

# AS7620

## 650mA, Ultra low Ripple Step Down DC/DC Converter

### 1 General Description

The AS7620 is an easy-to-use, high-efficiency, high-voltage, hysteretic step-down DC-DC converter, operating in asynchronous mode. Its low-power architecture extends hold-up time in battery-backed and critical applications where maximum up-time over a wide input supply voltage range is needed, while still providing for high efficiencies of up to 90% during peak current demands.

Although the AS7620 is optimized for 24V applications found in industrial and medical systems, its ability to support 100% Duty Cycle makes the AS7620 ideal for applications demanding maximum up-time and soft power fail behavior. In combination with low idle current of only 30 $\mu$ A, on-demand switching reduces operating current at low load currents.

By selecting an appropriate inductor value, operating current can be lowered and switching frequencies tuned to certain load conditions.

A pin-strapped current limit input minimizes inductor peak current and thus inductor size and cost for any given application.

The device further includes output short-circuit protection and thermal shutdown. In shutdown mode, only 1 $\mu$ A (typ) of current is consumed.

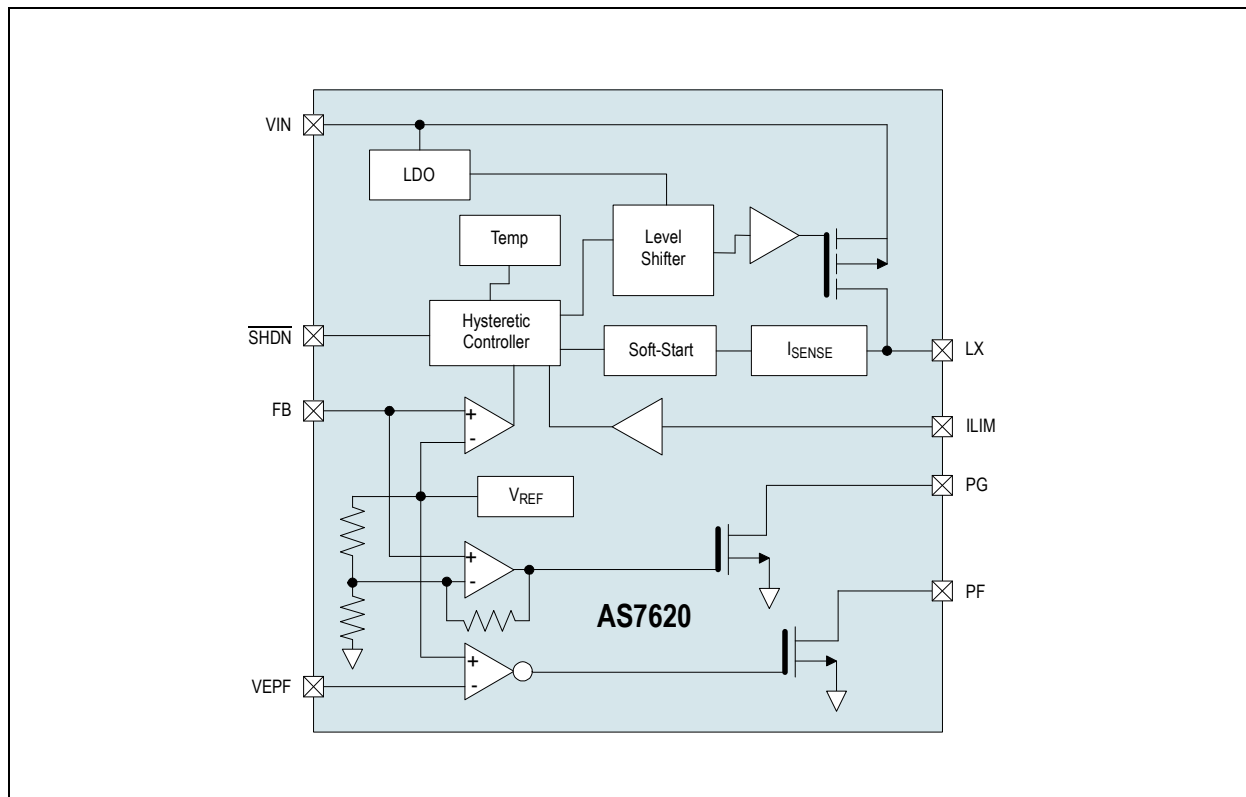

### 2 Key Features

- Low quiescent current for efficient partial load operation
- Wide Supply Voltage Range, 3.6V to 32V
- 100% Duty Cycle extends operating range
- Pin-programmable cycle-by-cycle current limit
- Integrated PMOS eliminates bootstrap capacitor
- Resistor-programmable Early Power Fail Warning Input
- Power-Good Flag
- Thermal Shutdown
- Fixed 3.3V and adjustable output (1.2V to  $V_{IN}$ )
- Small 4x4mm 12-Lead MLPQ Enhanced Power Package
- Specified from -40°C to +125°C junction and 85°C maximum ambient temperatures

### 3 Applications

The AS7620 is suitable for Industrial 24VDC applications like PLCs, robotics; Home Security and Building Control applications; Solid-state utility meters; Signage and LED column power; and Sensor interfaces.

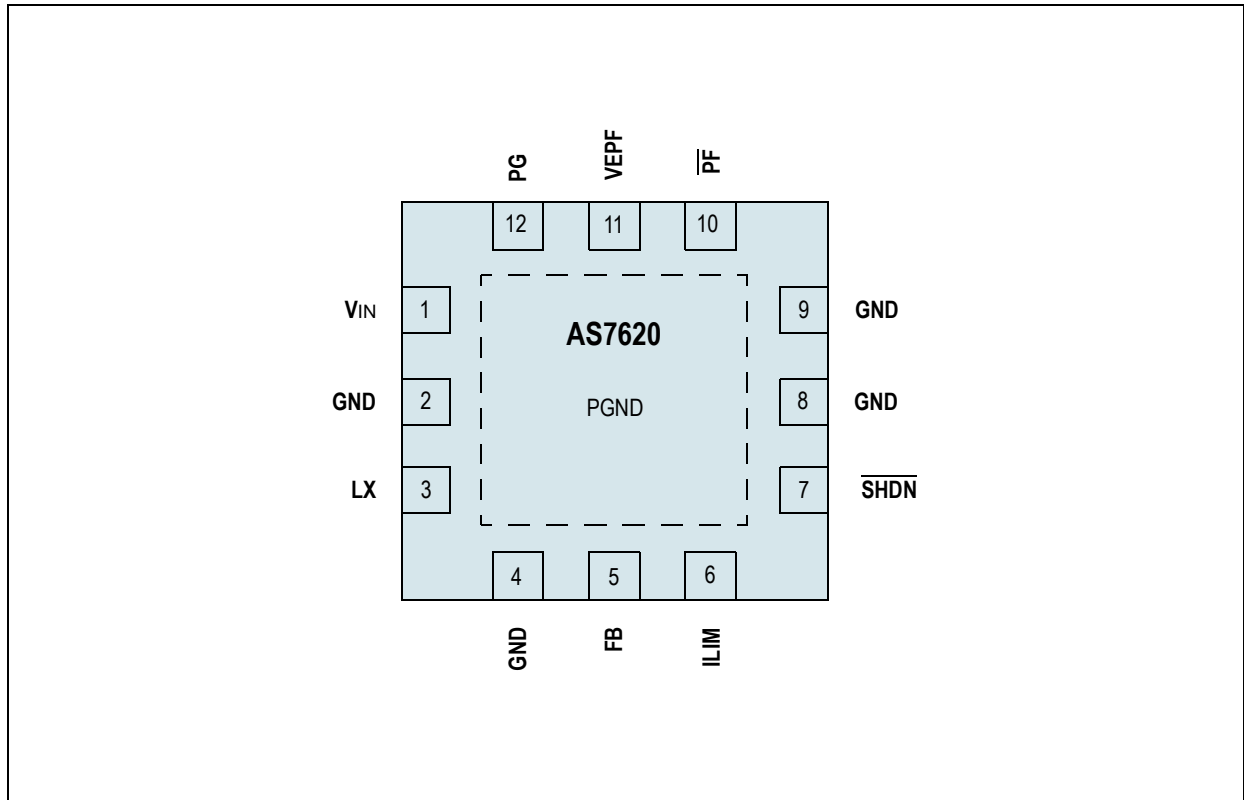

Figure 1. AS7620 - Block Diagram

## 4 Pin Assignments

Figure 2. Pin Assignments (Top View)

### 4.1 Pin Descriptions

Table 1. Pin Descriptions

Pin Number	Pin Name	Description
1	VIN	High Voltage Power Supply Input
2	GND	Must be connected to GND
3	LX	Power Output to Inductor
4	GND	Must be connected to GND
5	FB	Feedback input
6	ILIM	Current Limit input
7	$\overline{\text{SHDN}}$	Shutdown input, active low
8	GND	Must be connected to GND
9	GND	Must be connected to GND
10	$\overline{\text{PF}}$	Early Power Fail output, open drain, active LOW
11	VEPF	Comparator voltage input for early power fail warning
12	PG	Power Good, open drain, active HIGH output, monitors feedback voltage
Pad	PGND	Exposed pad. Connect to GND plane to help thermal dissipation

## 5 Absolute Maximum Ratings

Stresses beyond those listed in [Table 2](#) may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in [Electrical Characteristics on page 4](#) is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 2. Absolute Maximum Ratings

Parameter	Min	Max	Units	Comments
Electrical Parameters				
V <sub>IN</sub>	-0.3	40	V	
LX	-0.3	V <sub>IN</sub> +0.3	V	
FB, SHDN	-0.3	V <sub>IN</sub> +0.3 or 5.5	V	Whichever is lower
All other pins except LX, FB and SHDN	-0.3	3.6	V	
Input Current (latch-up immunity)	-30	+30	mA	Norm: JEDEC 78 <sup>1</sup>
Electrostatic Discharge				
Electrostatic Discharge HBM	+/- 1		kV	Norm: MIL 883 E method 3015
Temperature Ranges and Storage Conditions				
Package Power Dissipation		1	W	θJA = 32°C/W for a 4-layer board, 4 vias, T <sub>AMB</sub> = +70°C
Storage Temperature	-55	150	°C	
Junction Temperature		150	°C	
Package body temperature		260	°C	The reflow peak soldering temperature (body temperature) specified is in accordance with <i>IPC/JEDEC J-STD-020 "Moisture/Reflow Sensitivity Classification for Non-Hermetic Solid State Surface Mount Devices"</i> . The lead finish for Pb-free leaded packages is matte tin (100% Sn).
Humidity non-condensing	5	85	%	
Moisture Sensitive Level	3			Represents a max. floor life time of 168h

## 8.1 Shut Down

The device can be shut down by providing a voltage lower than 1V at the  $\overline{\text{SHDN}}$  pin (7). In this condition, the consumption is only 1 $\mu\text{A}$  (typ). The AS7620 is providing an internally regulated pull-up circuit. No external pull-up resistor shall be used, which could otherwise damage the shutdown input. Connect the  $\overline{\text{SHDN}}$  input directly to an open drain port only.

## 8.2 Soft Start

The device implements a soft start by limiting the inrush current into the output choke. Initially, the internal PMOS is turned on until the current reaches the programmed current limit (see [Current Limit on page 9](#)) and then is immediately turned off. It will be turned on again when the current approaches 0A. In this time frame, the FB voltage ( $V_{FB}$ ) will be lower than the reference and so the duty cycle will be driven by the current limit only.

### 8.3 Regulation

Both AS7620-A and AS7620-B are based on a hysteretic control method. Moreover, the switch current is monitored to make the converter always work in discontinuous current mode (DCM). The advantages of this type of control system can be summarized as following:

- High efficiency even at light load
- Intrinsically stable
- Simplicity
- Readiness during the load transient

The internal PMOS is switched on when the  $V_{FB}$  is lower than  $V_{REF}-V_{HYST}/2$  and the current is 0A (DCM). The on time will be terminated if the  $V_{FB}$  is over  $V_{REF}+V_{HYST}/2$  or if the current limit (CL) is triggered. In practice, considering the most common application conditions ( $L=10\mu H \div 100\mu H$ ;  $C=10\mu F \div 100\mu F$ ) and setting the CL threshold according to the load, the on time is normally terminated by the CL intervention and the output voltage ripple will stay within 1.25% of the output voltage (typ) or  $V_{HYST} * V_{OUT} / V_{REF}$ .

## 8.4 V<sub>OUT</sub> Selection

The AS7620-B features a 3.3V fixed output voltage. The AS7620-A provides an adjustable output from 1.2V (V<sub>REF</sub>) up to virtually V<sub>IN</sub> (see 100% Duty Cycle Operation on page 11). To select the desired V<sub>OUT</sub>, the related resistor divider has to be tuned according to the following formula:

$$V_{OUT} = V_{REF} \cdot \left(1 + \frac{R_h}{R_l}\right) \quad (EQ 1)$$

### Where:

R<sub>h</sub> is the high side resistor of the output divider

R<sub>l</sub> is the resistor of the output divider

**Note:** It is suggested to select resistors in the range of hundreds of kΩ in order to limit the current consumption.

## 8.5 Current Limit

The current is sensed during the on time of the internal PMOS. Three different current limit thresholds can be selected by the ILIM pin:

1. 240mA (typ) ILIM shorted to GND
2. 720mA (typ) ILIM shorted to V<sub>OUT</sub> (from 1.5V to 3.6V)
3. 1000mA (typ) ILIM floating

This threshold is intended as peak current limit. If the current reaches the threshold during the on time, the PMOS is turned off and it will be turned on again only when the current approaches 0A and the feedback voltage is equal or lower than V<sub>REF</sub>. The maximum output current is ILIM/2.

## 8.6 Switching Frequency

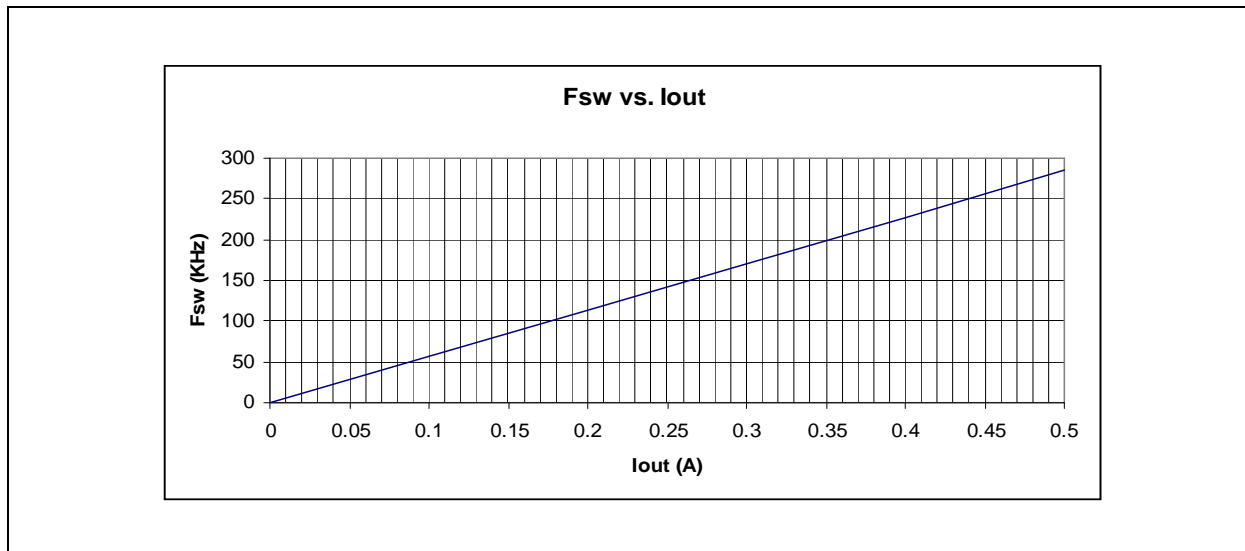

The switching frequency (f<sub>sw</sub>) changes according to the application conditions and, in particular, to the output current in order to optimize the efficiency in any load condition. Anyway, it is always possible to estimate the f<sub>sw</sub> during the design process. As described in the Regulation (refer to page 8) – the converter always works in DCM and, normally, the peak current into the inductor is the CL threshold (ILIM). The average of the inductor current must be equal to the output current. The following formula provides the relationship between inductor current and output current:

$$I_{OUT} = \frac{1}{T_{SW}} \cdot \frac{1}{2} \cdot \frac{ILIM^2 \cdot L \cdot V_{IN}}{(V_{IN} - V_{OUT}) \cdot V_{OUT}} \quad (EQ 2)$$

Consequently, the f<sub>sw</sub> can be expressed as following:

$$F_{SW} = \frac{2 \cdot I_{OUT} \cdot (V_{IN} - V_{OUT}) \cdot V_{OUT}}{ILIM^2 \cdot L \cdot V_{IN}} \quad (EQ 3)$$

Figure 18. Chart Illustrating the F<sub>sw</sub> vs. I<sub>OUT</sub> in a Standard Application (V<sub>IN</sub>=24V, V<sub>OUT</sub>=3.3V, L=10μH, ILIM=1A)

## 8.7 Power Fail / Power Good

AS7620A-B monitors input and output voltage by VEPF (pin 11) and VFB (pin 5) respectively. Two dedicated flags  $\overline{\text{PF}}$  (pin 10) and PG (pin 12) are provided outside to inform about early input power fail (active low) and output within regulation. Figure 19 illustrates the typical connection for VEPF. During start up, PF is initially low. By selecting R3, R4, R5 and R6, it is possible to set the desired input voltage threshold above which the input power is considered stable. Once  $V_{\text{IN}}$  (VDDH in Figure 19) reaches  $V_{\text{inH}}$ ,  $\overline{\text{PF}}$  is released and so an additional voltage contribution from VDD is added at the VPF pin, realizing in fact a hysteresis to eliminate  $\overline{\text{PF}}$  oscillation due to power supply noise.

Figure 19. Open-Drain Output Stage for Comparator

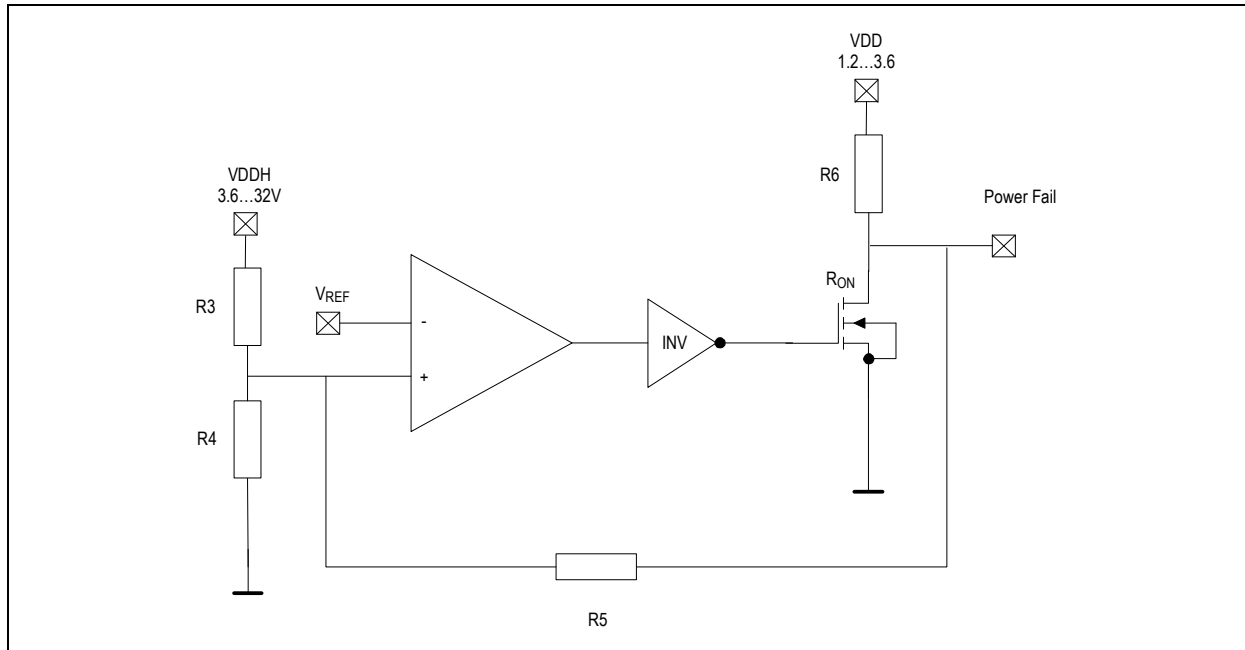

Table 5 provides the resistors values covering all the standard input BUS. The resistors values are 1% commercial values. It is mandatory to use the correct resistors values to guarantee the respect of maximum absolute voltages at EPF and PF pin. VDD has been considered 3.3V. Otherwise EPF pin should be shorted to GND and PF left floating.

Terminology:

VRST: Reset voltage for the EPF. It is 90% of the Input BUS voltage.

VTRIP: Trip voltage for the EPF. It is 80% of the Input BUS voltage.

Table 5. EPF Network Selection with Different Input BUS

$V_{\text{IN}}$ (V)	VRST (V)	VTRIP (V)	R3 (K $\Omega$ )	R4 (K $\Omega$ )	R5 (K $\Omega$ )	R6 (K $\Omega$ )
5	4.5	4	365	143	1740	1370
6	5.4	4.8	464	143	1870	1430
9	8.1	7.2	768	140	2050	1580
12	10.8	9.6	1070	140	2100	1650
15	13.5	12	1370	140	2150	1690
20	18	16	1870	140	2210	1740
24	21.6	19.2	2260	140	2260	1740
28	25.3	22.5	2670	140	2260	1740

## 8.8 Thermal Protection

The internal junction temperature is continuously monitored. If it reaches 150°C (min), the PMOS is turned off. The device can switch again if the temperature is decreased by at least 10°C. If the over-temperature persists, the device will be shut down again resulting in a hiccup mode for the output power.

## 9 Application Information

### 9.1 Input Capacitors

An input capacitor is required to sustain the peak current requested by the turning on of the internal PMOS. When used, the capacitor helps to reduce the noise and saves the input battery life. The input capacitor has to withstand the input RMS current, which can be calculated by the following formula:

$$I_{rms} = I_{OUT} \cdot \sqrt{\frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN}}} \quad (EQ 4)$$

While designing for wide input/output voltage range, the worst case of  $I_{rms} = 1/2 \cdot I_{OUT}$  must be considered. Suggested capacitors are low ESR OSCON, polymer, aluminum or MLCCs. Tantalum types are not recommended for their weakness in withstanding big inrush currents.

### 9.2 Output Inductor

The inductor together with the output capacitor represents the output filter. Using the AS7620, the inductor is charged and completely discharged at every switching cycle being that the converter is forced to work in DCM. Values from 10µH to 100µH are suitable to work with AS7620 and its selection should consider the following statements:

- Bigger inductor implies lower  $f_{sw}$
- Bigger inductor implies lower bandwidth

The inductor must be rated to withstand the peak current ( $ILIM$ ) and the RMS current  $I_{rms} = \sqrt{I_{OUT}^2 + \frac{\Delta L^2}{3}}$

### 9.3 Output Capacitor

The output capacitor together with the inductor represents the output filter. The bigger the capacitance is, the lower will be the output ripple. Usually, low ESR MLCCs are preferred as they are inexpensive and small in size. Any value from 10µF is suitable, considering the load transient specifications of the application as well.

### 9.4 Free Wheeling Diode

The inductor current is forced through the diode during the off-times. The average current flowing through it is  $\frac{1}{2} \cdot f_{sw} \cdot \frac{ILIM^2 \cdot L}{V_{OUT}}$

The reverse voltage must be higher than the input voltage and safely it is common to consider 30% more. Normally, a schottky diode is preferred because of its low forward voltage.

### 9.5 Stability

Even though the hysteretic voltage mode is intrinsically stable, an excessive noise at the FB could cause instability. For this reason care must be taken drawing the layout, reducing the noise and shielding the FB path from it. The main noise generator is the switching node, which is commutated from GND to  $V_{IN}$  by the internal PMOS and the free wheeling diode and through which a pulse current flows. It is wise to add a MLCC capacitor as close as possible to the  $V_{IN}$  pin of the device and provide a wide/short path between the LX pin and the external components (inductor and diode). It is preferable to draw the FB path as far as possible from the LX node and, perhaps, shielding it with a GND track. Another recommendation is to use low ESL output capacitors, thus avoiding electrolytic parts. A big ESL adds a square wave contribution on the FB that can make the device work improperly.

### 9.6 100% Duty Cycle Operation

Thanks to the PMOS structure of the internal switch, the device can actually work at 100% duty cycle. This feature is very helpful during the load transient, because the maximum power can be transferred to the output in order to recover as fastest. The device will try to work at 100% duty whenever the FB voltage is lower than the upper window's threshold. Moreover, in this condition, the safety is always guaranteed by the current limit.

## 9.7 Demo Board

A demonstration board is available to test the device functionalities and performance in a standard application. For further information, please refer to the AS7620EB datasheet.
