into the data output registers.

If the configuration register B is left at the factory default value of 0x20, values around +715 ADC counts (0.55Ga \* 1300 counts/Ga) will be placed in the data output registers. To leave the self test mode, change MS1 and MS0 bit of the configuration register A back to 0x00. Also change the mode register if single-conversion mode is not the intended next mode of operation.

## SCALE FACTOR CALIBRATION

Using the method described above in section SELF TEST OPERATION, user can scale sensors' sensitivity to match each other. Since placing device in positive bias mode (or alternatively negative bias mode) applies the same artificial field on all three axes, the resulting ADC measurement in data output registers can be used to scale the sensors.

Alternatively, the built-in self test can be used to periodically compensate the scaling errors due to temperature variations. A compensation factor can be found by comparing the self test outputs with the ones obtained at a known temperature. For example, if the self test output is 715 at room temperature and 730 at the current temperature then a scale factor of (715/730) should be applied to all current magnetic readings. A temperature sensor is not required to use this method.

## EXTERNAL CAPACITORS

The two external capacitors should be ceramic type construction with low ESR characteristics. The exact ESR values are not critical but values less than 200 milli-ohms are recommended. Reservoir capacitor C1 is nominally 4.7  $\mu$ F in capacitance, with the set/reset capacitor C2 nominally 0.22  $\mu$ F in capacitance. Low ESR characteristics may not be in many small SMT ceramic capacitors (0402), so be prepared to up-size the capacitors to gain Low ESR characteristics.
