Current Mode PWM Control Circuit with 50% Max Duty Cycle

The CS3844/45 provides all the necessary features to implement off-line fixed frequency current-mode control with a minimum number of external components.

The CS3844 family incorporates a new precision temperature-controlled oscillator to minimize variations in frequency. An internal toggle flip-flop, which blanks the output every other clock cycle, limits the duty-cycle range to less than 50%. An undervoltage lockout ensures that V_{REF} is stabilized before the output stage is enabled. In the CS2844/CS3844 turn on occurs at 16 V and turn off at 10 V. In the CS2845/CS3845 turn on is at 8.4 V and turn off at 7.6 V.

Other features include low start-up current, pulse-by-pulse current limiting, and a high-current totem pole output for driving capacitive loads, such as gate of a power MOSFET. The output is low in the off state, consistent with N-channel devices.

CIRCUIT DESCRIPTION

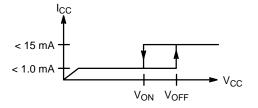

Figure 3. Startup Voltage for CSX844 and CSX845

Undervoltage Lockout

During Undervoltage Lockout (Figure 3), the output driver is biased to sink minor amounts of current. The output should be shunted to ground with a resistor to prevent activating the power switch with extraneous leakage currents.

PWM Waveform

To generate the PWM waveform, the control voltage from the error amplifier is compared to a current sense signal which represents the peak output inductor current (Figure 4). An increase in V_{CC} causes the inductor current slope to increase, thus reducing the duty cycle. This is an inherent feed–forward characteristic of current mode control, since the control voltage does not have to change during changes of input supply voltage.

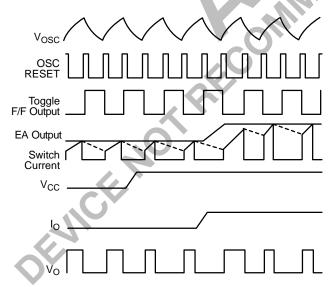

Figure 4. Timing Diagram

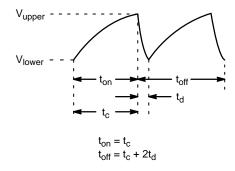

Figure 5. Duty Cycle Parameters

When the power supply sees a sudden large output current increase, the control voltage will increase allowing the duty cycle to momentarily increase. Since the duty cycle tends to exceed the maximum allowed to prevent transformer saturation in some power supplies, the internal oscillator waveform provides the maximum duty cycle clamp as programmed by the selection of OSC components.

Setting the Oscillator

The times t_c and t_d can be determined as follows:

$$t_{\text{C}} = R_{\text{T}} C_{\text{T}} \, \ln \! \left(\frac{\text{VREF} - \text{V}_{\text{lower}}}{\text{VREF} - \text{V}_{\text{upper}}} \right)$$

$$t_d = R_T C_T \ln \left(\frac{V_{REF} - I_d R_T - V_{lower}}{V_{REF} - I_d R_T - V_{lopper}} \right)$$

Substituting in typical values for the parameters in the above formulas:

 $V_{REF} = 5.0 \text{ V}, V_{upper} = 2.7 \text{ V}, V_{lower} = 1.0 \text{ V}, I_d = 8.3 \text{ mA}$ then:

$$t_C \approx 0.5534R_TC_T$$

$$t_{d} = R_{T}C_{T} \ ln \bigg(\frac{2.3 - 0.0083R_{T}}{4.0 - 0.0083R_{T}} \bigg)$$

For better accuracy R_T should be $\geq 10 \text{ k}\Omega$.

Grounding

High peak currents associated with capacitive loads necessitate careful grounding techniques. Timing and bypass capacitors should be connected close to Gnd in a single point ground.

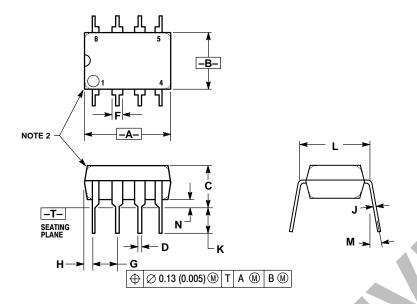

The transistor and 5.0 k Ω potentiometer are used to sample the oscillator waveform and apply an adjustable ramp to Sense.
