DS1232LP

Low-Power MicroMonitor Chip

Description

The DS1232LP/LPS Low-Power MicroMonitor Chip monitors three vital conditions for a microprocessor: power supply, software execution, and external override. First, a precision temperature-compensated reference and comparator circuit monitors the status of V_{CC} . When an out-of-tolerance condition occurs, an internal power-fail signal is generated, which forces reset to the active state. When V_{CC} returns to an in-tolerance condition, the reset signals are kept in the active state for a minimum of 250ms to allow the power supply and processor to stabilize.

Key Features

- Super-low power version of DS1232
- 50 μ A quiescent current
- Halts and restarts an out-of-control microprocessor
- Automatically restarts microprocessor after power failure
- Monitors pushbutton for external override
- Accurate 5% or 10% microprocessor power supply monitoring
- 8-pin DIP, 8-pin SO, or space saving μ SOP package available
- Optional 16-pin SO package available
- Industrial temperature -40°C to +85°C available, designated N

PBRST	- Pushbutton Reset Input
TD	- Time Delay Set
TOL	- Selects 5% or 10% V_{CC} Detect
GND	- Ground
RST	- Reset Output (Active High)
\overline{RST}	- Reset Output (Active Low, open drain)
\overline{ST}	- Strobe Input
V_{CC}	- +5 Volt Power

DESCRIPTION

The DS1232LP/LPS Low Power MicroMonitor Chip monitors three vital conditions for a microprocessor: power supply, software execution, and external over-ride. First, a precision temperature-compensated reference and comparator circuit monitors the status of V_{CC} . When an out-of-tolerance condition occurs, an internal power-fail signal is generated which forces reset to the active state. When V_{CC} returns to an in-tolerance condition, the reset signals are kept in the active state for a minimum of 250 ms to allow the power supply and processor to stabilize.

The second function the DS1232LP/LPS performs is pushbutton reset control. The DS1232LP/LPS debounces the pushbutton input and guarantees an active reset pulse width of 250 ms minimum. The third function is a watchdog timer. The DS1232LP/LPS has an internal timer that forces the reset signals to the active state if the strobe input is not driven low prior to timeout. The watchdog timer function can be set to operate on timeout settings of approximately 150 ms, 600 ms, and 1.2 seconds.

OPERATION - POWER MONITOR

The DS1232LP/LPS detects out-of-tolerance power supply conditions and warns a processor-based system of impending power failure. When V_{CC} falls below a preset level as defined by TOL, the V_{CC} comparator outputs the signals RST and \overline{RST} . When TOL is connected to ground, the RST and \overline{RST} signals become active as V_{CC} falls below 4.75 volts. When TOL is connected to V_{CC} , the RST and \overline{RST} signals become active as V_{CC} falls below 4.5 volts. The RST and \overline{RST} are excellent control signals for a microprocessor, as processing is stopped at the last possible moments of valid V_{CC} . On power-up, RST and \overline{RST} are kept active for a minimum of 250 ms to allow the power supply and processor to stabilize.

OPERATION - PUSHBUTTON RESET

The DS1232LP/LPS provides an input pin for direct connection to a pushbutton (Figure 1). The pushbutton reset input requires an active low signal. Internally, this input is debounced and timed such that RST and \overline{RST} signals of at least 250 ms minimum are generated. The 250 ms delay starts as the pushbutton reset input is released from low level.

OPERATION - WATCHDOG TIMER

The watchdog timer function forces RST and \overline{RST} signals to the active state when the \overline{ST} input is not stimulated for a predetermined time period. The time period is set by the TD input to be typically 150 ms with TD connected to ground, 600 ms with TD left unconnected, and 1.2 seconds with TD connected to V_{CC} . The watchdog timer starts timing out from the set time period as soon as RST and \overline{RST} are inactive. If a high-to-low transition occurs on the \overline{ST} input pin prior to timeout, the watchdog timer is reset and begins to timeout again. If the watchdog timer is allowed to timeout, then the RST and \overline{RST} signals are driven to the active state for 250 ms minimum. The \overline{ST} input can be derived from microprocessor address signals, data signals, and/or control signals. When the microprocessor is functioning normally, these signals would, as a matter of routine, cause the watchdog to be reset prior to timeout. To guarantee that the watchdog timer does not timeout, a high-to-low transition must occur at or less than the minimum shown in Table 1. A typical circuit example is shown in Figure 2.

ABSOLUTE MAXIMUM RATINGS*

Voltage on V_{CC} Pin Relative to Ground	-0.5V to +7.0V
Voltage on I/O Relative to Ground	-0.5V to $V_{CC} + 0.5V$

NOTES:

1. All voltages referenced to ground.
2. Measured with outputs open and \overline{ST} and \overline{PBRST} within 0.5V of supply rails.
3. \overline{PBRST} is internally pulled up to V_{CC} with an internal impedance of 40k typical.
4. $t_R = 5 \mu s$.
5. \overline{RST} is an open-drain output.
6. Must not exceed t_{TD} minimum. See Table 1.
7. RST remains within 0.5V of V_{CC} on power-down until V_{CC} drops below 2.0V. \overline{RST} remains within 0.5V of GND on power-down until V_{CC} drops below 2.0V.
8. Measured with outputs open and \overline{ST} and \overline{PBRST} at TTL levels.
9. Watchdog can not be disabled. It must be strobed to avoid resets.
