## World's Lowest Voltage Level Shifting GPIO with LED Driver and Keypad Engine

### GENERAL DESCRIPTION

The SX1508B and SX1509B are complete ultra low voltage General Purpose parallel Input/Output (GPIO) expanders ideal for low power handheld battery powered equipment. This family of GPIOs comes in 8-, 16-channel configuration and allows easy serial expansion of I/O through a standard 400kHz I<sup>2</sup>C interface. GPIO devices can provide additional control and monitoring when the microcontroller or chipset has insufficient I/O ports, or in systems where serial communication and control from a remote location is advantageous.

These devices can also act as a level shifter to connect a microcontroller running at one voltage level to a component running at a different voltage level, thus eliminating the need for extra level translating circuits. The core is operating as low as 1.425V while the dual I/O banks can operate between 1.2V and 3.6V independent of the core voltage and each other (5.5V tolerant).

The SX1508B and SX1509B feature a fully programmable LED Driver with internal oscillator for enhanced lighting control such as intensity (via 256-step PWM), blinking and breathing (fade in/out) make them highly versatile for a wide range of LED applications.

In addition, keypad applications are also supported with an on-chip scanning engine that enables continuous keypad monitoring up to 64 keys without any additional host interaction reducing bus activity.

The SX1508B and SX1509B have the ability to generate mask-programmable interrupts based on a falling/rising edge of any of its GPIO lines. A dedicated pin (NINT) indicates to a host controller that a state change occurred on one or more of the lines. Each GPIO is programmable via a bank of 8-bit configuration registers that include data, direction, pull-up/pull-down, interrupt mask and interrupt registers. These I/O expanders feature small footprint packages and are rated from -40°C to +85°C temperature range.

### KEY PRODUCT FEATURES

- 1.2V to 3.6V Low Operating Voltage with Dual Independent I/O Rails (VCC1, VCC2)
  - Enable Direct Level Shifting Between I/O Banks and Host Controller
- 5.5V Tolerant I/Os, Up to 15mA Output Sink on All I/Os (No Total Sink Current Limit)
- Integrated LED Driver for Enhanced Lighting
  - Intensity Control (256-step PWM)
  - Blink Control (224 On/Off values)
  - Breathing Control (224 Fade In/Out values)
- On-Chip Keypad Scanning Engine
  - Support Up to 8x8 Matrix (64 Keys)
  - Configurable Input Debouncer
- 8/16 Channels of True Bi-directional Style I/O
  - Programmable Pull-up/Pull-down
  - Push/Pull or Open-drain outputs
  - Programmable Polarity
- Open Drain Active Low Interrupt Output (NINT)
  - Bit Maskable
  - Programmable Edge Sensitivity
- Built-in Clock Management (Internal 2MHz Oscillator/External Clock Input, 7 clock values)
  - OSCIO can be Configured as GPO
- 400kHz I<sup>2</sup>C Compatible Slave Interface
- 4 User-Selectable I<sup>2</sup>C Slave Addresses
- Power-On Reset and Reset Input (NRESET)
- Ultra Low Current Consumption: 1uA Typ
- -40°C to +85°C Operating Temperature Range
- Up to 2kV HBM ESD Protection
- Small Footprint Packages
- Pb & Halogen Free, RoHS/WEEE compliant

### TYPICAL APPLICATIONS

- Cell phones, PDAs, MP3 players
- Digital camera, Notebooks, GPS Units
- Any battery powered equipment

(1) Assuming no load connected to outputs and inputs fixed to VCC1,2 or GND.

(2) Can be increased by tying together and driving simultaneously several I/Os.

(3) All values referred to  $V_{IHMR\ min}$  and  $V_{ILM\ max}$  levels.

(4) A device must internally provide a hold time of at least 300ns for the SDA signal (referred to  $V_{IHMR\ min}$ ) to bridge the undefined region of the falling edge of SCL.

(5) The maximum  $t_{HD:DAT}$  has only to be met if the device does not stretch the LOW period ( $t_{LOW}$ ) of the SCL signal.

(6) A Fast-mode I<sup>2</sup>C-bus device can be used in a Standard-mode I<sup>2</sup>C-bus system, but the requirement  $t_{SU:DAT} \geq 250$  ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal.

If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line  $t_r\ max + t_{SU:DAT} = 1000 + 250 = 1250$  ns (according to the Standard-mode I<sup>2</sup>C-bus specification) before the SCL line is released.

(7)  $C_b$  = total capacitance of one bus line in pF. If mixed with Hs-mode devices, faster fall-times are allowed.

(8) With RegHighInput bit enabled (VCCx min = 1.65V), else 3.6V (VCCx min = 1.2V)

### 4.3 Reset

#### 4.3.1 Hardware (NRESET)

The SX1508B and SX1509B generate their own power on reset signal after a power supply is connected to the VDDM pin. NRESET input pin can be used to reset the chip anytime, it must be connected to VDDM (or greater) either directly (if not used), or via a resistor.

Figure 6 – Power-On / Brown-out Reset Conditions

1. Device behavior is undefined until VDDM rises above VPOR, at which point internal reset procedure is started.
2. After  $t_{\text{RESET}}$ , the reset procedure is completed.
3. In operation, the SX1508B and SX1509B may be reset (POR like or LED driver counters only depending on RegMisc setting) at anytime by an external device driving NRESET low for  $t_{\text{PULSE}}$  or longer. Chip can be accessed normally again after NRESET rising edge.
4. During a brown-out event, if VDDM drops above VDROP a reset will not occur.
5. During a brown-out event, if VDDM drops between VDROP and VDROPL a reset may occur.
6. During a brown-out event, if VDDM drops below VDROPL a reset will occur next time VPOR is crossed.

Please note that a brown-out event is defined as a transient event on VDDM. If VDDM is attached to a battery, then the gradual decay of the battery voltage will not be interpreted as a brown-out event. Please also note that a sharp rise in VDDM ( $> 1\text{V}/\mu\text{s}$ ) may induce a circuit reset.

#### 4.3.2 Software (RegReset)

Writing consecutively 0x12 and 0x34 to RegReset register will reset all registers to their default values.

### 4.4 2-Wire Interface (I<sup>2</sup>C)

The SX1508B and SX1509B 2-wire interface operates only in slave mode. In this configuration, the device has one or 4 possible devices addresses defined by ADDR[1:0] pins:

Device	ADDR[1:0]	Address	Description
SX1508B	00	0x20 (0100000)	First address of the 2-wire interface
	01	0x21 (0100001)	Second address of the 2-wire interface
	10	0x22 (0100010)	Third address of the 2-wire interface
	11	0x23 (0100011)	Fourth address of the 2-wire interface
SX1509B	00	0x3E (0111110)	First address of the 2-wire interface
	01	0x3F (0111111)	Second address of the 2-wire interface
	10	0x70 (1110000)	Third address of the 2-wire interface
	11	0x71 (1110001)	Fourth address of the 2-wire interface

Table 6 - 2-Wire Interface Address

2 lines are used to exchange data between an external master host and the slave device:

- **SCL** : Serial **C**lock
- **SDA** : Serial **D**ata

## ADVANCED COMMUNICATIONS & SENSING

The SX1508B and SX1509B are read-write slave-mode I<sup>2</sup>C devices and comply with the Philips I<sup>2</sup>C standard Version 2.1 dated January, 2000. The SX1508B and SX1509B have a few user-accessible internal 8-bits registers to set the various parameters of operation (Cf. §5 for detailed configuration registers description). The I<sup>2</sup>C interface has been designed for program flexibility, in that once the slave address has been sent to the SX1508B or SX1509B enabling it to be a slave transmitter/receiver, any register can be written or read independently of each other. The start and stop commands frame the data-packet and the repeat start condition is allowed if necessary.

Seven bit addressing is used and ten bit addressing is not allowed. Any general call address will be ignored by the SX1508B and SX1509B. The SX1508B and SX1509B are not CBUS compatible and can operate in standard mode (100kbit/s) or fast mode (400kbit/s).

### 4.4.1 WRITE

After the start condition [S], the slave address (SA) is sent, followed by an eighth bit ('0') indicating a Write. The slave then Acknowledges [A] that it is being addressed, and the Master sends an 8 bit Data Byte consisting of the slave Register Address (RA). The Slave Acknowledges [A] and the master sends the appropriate 8 bit Data Byte (WD0). Again the slave Acknowledges [A]. In case the master needs to write more data, a succeeding 8 bit Data Byte will follow (WD1), acknowledged by the slave [A]. This sequence will be repeated until the master terminates the transfer with the Stop condition [P].

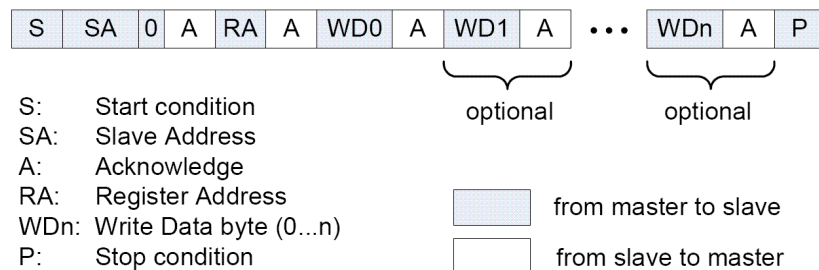

Figure 7 - 2-Wire Serial Interface, Write Operation

When successive register data (WD1...WDn) is supplied by the master, the register address can be automatically incremented or kept fixed depending on the setting programmed in RegMisc.

Figure 8 – Example: Write RegData Register

### 4.4.2 READ

After the start condition [S], the slave address (SA) is sent, followed by an eighth bit ('0') indicating a Write. The slave then Acknowledges [A] that it is being addressed, and the Master responds with an 8 bit Data consisting of the Register Address (RA). The slave Acknowledges [A] and the master sends the Repeated Start Condition [Sr]. Once again, the slave address (SA) is sent, followed by an eighth bit ('1') indicating a Read.

The slave responds with an Acknowledge [A] and the read Data byte (RD0). If the master needs to read more data it will acknowledge [A] and the slave will send the next read byte (RD1). This sequence can be repeated until the master terminates with a NACK [N] followed by a stop [P].

## ADVANCED COMMUNICATIONS & SENSING

Figure 9 - 2-Wire Serial Interface, Read Operation

When successive register data (RD1...RDn) is read by the master, the register address will be automatically incremented or kept fixed depending on the setting programmed in RegMisc.

### 4.5 I/O Banks

#### 4.5.1 Input Debouncer

Each input can be individually debounced by setting corresponding bits in RegDebounce register. At power up the debounce function is disabled. After enabling the debouncer, the change of the input value is accepted only if the input value is identical at two consecutive sampling times.

The debounce time common to all IOs can be set in RegDebounceConfig register from 0.5 to 64ms (fOSC = 2MHz).

#### 4.5.2 Keypad Scanning Engine

SX1508B, and SX1509B integrate a fully programmable keypad scanning engine to implement keypad applications up to 8x8 matrix (i.e. 64 keys).

Please note that SX1509B also implements an Auto Sleep/Wakeup feature to save power consumption when no key has been pressed for a programmed time.

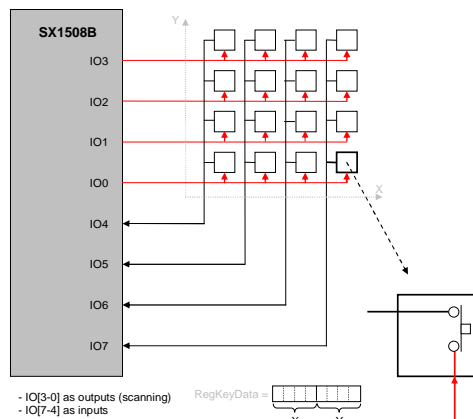

Figure 10 – 4x4 Keypad Connection to SX1508B

Following procedure should be implemented on the host controller for a 4x4 keypad:

1. Set RegDir to 0xF0 (IO[3:0] as outputs, IO[7:4] as inputs), set RegOpenDrain to 0x0F (IO[3:0] as open-drain outputs), set RegPullup to 0xF0 (pull-ups enabled on inputs IO[7:4]).
2. Enable and configure debouncing on IO[7:4] (RegDebounceEnable = 0xF0, Ex : RegDebounceConfig = 0x05)
3. Enable and configure keypad scanning engine (Ex : RegKeyConfig = 0x7D) This will start an infinite loop with the following sequence to IO[3:0]: ZZZ0, ZZ0Z, Z0ZZ, 0ZZZ. Make sure that scan interval is set to higher value than the debounce time.
4. When a key is pressed, NINT goes low, key scan is halted and the key coordinates are stored in RegKeyData:
  - The column data will be stored in RegKeyData[7:4] (Note: column indication is active low)

## ADVANCED COMMUNICATIONS & SENSING

- The row data will be stored in RegKeyData[3:0] (Note: row indication is active low)
- When RegKeyData is read, this data along with the interrupt is automatically cleared (same behavior as reading RegData) and the key scan continues to the next row.

5. Restart from point 4.

This implementation allows the host to handle both single and multi-touches easily (fast AAAAAA sequence is a long press of key A, fast ABABABAB sequence is key A and key B pressed together, etc)

### 4.5.3 Level Shifter

Because of their 5.5V tolerant I/O banks with independent supply voltages between 1.2V and 3.6V, the SX1508B and SX1509B can perform level shifting of signals from one I/O bank to another **without uC activity** by programming the corresponding configuration register bits accordingly in RegLevelShifter (and RegDir).

This can save significant BOM cost in a final application where only a few signals need to be level-shifted (no need for an additional external level shifter IC).

Figure 11 – Level Shifting Example

The minimum pulse width  $t_{LevelShiftMin}$  which can be level shifted properly depends on VCCx and VDDM:

$$t_{LevelShiftMin} = \text{Input Delay} + \text{Core Delay} + \text{Output Delay}$$

Input/Core/Output delays vs VCCx/VDDM are given in figures below.

## ADVANCED COMMUNICATIONS & SENSING

Figure 12 – Level Shifter Max Frequency Calculation Data

### 4.5.4 Polarity Inverter

Each IO's polarity can be individually inverted by setting corresponding bit in RegPolarity register. Please note that polarity inversion can also be combined with level shifting feature.

### 4.6 Interrupt (NINT)

At start-up, the transition detection logic is reset, and NINT is released to a high-impedance state. The interrupt mask register is set to 0xFF, disabling the interrupt output for transitions on all I/O ports. The transition flags are cleared to indicate no data changes.

An interrupt NINT can be generated on any programmed combination of I/Os rising and/or falling edges through the RegInterruptMask and RegSense registers.

If needed, the I/Os which triggered the interrupt can then be identified by reading RegInterruptSource register.

When NINT is low (i.e. interrupt occurred), it can be reset back high (i.e. cleared) by writing 0xFF in RegInterruptSource (this will also clear corresponding bits in RegEventStatus register).

The interrupt can also be cleared automatically when reading RegData register (Cf. RegMisc)

*Example: We want to detect rising edge of I/O[1] on SX1508B (NINT will go low).*

1. We enable interrupt on I/O[1] in RegInterruptMask

## ADVANCED COMMUNICATIONS & SENSING

⇒ *RegInterruptMask* = "XXXXXX0X"

2. We set edge sense for I/O[1] in *RegSense*

⇒ *RegSenseLow* = "XXXX01XX"

Please note that independently from the "user defined" process described above the keypad engine, when enabled, also uses NINT to indicate a key press.

Hence we have NINT = "user defined condition occurred" OR "keypad engine condition occurred".

### 4.7 Clock Management

A main oscillator clock *fOSC* is needed by the LED driver, keypad engine and debounce features.

Clock management block is illustrated in figure below.

Figure 13 – Clock Management Overview

The block is configured in register *RegClock* (Cf §5 for more detailed information):

- Selection of internal clock source: none (OFF) or internal oscillator or external clock input from OSCIN.
- Definition of OSCIO pin function (OSCIN or OSCOUT)
- OSCOUT frequency setting (sub-multiple of *fOSC*)

Please note that if needed the OSCOUT feature can be used as an additional GPO (Cf. *RegClock*)

### 4.8 LED Driver

#### 4.8.1 Overview

Every IO has its own independent LED driver (Cf §6.2 for typical LED connection), all IOs can perform intensity control (PWM) while some of them additionally include blinking and breathing features (Cf pin description §1)

The LED drivers of all I/Os share the same clock *ClkX* configurable in *RegMisc*[6:4]. Please note that for power consumption reasons *ClkX* is OFF by default.

Assuming *ClkX* is not OFF, LED driver for IO[X] is enabled when *RegLEDDriverEnable*[X] = 1 in which case it can operate in one of the three modes below:

- Static mode (all I/Os, with or without fade in/out)
- Single shot mode (blinking capable I/Os only, with or without fade in/out)
- Blink mode (blinking capable I/Os only, with or without fade in/out)

## ADVANCED COMMUNICATIONS & SENSING

Figure 14 – LED Driver Overview

Each IO[X] has its own set of programmable registers (Cf §5 for more detailed information):

- **RegTOnX** (blinking capable I/Os only): TOnX, ON time of IO[X]
- **RegIOOnX** (all I/Os): IOnX, ON intensity of IO[X]
- **RegOffX** (blinking capable I/Os only): TOffX and IOffX, OFF time and intensity of IO[X]
- **RegTRiseX** (breathing capable I/Os only): TRiseX, fade in time of IO[X]
- **RegTFallX** (breathing capable I/Os only): TFallX, fade out time of IO[X]

Please note that the LED driver mode is selectable for each IO bank between linear and logarithmic. (Cf §4.8.5)

All the figures assume normal IO polarity, for inverse polarity RegData control must be inverted (does not invert the polarity of the IO signal itself).

### 4.8.2 Static Mode

Only mode available for non blinking capable IOs (with Off intensity = 0), else invoked when TOnX = 0. If the I/O doesn't support fading the LED intensity will step directly to the IOnX/IOffX value.

Figure 15 – LED Driver Static Mode

### 4.8.3 Single Shot Mode

Invoked when TOnX != 0 and TOffX = 0.

If the I/O doesn't support fading the LED intensity will step directly to the IOnX/IOffX value.

### 4.8.4 Blink Mode

Invoked when TOnX != 0 and TOffX != 0.

If the I/O doesn't support fading the LED intensity will step directly to the IOnX/IOffX value.

### 4.8.5 LED Driver Modes

For each IO bank, the LED driver mode of fading capable IOs can be selected between linear or logarithmic in RegMisc.

#### 4.8.6 Synchronization of LED Drivers across several ICs

When several GPIO expanders are used in the same application it may be useful that their LEDs drivers are synchronous for coherent global operation.

In this case all ICs should share their fOSC through their OSCIO pins and have their reset connected together.

When RegMisc of each IC is set accordingly, NRESET signal can then be used to reset all devices' internal counters (but not the register settings) and allow synchronous LED operation (blinking, fading) across multiple devices.

#### 4.8.7 Tutorial

Below are the steps required to use the LED driver with the typical LED connection described §6.2:

- Disable input buffer (RegInputDisable)
- Disable pull-up (RegPullUp)

## ADVANCED COMMUNICATIONS & SENSING

- Enable open drain (RegOpenDrain)
- Set direction to output (RegDir) – by default RegData is set high => LED OFF
- Enable oscillator (RegClock)
- Configure LED driver clock and mode if relevant (RegMisc)
- Enable LED driver operation (RegLEDDriverEnable)
- Configure LED driver parameters (RegTOn, RegIOn, RegOff, RegTRise, RegTFall)
- Set RegData bit low => LED driver started

### 6 APPLICATION INFORMATION

#### 6.1 Typical Application Circuit

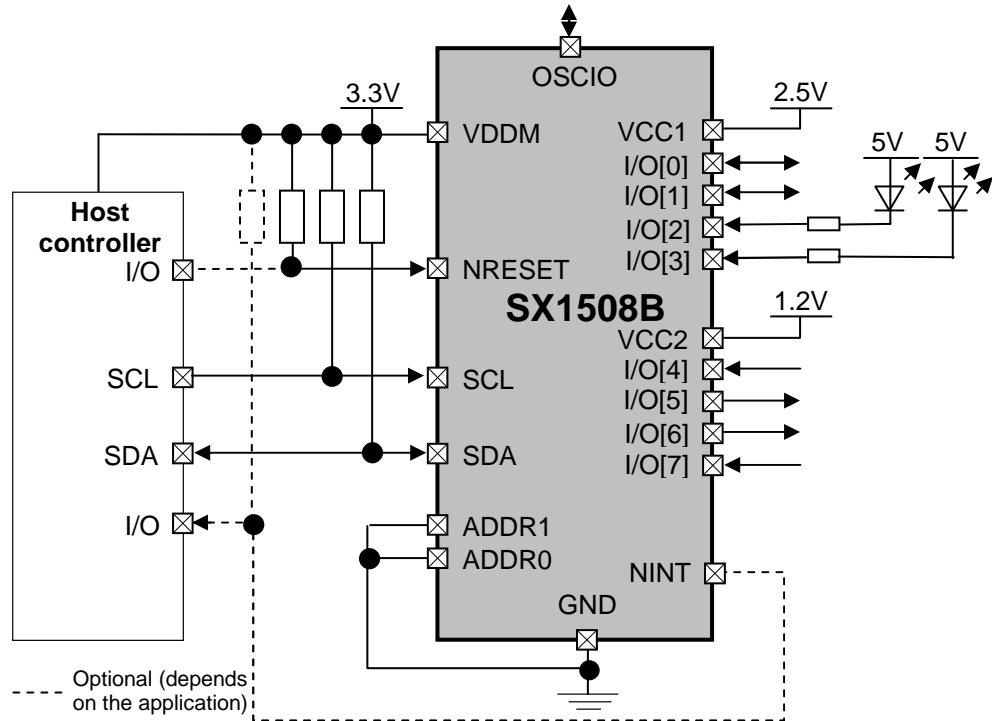

Figure 19 - Typical Application Schematic

#### 6.2 Typical LED Connection

Typical LED Connection is described below. The LED is usually connected to a high voltage (VBAT) to take advantage of the high sink current of the I/O and to accommodate high LED threshold voltages (VLED).

Please note that in this configuration the IO must be programmed as open drain output (RegOpenDrain) with no pull-up (RegPullUp) and input buffer must be disabled (RegInputBufferDisable).

VCCx can take any value without compromising LED operation.

\*LED colour/technology dependent

Figure 20 – Typical LED Operation

Serial R must be calculated for IOL not to exceed its max spec (Cf. Table 5) else VOL will increase.

### 7 PACKAGING INFORMATION

#### 7.1 QFN-UT 20-pin Outline Drawing

QFN-UT 20-pin, 3 x 3 mm, 0.4 mm pitch

NOTES:

1. CONTROLLING DIMENSIONS ARE IN MILLIMETERS (ANGLES IN DEGREES).
2. COPLANARITY APPLIES TO THE EXPOSED PAD AS WELL AS THE TERMINALS.
3. DAP IS 1.90 x 1.90mm.

#### 7.2 QFN-UT 20-pin Land Pattern

NOTES:

1. CONTROLLING DIMENSIONS ARE IN MILLIMETERS (ANGLES IN DEGREES).
2. THIS LAND PATTERN IS FOR REFERENCE PURPOSES ONLY. CONSULT YOUR MANUFACTURING GROUP TO ENSURE YOUR COMPANY'S MANUFACTURING GUIDELINES ARE MET.
3. THERMAL VIAS IN THE LAND PATTERN OF THE EXPOSED PAD SHALL BE CONNECTED TO A SYSTEM GROUND PLANE. FAILURE TO DO SO MAY COMPROMISE THE THERMAL AND/OR FUNCTIONAL PERFORMANCE OF THE DEVICE.
