PAL20R8 Family

24-pin TTL Programmable Array Logic

DISTINCTIVE CHARACTERISTICS

- As fast as 7.5 ns maximum propagation delay
- Popular 24-pin architectures: 20L8, 20R8, 20R6, 20R4
- Programmable replacement for high-speed TTL logic
- Power-up reset for initialization
- Easy design with PALASM® software
- Programmable on standard PAL® device programmers
- 24-pin SKINNYDIP® and 28-pin PLCC packages save space

GENERAL DESCRIPTION

The PAL20R8 Family (PAL20L8, PAL20R8, PAL20R6, PAL20R4) is AMD's standard 24-pin PAL device family. The devices provide user-programmable logic for replacing conventional SSI/MSI gates and flip-flops at a reduced chip count.

The family allows the systems engineer to implement the design on-chip, by opening fuse links to configure AND and OR gates within the device, according to the desired logic function. Complex interconnections between gates, which previously required time-consuming layout, are lifted from the PC board and placed on silicon, where they can be easily modified during prototyping or production.

The PAL device implements the familiar Boolean logic transfer function, the sum of products. The PAL device is a programmable AND array driving a fixed OR array. The AND array is programmed to create custom product terms, while the OR array sums selected terms at the outputs.

In addition, the PAL device provides the following options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback

Product terms with all connections opened assume the logical HIGH state; product terms connected to both true and complement of any single input assume the logical LOW state. Registers consist of D-type flip-flops that are loaded on the LOW-to-HIGH transition of the clock. Unused input pins should be tied to V_{CC} or GND.

The entire PAL device family is supported by the PALASM software package. The PAL family is programmed on conventional PAL device programmers with appropriate personality and socket adapter modules. See the Programmer Reference Guide for approved programmers. Once the PAL device is programmed and verified an additional connection may be opened to prevent pattern readout. This feature secures proprietary circuits.

FUNCTIONAL DESCRIPTION

Standard 24-pin PAL Family

The standard 24-pin PAL family is comprised of four different devices, including both registered and combinatorial devices. All parts are produced with a fuse link at each input to the AND gate array, and connections may be selectively removed by applying appropriate voltages to the circuit. Utilizing an easily-implemented programming algorithm, these products can be rapidly programmed to any customized pattern. Information on approved programmers can be found in the Programmer Reference Guide. Extra test words are pre-programmed during manufacturing to ensure extremely high field programming yields, and provide extra test paths to achieve excellent parametric correlation.

Variable Input/Output Pin Ratio

The registered devices have twelve dedicated input lines, and each combinatorial output is an I/O pin. The PAL20L8 has fourteen dedicated input lines, and only six of the eight combinatorial outputs are I/O pins. Buffers for device inputs have complementary outputs to provide user-programmable input signal polarity. Unused input pins should be tied to V_{CC} or GND.

Programmable Three-State Outputs

Each output has a three-state output buffer with three-state control. On combinatorial outputs, a product term controls the buffer, allowing enable and disable to be a function of any product of device inputs or output feedback. The combinatorial output provides a bidirectional I/O pin, and may be configured as a dedicated input if the buffer is always disabled. On registered outputs, an input pin controls the enabling of the three-state outputs.

Registers with Feedback

Registered outputs are provided for data storage and synchronization. Registers are composed of D-type flip-flops that are loaded on the LOW-to-HIGH transition of the clock input.

Power-Up Reset

All flip-flops power-up to a logic LOW for predictable system initialization. Outputs of the PAL20R8 Family will be HIGH due to the active-low outputs. The V_{CC} rise

must be monotonic and the reset delay time is 1000 ns maximum.

Register Preload

T-46-19-13

Applies to -7 (-12 Mil), -10 (-15 Mil), Series Only

The register on the listed Series can be preloaded from the output pins to facilitate functional testing of complex state machine designs. This feature allows direct loading of arbitrary states, making it unnecessary to cycle through long test vector sequences to reach a desired state. In addition, transitions from illegal states can be verified by loading illegal states and observing proper recovery.

Security Fuse

After programming and verification, a PAL20R8 Family design can be secured by programming the security fuse. Once programmed, this fuse defeats readback of the internal programmed pattern by a device programmer, securing proprietary designs from competitors. When the security fuse is programmed, the array will read as if every fuse is unprogrammed. An exception is the -7 (-12 Mil) Series, where the array will read as if every fuse is programmed.

Pinouts

All members of the PAL20R8 Family have the same SKINNYDIP pinouts independent of technology, performance, and operating conditions. Because the 24-pin SKINNYDIP requires four no-connects when mapped into the 28-pin PLCC/LCC packages, the PLCC/LCC pinouts can vary.

Two different PLCC pinouts are offered. Newer devices and all future devices will follow the JEDEC electronics committee's standard pinout ("JEDEC pinout") with no-connects on pins 1, 8, 15, and 22. The devices following this pinout are the -7, -10, and B-2 Series. Older devices retain their original pinouts, with no-connects on pins 5, 8, 11, and 19. These include the B, A, and A-2 Series.

PAL20R8 Family devices with the MMI marking indicate the PLCC pinout by the package designator: FN indicates JEDEC, and NL indicates non-JEDEC. Devices with the AMD marking all follow the JEDEC pinout.

Two different LCC pinouts are offered for military products. Newer devices and all future devices will follow the JEDEC pinout with no-connects on pins 1, 8, 15, and 22. These include the -12 and -15 Series. Older devices retain their original pinouts, with no-connects on pins 4, 11, 18, and 25. These include the B, A, and A-2 Series.

Series	Com'l PLCC No-connects	Mil LCC No-connects
-7, -10, B-2	1, 8, 15, 22 (JEDEC)	N/A
-12, -15	N/A	1, 8, 15, 22 (JEDEC)
B, A, A-2	5, 8, 11, 19	4, 11, 18, 25

Quality and Testability

T-46-19-13

The PAL20R8 Family offers a very high level of built-in quality. Extra programmable fuses provide a means of verifying performance of all AC and DC parameters. In addition, this verifies complete programmability and functionality of the device to provide the highest programming yields and post-programming functional yields in the industry.

Technology

The high-speed -7 (-12 Mil) and -10 (-15 Mil) Series are fabricated with AMD's advanced oxide-isolated bipolar process. This process reduces parasitic capacitances and minimum geometries to provide higher performance. The array connections are formed with proven PtSi fuses for the -7 and TiW fuses for the -10. The B, B-2, A, and A-2 Series are fabricated with AMD's junction-isolated process, utilizing TiW fuses.

INPUT/OUTPUT EQUIVALENT SCHEMATICS

T-46-19-13

OUTPUT REGISTER PRELOAD

T-46-19-13

Applies to -7 (-12 Mil) Series Only

The preload function allows the register to be loaded from the output pins. This feature aids functional testing of sequential designs by allowing direct setting of output states. The procedure for preloading follows.

1. Raise V_{CC} to V_{CCH} .
2. Set $\overline{OE}$ to V_{IHP} to disable output registers.
3. Raise pin 2 to V_{HH} to enter preload mode.
4. Apply either V_{HH} or V_{ILP} to all registered outputs. Use V_{HH} to preload a LOW in the flip-flop; use V_{ILP} to

preload a HIGH in the flip-flop. Leave combinatorial outputs floating.

5. Lower pin 2 to V_{ILP} .
6. Remove V_{ILP}/V_{HH} from all registered output pins.
7. Lower $\overline{OE}$ to V_{ILP} to enable the output registers.
8. Verify V_{OL}/V_{OH} at all registered output pins. Note that because of the output inverter, a register that has been preloaded HIGH will provide a LOW at the output.

Parameter Symbol	Parameter Description	Min.	Rec.	Max.	Unit
V_{HH}	Super-level input voltage	10	11	12	V
V_{ILP}	Low-level input voltage	0	0	0.5	V

POWER-UP RESET

T-46-19-13

The power-up reset feature ensures that all flip-flops will be reset to LOW after the device has been powered up. The output state will be HIGH due to the inverting output buffer. This feature is valuable in simplifying state machine initialization. A timing diagram and parameter table are shown below. Due to the synchronous operation of the power-up reset and the wide range of ways V_{CC}

can rise to its steady state, two conditions are required to ensure a valid power-up reset. These conditions are:

1. The V_{CC} rise must be monotonic.
2. Following reset, the clock input must not be driven from LOW to HIGH until all applicable input and feedback setup times are met.
