

4-Mbit serial SPI bus EEPROM

SO8N (MN)
150 mil width

TSSOP8 (DW)
169 mil width

WLCSP8 (2.809 × 1.863 mm)

Product status link

[M95M04-DR](#)

Product label

Features

SPI interface

- Compatible with the serial peripheral interface (SPI) bus

Memory

- 4-Mbit (512-Kbyte) of EEPROM
- Page size: 512-byte
- Additional 512-byte lockable identification page

Supply voltage

- 1.8 V to 5.5 V

Temperature

- Operating temperature range: -40 °C up to +85 °C

Clock frequency

- Up to 5 MHz for $V_{CC} \geq 1.8$ V
- Up to 10 MHz for $V_{CC} \geq 2.5$ V

Fast write cycle time

- Byte and page write within 5 ms (typically 3.8 ms)

Performance

- More than 4 million write cycles
- More than 200-year data retention
- ESD human body model 4000 V

Ultra-low power current consumption

- 600 nA (typical) in standby mode
- 650 μ A (typical) for read current
- 600 μ A (typical) for write current

Advanced feature

- Schmitt trigger inputs for noise filtering
- Software write protection by quarter block
- Hardware write protection
- Enhanced ESD/latch-up protection

Packages (ECOPACK2-compliant)

- SO8N
- TSSOP8
- WLCSP8

1 Description

The M95M04-DR device is electrically erasable programmable memory (EEPROM) organized as 524288 x 8 bits, accessed through the SPI bus.

The M95M04-DR can operate with a supply range from 1.8 to 5.5 V, and is guaranteed over the -40 °C/+85 °C temperature range.

The M95M04-DR offer an additional page, named the identification page (512 bytes). The identification page can be used to store sensitive application parameters that can be (later) permanently locked in read-only mode.

Figure 1. Logic diagram

DT45413V2

The SPI bus signals are C, D and Q, as shown in Figure 1 and Table 1. The device is selected when Chip select ($\overline{S}$) is driven low. Communications with the device can be interrupted when the $\overline{HOLD}$ is driven low.

Table 1. Signal names

Signal name	Function	Direction
C	Serial clock	Input
D	Serial data input	Input
Q	Serial data output	Output
$\overline{S}$	Chip select	Input
$\overline{W}$	Write protect	Input
$\overline{HOLD}$	Hold	Input
V _{CC}	Supply voltage	-
V _{SS}	Ground	-

Figure 2. 8-pin package connections (top view)

DT51579V2

1. See [Section 10: Package information](#) for package dimensions, and how to identify pin 1.

Figure 3. WLCSP connections

DT38243V2

Table 2. Signals vs. bump position

Position	A	B	C	D
1	-	-	C	-
2	V_{CC}	$\overline{HOLD}$	-	D
3	$\overline{S}$	-	-	V_{SS}
4	-	Q	$\overline{W}$	-

2 Memory organization

The memory is organized as shown in the following figure.

Figure 4. Block diagram

* Identification page

3 Signal description

During all operations, V_{CC} must be held stable and within the specified valid range: $V_{CC(min)}$ to $V_{CC(max)}$. All of the input and output signals must be held high or low (according to voltages of V_{IH} , V_{OH} , V_{IL} or V_{OL} , as specified in [Section 9: DC and AC parameters](#)). These signals are described next.

3.1 Serial data output (Q)

This output signal is used to transfer data serially out of the device. Data are shifted out on the falling edge of the serial clock (C).

3.2 Serial data input (D)

This input signal is used to transfer data serially into the device. It receives instructions, addresses, and data to be written. Values are latched on the rising edge of the serial clock (C).

3.3 Serial clock (C)

This input signal provides the timing for the serial interface. Instructions, addresses, or data present at serial data input (D) are latched on the rising edge of the serial clock (C). Data on serial data output (Q) changes on its falling edge.

3.4 Chip select ($\overline{S}$)

When this input signal is high, the device is deselected and the serial data output (Q) is at high impedance. The device is in the standby power mode, unless an internal write cycle is in progress. Driving chip select ($\overline{S}$) low selects the device, placing it in the active power mode.

After power-up, a falling edge is required before the start of any instruction.

3.5 Hold ($\overline{HOLD}$)

The hold ($\overline{HOLD}$) signal is used to pause any serial communications with the device without deselecting it.

During the hold condition, the serial data output (Q) is high impedance, while the states of the serial data input (D) and serial clock (C) are don't care.

To start the hold condition, the device must be selected, with chip select ($\overline{S}$) driven low.

3.6 Write protect ($\overline{W}$)

The main purpose of this input signal is to freeze the size of the area of memory protected against write instructions, as specified by the values of the BP1 and BP0 bits in the status register.

This pin must be driven either high or low and must remain stable during all write instructions.

3.7 V_{CC} supply voltage

V_{CC} is the supply voltage.

3.8 V_{SS} ground

V_{SS} is the reference for all signals, including V_{CC} .

4 Connecting to the SPI bus

All instructions, addresses and input data bytes are shifted in to the device, most significant bit first. The serial data input (D) is sampled on the first rising edge of the serial clock (C) after chip select ($\overline{S}$) goes low.

All output data bytes are shifted out of the device, most significant bit first. The serial data output (Q) is latched on the first falling edge of the serial clock (C) after the instruction (such as the read from memory array and read status register instructions) have been clocked into the device.

Figure 5. Bus controller and memory devices on the SPI bus

DT19755V6

1. The write protect ($\overline{W}$) and hold ($\overline{HOLD}$) signals should be driven, high or low as appropriate.

Figure 5 shows an example of three memory devices connected to an SPI bus controller. Only one device is selected at a given time, so only one of them drives the serial data output (Q) line at that time. The other devices are in a high impedance state. The pull-up resistor R (represented in Figure 5) ensures that a device is not selected if the bus controller leaves the $\overline{S}$ line in the high-Z state.

In applications where the bus controller leaves all SPI bus lines in high impedance at the same time (for example, if the bus controller is reset during the transmission of an instruction), it is recommended to connect the clock line (C) to an external pull-down resistor. This ensures that, if all inputs/outputs become high impedance, the C line is pulled low (while the $\overline{S}$ line is pulled high). This prevents $\overline{S}$ and C from becoming high at the same time, ensuring that the t_{SCH} requirement is met. The typical value of R is 100 k Ω .

4.1 SPI modes

The device can be driven by a microcontroller with its SPI peripheral running in one of the following two modes:

- CPOL = 0, CPHA = 0
- CPOL = 1, CPHA = 1

For these two modes, the input data is latched on the rising edge of the serial clock (C), and the output data is available from the falling edge of the serial clock (C).

The difference between the two modes, as shown in Figure 6, is the clock polarity when the bus controller is in standby mode and not transferring data:

- C remains at 0 for (CPOL = 0, CPHA = 0)
- C remains at 1 for (CPOL = 1, CPHA = 1)

Figure 6. SPI modes supported

DT42674V2

5 Operating features

5.1 Supply voltage (V_{CC})

5.1.1 Operating supply voltage (V_{CC})

Prior to selecting the memory and issuing instructions to it, a valid and stable V_{CC} voltage within the specified [$V_{CC}(\min)$, $V_{CC}(\max)$] range must be applied (see operating conditions in [Section 9: DC and AC parameters](#)). This voltage must remain stable and valid until the end of the transmission of the instruction and, for a Write instruction, until the completion of the internal write cycle (t_W). In order to secure a stable DC supply voltage, it is recommended to decouple the V_{CC} line with a suitable capacitor (usually in the range between 10 and 100 nF) close to the V_{CC} / V_{SS} device pins.

5.1.2 Device reset

In order to prevent erroneous instruction decoding and inadvertent write operations during power-up, a power-on-reset (POR) circuit is included. At power-up, the device does not respond to any instruction until V_{CC} reaches the POR threshold voltage. This threshold is lower than the minimum V_{CC} operating voltage (see operating conditions in [Section 9: DC and AC parameters](#)).

At power-up, when V_{CC} passes over the POR threshold, the device is reset and is in the following state:

- in Standby power mode,
- deselected,
- Status register values:
 - the write enable latch (WEL) bit is reset to 0
 - the write in progress (WIP) bit is reset to 0
 - the SRWD, BP1 and BP0 bits remain unchanged (non-volatile bits).

It is important to note that the device must not be accessed until V_{CC} reaches a valid and stable level within the specified [$V_{CC}(\min)$, $V_{CC}(\max)$] range, as defined under Operating conditions in [Section 9: DC and AC parameters](#).

5.1.3 Power-up conditions

When the power supply is turned on, V_{CC} rises continuously from V_{SS} to V_{CC} . During this time, the chip select ($\bar{S}$) line is not allowed to float but should follow the V_{CC} voltage. It is therefore recommended to connect the $\bar{S}$ line to V_{CC} via a suitable pull-up resistor (see [Figure 5](#)).

In addition, the chip select ($\bar{S}$) input offers a built-in safety feature, as the $\bar{S}$ input is edge-sensitive as well as level-sensitive: after power-up, the device does not become selected until a falling edge has first been detected on chip select ($\bar{S}$). This ensures that chip select ($\bar{S}$) must have been high, prior to going low to start the first operation.

The V_{CC} voltage has to rise continuously from 0 V up to the minimum V_{CC} operating voltage defined in [Section 9: DC and AC parameters](#).

5.1.4 Power-down

During power-down (continuous decrease of the V_{CC} supply voltage below the minimum V_{CC} operating voltage defined in [Section 9: DC and AC parameters](#)), the device must be:

- deselected (chip select $\overline{S}$ must be allowed to follow the voltage applied on V_{CC})
- in standby power mode (there must not be any internal write cycle in progress).

5.2 Active power and standby power modes

When chip select ($\overline{S}$) is low, the device is selected, and in the active power mode. The device consumes I_{CC} .

When chip select ($\overline{S}$) is high, the device is deselected. If a write cycle is not currently in progress, the device then goes into the standby power mode, and the device consumption drops to I_{CC1} , as specified in DC characteristics (see [Section 9: DC and AC parameters](#)).

5.3 Hold condition

The hold ($\overline{HOLD}$) signal is used to pause any serial communications with the device without resetting the clocking sequence.

To enter the hold condition, the device must be selected with the chip select ($\overline{S}$) low. During this condition, the serial data output (Q) is in high impedance, while the serial data input (D) and the serial clock (C) are don't care.

Typically, the device remains selected for the entire duration of the hold condition. Deselecting the device while it is in the hold condition resets the state of the device. This mechanism can be used, if required, to reset the ongoing processes. It resets the internal logic, except the WEL and WIP bits of the status register.

Note: When the device receives a write command (instruction + address + 8-bit data bytes), deselecting it triggers the write cycle of this decoded command.

Figure 7. Hold condition activation

The hold condition starts when the hold ($\overline{HOLD}$) signal is driven low while the serial clock (C) is already low (as shown in [Figure 7](#)).

[Figure 7](#) also shows what happens if the rising and falling edges do not align with the serial clock (C) being low.

5.4 Status register

The status register contains several status and control bits that can be read or set by specific instructions. See [Section 6.3: Read status register \(RDSR\)](#) for a detailed description of the status register bits.

5.5 Data protection and protocol control

The device features the following data protection mechanisms:

- Before accepting the execution of the write and write status register instructions, the device checks whether the number of clock pulses comprised in the instructions is a multiple of eight.
- All instructions that modify data must be preceded by a write enable (WREN) instruction to set the write enable latch (WEL) bit.
- The block protect (BP1, BP0) bits in the status register are used to configure part of the memory as read-only.
- The write protect ($\overline{W}$) signal is used to protect the block protect (BP1, BP0) bits in the status register.

For any instruction to be accepted, and executed, chip select ($\overline{S}$) must be driven high after the rising edge of serial clock (C) for the last bit of the instruction, and before the next rising edge of serial clock (C).

Two points to note in the previous sentence:

- The “last bit of the instruction” can be the eighth bit of the instruction code, or the eighth bit of a data byte, depending on the instruction (except for read status register (RDSR) and read (READ) instructions).
- The “next rising edge of serial clock (C)” might (or might not) be the next bus transaction for some other device on the SPI bus.

Table 3. Write-protected block size

Status register bits		Protected block	Protected array addresses
BP1	BP0		
0	0	None	None
0	1	Upper quarter	60000h - 7FFFFh
1	0	Upper half	40000h - 7FFFFh
1	1	Whole memory	00000h - 7FFFFh

6 Instructions

Each command is composed of bytes (MSB bit transmitted first), initiated with the instruction byte, as summarized in [Table 4](#).

If an invalid instruction is sent (one not contained in [Table 4](#)), the device automatically enters in a wait state until deselected.

Table 4. Instruction set

Instruction	Description	Instruction format
WREN	Write enable	0000 0110
WRDI	Write disable	0000 0100
RDSR	Read status register	0000 0101
WRSR	Write status register	0000 0001
READ	Read from memory array	0000 0011
WRITE	Write to memory array	0000 0010
RDID	Read identification page	1000 0011
WRID	Write identification page	1000 0010
RDLS	Read identification page lock status	1000 0011
LID	Lock identification page in react-only mode	1000 0010

For read and write commands to memory array and identification page the address is defined by three bytes as explained in [Table 5](#).

Table 5. Significant bits within the address bytes

Instruction ⁽¹⁾⁽²⁾	Upper address byte								Middle address byte								Lower address byte							
	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
READ or WRITE	X	X	X	X	X	A18	A17	A16	A15	A14	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0
RDID or WRID	X	X	X	X	X	X	X	X	X	X	X	X	X	0	X	A8	A7	A6	A5	A4	A3	A2	A1	A0
RDLS or LID	X	X	X	X	X	X	X	X	X	X	X	X	X	1	X	X	X	X	X	X	X	X	X	X

1. A: Significant address bit

2. X: Don't Care bit

6.1 Write enable (WREN)

The write enable latch (WEL) bit must be set prior to each WRITE and WRSR instruction. The only way to do this is to send a write enable instruction to the device.

As shown in Figure 8, to send this instruction to the device, chip select ($\overline{S}$) is driven low, and the bits of the instruction byte are shifted in, on serial data input (D). The device then enters a wait state. It waits for the device to be deselected by chip select ($\overline{S}$) being driven high.

Figure 8. Write enable (WREN) sequence

DT1137V1

6.2 Write disable (WRDI)

One way of resetting the write enable latch (WEL) bit is to send a write disable instruction to the device.

As shown in Figure 9, to send this instruction to the device, chip select ($\overline{S}$) is driven low, and the bits of the instruction byte are shifted in, on serial data input (D).

The device then enters a wait state. It waits for the device to be deselected, by chip select ($\overline{S}$) being driven high. The write enable latch (WEL) bit, in fact, becomes reset by any of the following events:

- Power-up
- WRDI instruction execution
- WRSR instruction completion
- WRITE instruction completion.

Figure 9. Write disable (WRDI) sequence

DT71378V1

6.3 Read status register (RDSR)

The read status register (RDSR) instruction is used to read the status register. The status register may be read at any time, even while a write or write status register cycle is in progress. When one of these cycles is in progress, it is recommended to check the write in progress (WIP) bit before sending a new instruction to the device. It is also possible to read the Status register continuously, as shown in Figure 10

Figure 10. Read Status register (RDSR) sequence

The status and control bits of the status register are detailed in the following subsections.

6.3.1 WIP bit

The WIP bit (write in progress) is a read-only flag that indicates the ready/busy state of the device. When a write command (WRITE, WRSR, WRID, LID) has been decoded and a write cycle (t_W) is in progress, the device is busy and the WIP bit is set to 1. When WIP = 0 the device is ready to decode a new command.

During a write cycle, reading continuously the WIP bit allows to detect when the device becomes ready (WIP = 0) to decode a new command.

6.3.2 WEL bit

The WEL bit (write enable latch) bit is a flag that indicates the status of the internal write enable latch. When WEL is set to 1, the write instructions (WRITE, WRSR, WRID, LID) are executed; when WEL is set to 0, any decoded write instruction is not executed.

The WEL bit is set to 1 with the WREN instruction. The WEL bit is reset to 0 after the following events:

- Write disable (WRDI) instruction completion
- Write instructions (WRITE, WRSR, WRID, LID) completion including the write cycle time t_W
- Power-up

6.3.3 BP1, BP0 bits

The block protect (BP1, BP0) bits are non volatile. They define the size of the area to be software-protected against Write instructions. These bits are written with the write status register (WRSR) instruction. When one or both of the block protect (BP1, BP0) bits is set to 1, the relevant memory area (as defined in Table 3) becomes protected against write (WRITE) instructions. The block protect (BP1, BP0) bits can be written provided that the hardware protected mode has not been set.

6.3.4 SRWD bit

The status register write disable (SRWD) bit is operated in conjunction with the write protect ($\overline{W}$) signal. The status register write disable (SRWD) bit and write protect ($\overline{W}$) signal enable the device to be put in the hardware protected mode (when the status register write disable (SRWD) bit is set to 1, and write protect ($\overline{W}$) is driven low). In this mode, the non-volatile bits of the status register (SRWD, BP1, BP0) become read-only bits and the write status register (WRSR) instruction is no longer accepted for execution.

Table 6. Status register format

6.4 Write status register (WRSR)

The write status register (WRSR) instruction is used to write new values to the status register. Before it can be accepted, a write enable (WREN) instruction must have been previously executed.

The write Status register (WRSR) instruction is entered by driving chip select ($\overline{S}$) low, followed by the instruction code, the data byte on serial data input (D) and chip select ($\overline{S}$) driven high. Chip select ($\overline{S}$) must be driven high after the rising edge of serial clock (C) that latches in the eighth bit of the data byte, and before the next rising edge of serial clock (C). Otherwise, the write status register (WRSR) instruction is not executed.

The instruction sequence is shown in Figure 11.

Figure 11. Write status register (WRSR) sequence

Driving the chip select ($\overline{S}$) signal high at a byte boundary of the input data triggers the self-timed write cycle that takes t_W to complete (as specified in AC tables in [Section 9: DC and AC parameters](#)).

While the write status register cycle is in progress, the status register may still be read to check the value of the write in progress (WIP) bit: the WIP bit is 1 during the self-timed write cycle t_W , and 0 when the write cycle is complete. The WEL bit (Write enable latch) is also reset at the end of the write cycle t_W .

The write status register (WRSR) instruction enables the user to change the values of the BP1, BP0 and SRWD bits:

- The block protect (BP1, BP0) bits define the size of the area that is to be treated as read-only, as defined in [Table 3](#).
- The SRWD (status register write disable) bit, in accordance with the signal read on the write protect pin (W), enables the user to set or reset the write protection mode of the status register itself, as defined in [Table 7](#). When in write-protected mode, the write status register (WRSR) instruction is not executed.

The contents of the SRWD and BP1, BP0 bits are updated after the completion of the WRSR instruction, including the t_W write cycle.

The write status register (WRSR) instruction has no effect on the b6, b5, b4, b1, b0 bits in the status register. Bits b6, b5, b4 are always read as 0.

Table 7. Protection modes

W signal	SRWD bit	Mode	Write protection of the Status register	Memory content	
				Protected area ⁽¹⁾	Unprotected area ⁽¹⁾
1	0	Software-protected (SPM)	Status register is writable (if the WREN instruction has set the WEL bit).	Write-protected	Ready to accept write instructions
0	0		The values in the BP1 and BP0 bits can be changed.		
1	1				
0	1	Hardware-protected (HPM)	Status register is hardware write-protected. The values in the BP1 and BP0 bits cannot be changed.	Write-protected	Ready to accept write instructions

1. As defined by the values in the Block protect (BP1, BP0) bits of the Status register. See [Table 3](#).

The protection features of the device are summarized in [Table 7](#).

When the status register write disable (SRWD) bit in the status register is 0 (its initial delivery state), it is possible to write to the status register (provided that the WEL bit has previously been set by a WREN instruction), regardless of the logic level applied on the write protect ($\overline{W}$) input pin.

When the status register write disable (SRWD) bit in the Status register is set to 1, two cases should be considered, depending on the state of the write protect ($\overline{W}$) input pin:

- If write protect ($\overline{W}$) is driven high, it is possible to write to the status register (provided that the WEL bit has previously been set by a WREN instruction).
- If write protect ($\overline{W}$) is driven low, it is not possible to write to the status register even if the WEL bit has previously been set by a WREN instruction. (attempts to write to the status register are rejected, and are not accepted for execution). As a consequence, all the data bytes in the memory area, which are software-protected (SPM) by the block protect (BP1, BP0) bits in the status register, are also hardware-protected against data modification.

Regardless of the order of the two events, the hardware-protected mode (HPM) can be entered by:

- either setting the SRWD bit after driving the write protect ($\overline{W}$) input pin low,
- or driving the write protect ($\overline{W}$) input pin low after setting the SRWD bit.

Once the hardware-protected mode (HPM) has been entered, the only way of exiting it is to pull high the write protect ($\overline{W}$) input pin.

If the write protect ($\overline{W}$) input pin is permanently tied high, the hardware-protected mode (HPM) can never be activated, and only the software-protected mode (SPM), using the block protect (BP1, BP0) bits in the status register, can be used.

6.5 Read from memory array (READ)

As shown in Figure 12, to send this instruction to the device, chip select ($\overline{S}$) is first driven low. The bits of the instruction byte and address bytes are then shifted in, on serial data input (D). The address is loaded into an internal address register, and the byte of data at that address is shifted out, on serial data output (Q).

Figure 12. Read from memory array (READ) sequence

If chip select ($\overline{S}$) continues to be driven low, the internal address register is incremented automatically, and the byte of data at the new address is shifted out.

When the highest address is reached, the address counter rolls over to zero, allowing the read cycle to be continued indefinitely. The whole memory can, therefore, be read with a single READ instruction.

The read cycle is terminated by driving chip select ($\overline{S}$) high. The rising edge of the chip select ($\overline{S}$) signal can occur at any time during the cycle.

The instruction is not accepted, and is not executed, if a write cycle is currently in progress.

DT13878aV3

6.6 Write to memory array (WRITE)

As shown in Figure 13, to send this instruction to the device, chip select ($\bar{S}$) is first driven low. The bits of the instruction byte, address byte, and at least one data byte are then shifted in, on serial data input (D).

The instruction is terminated by driving chip select ($\bar{S}$) high at a byte boundary of the input data. The self-timed write cycle, triggered by the chip select ($\bar{S}$) rising edge, continues for a period t_W (as specified in AC characteristics in Section 9: DC and AC parameters), at the end of which the write in progress (WIP) bit is reset to 0.

Figure 13. Byte write (WRITE) sequence

DT30905V3

In the case of Figure 13, chip select ($\bar{S}$) is driven high after the eighth bit of the data byte has been latched in, indicating that the instruction is being used to write a single byte. However, if chip select ($\bar{S}$) continues to be driven low (as shown in Figure 14), the next byte of input data is shifted in, so that more than a single byte, starting from the given address towards the end of the same page, can be written in a single internal write cycle.

Each time a new data byte is shifted in, the least significant bits of the internal address counter are incremented. If more bytes are sent than fits up to the end of the page, a condition known as “roll-over” occurs. In case of roll-over, the bytes exceeding the page size are overwritten from location 0 of the same page.

The instruction is not accepted, and is not executed, under the following conditions:

- if the write enable latch (WEL) bit has not been set to 1 (by executing a write enable instruction just before),
- if a write cycle is already in progress,
- if the device has not been deselected, by driving high chip select ($\bar{S}$), at a byte boundary (after the eighth bit, b0, of the last data byte that has been latched in),
- if the addressed page is in the region protected by the block protect (BP1 and BP0) bits.

Note:

The self-timed write cycle t_W is internally executed as a sequence of two consecutive events: [Erase addressed byte(s)], followed by [Program addressed byte(s)]. An erased bit is read as “0” and a programmed bit is read as “1”.

Figure 14. Page write (WRITE) sequence

DT30906V3

6.7 Read identification page

The identification page (512 bytes) is an additional page that can be written and (later) permanently locked in Read-only mode.

This page is read with the read identification page instruction (see Table 4). The chip select signal ($\bar{S}$) is first driven low, the bits of the instruction byte and address bytes are then shifted in, on serial data input (D). Address bit A10 must be 0, upper address bits are "Don't care", and the data byte pointed to by the lower address bits [A8:A0] is shifted out on serial data output (Q). If chip select ($\bar{S}$) continues to be low, the internal address register is automatically incremented, and the byte of data at the new address is shifted out.

The number of bytes to read in the ID page must not exceed the page boundary, otherwise unexpected data are read (e.g. when reading the ID page from location 200d, the number of bytes must be lower than or equal to 312d, as the ID page boundary is 512 bytes).

The read cycle is terminated by driving chip select ($\bar{S}$) high. The rising edge of the chip select ($\bar{S}$) signal can occur at any time during the cycle. The first byte addressed can be any byte within any page.

The instruction is not accepted, and is not executed, if a write cycle is currently in progress.

Figure 15. Read identification page sequence

DT30907V2

6.8 Write identification page

The identification page (512 bytes) is an additional page that can be written and (later) permanently locked in Read-only mode.

Writing this page is achieved with the write identification page instruction (see [Table 4](#)). The chip select signal ($\overline{S}$) is first driven low. The bits of the instruction byte, address bytes, and at least one data byte are then shifted in on serial data input (D). Address bit A10 must be 0, upper address bits are "Don't care", the lower address bits [A8:A0] define the byte address within the identification page. The instruction sequence is shown in [Figure 16](#).

Figure 16. Write identification page sequence

6.9 Read lock status

The read lock status instruction (see Table 4) is used to check whether the identification page is locked or not in Read-only mode. The read lock status sequence is defined with the chip select ($\overline{S}$) first driven low. The bits of the instruction byte and address bytes are then shifted in on serial data input (D). Address bit A10 must be 1, all other address bits are "Don't Care". The lock bit is the LSB (least significant bit) of the byte read on serial data output (Q). It is at "1" when the lock is active and at "0" when the lock is not active. If chip select ($\overline{S}$) continues to be driven low, the same data byte is shifted out. The read cycle is terminated by driving chip select ($\overline{S}$) high.

The instruction sequence is shown in Figure 17.

Figure 17. Read lock status sequence

DT30910V2

6.10 Lock ID

The lock ID instruction permanently locks the identification page in read-only mode. Before this instruction can be accepted, a write enable (WREN) instruction must have been executed.

The lock ID instruction is issued by driving chip select ($\overline{S}$) low, sending the instruction code, the address and a data byte on serial data input (D), and driving chip select ($\overline{S}$) high. In the address sent, A10 must be equal to 1, all other address bits are "Don't Care". The data byte sent must have the b0 bit equal to 1 (b0=1) and the others value of the bits b7 to b1 are "Don't Care". The data byte has the following format: xxxx xxx1 (where x = Don't Care)".

Chip select ($\overline{S}$) must be driven high after the rising edge of serial clock (C) that latches in the eighth bit of the data byte, and before the next rising edge of serial clock (C). Otherwise, the lock ID instruction is not executed.

Driving chip select ($\overline{S}$) high at a byte boundary of the input data triggers the self-timed write cycle whose duration is t_W (as specified in AC characteristics in [Section 9: DC and AC parameters](#)). The instruction sequence is shown in [Figure 18](#).

The instruction is discarded, and is not executed, under the following conditions:

- If a write cycle is already in progress
- If block protect bits (BP1,BP0) = (1,1)
- If a rising edge on chip select ($\overline{S}$) happens outside of a byte boundary
- If the identification is already locked.

Figure 18. Lock ID sequence

DT30911V3

6.11 Error correction code (ECC x 4) and write cycling

M95M04-DR devices offer an error correction code (ECC), an internal logic function transparent for the SPI communication protocol.

The ECC logic is implemented on each group of four EEPROM bytes (A group of four bytes is located at addresses $[4*N, 4*N+1, 4*N+2, 4*N+3]$, where N is an integer). Even if the ECC function is performed on groups of four bytes, a single byte can be written/cycled independently. In this case, the ECC function also writes/cycles the three other bytes located in the same group. As a consequence, the maximum cycling budget is defined at group level and the cycling can be distributed over the four bytes of the group: the sum of the cycles seen by byte0, byte1, byte2 and byte3 of the same group must remain below the maximum value defined in [Section 9](#).

7 Power-up and delivery state

7.1 Power-up state

After power-up, the device is in the following state:

- Standby power mode
- Deselected (after power-up, a falling edge is required on chip select ($\overline{S}$) before any instructions can be started)
- Not in the hold condition
- Write enable latch (WEL) is reset to 0
- Write in progress (WIP) is reset to 0

The SRWD, BP1 and BP0 bits of the status register are unchanged from the previous power-down (they are nonvolatile bits).

7.2 Initial delivery state

The device is delivered with the memory array and identification page bits set to all 1s (each byte = FFh). The status register write disable (SRWD) and block protect (BP1 and BP0) bits are initialized to 0.

8 Maximum ratings

Stressing the device outside the ratings listed in Table 8 may cause permanent damage to the device. These are stress ratings only, and operation of the device at these, or any other conditions outside those indicated in the operating sections of this specification, is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 8. Absolute maximum ratings

Symbol	Parameter	Min.	Max.	Unit
T _{AMB}	Ambient operating temperature	-40	130	°C
T _{STG}	Storage temperature	-65	150	
T _{LEAD}	Lead temperature during soldering	See note ⁽¹⁾		
V _O	Output voltage	-0.50	V _{CC} + 0.6	V
V _I	Input voltage	-0.50	6.5	
V _{CC}	Supply voltage	-0.50	6.5	
I _{OL}	DC output current (Q = 0)	-	5	mA
I _{OH}	DC output current (Q = 1)	-	5	
V _{ESD}	Electrostatic discharge voltage (human body model) ⁽²⁾	-	4000	V

1. Compliant with JEDEC standard J-STD-020 (for small-body, Sn-Pb or Pb free assembly), the ST ECOPACK 7191395 specification, and the European directive on Restrictions on Hazardous Substances (RoHS directive 2011/65/EU of July 2011).
2. Positive and negative pulses applied on different combinations of pin connections, according to AEC-Q100-002 (compliant with ANSI/ESDA/JEDEC JS-001, C1 = 100 pF, R1 = 1500 Ω, R2 = 500 Ω).

9 DC and AC parameters

This section summarizes the operating conditions and the DC/AC characteristics.

Table 9. Operating conditions (range R)

Symbol	Parameter	Min.	Max.	Unit
V_{CC}	Supply voltage	1.8	5.5	V
T_A	Ambient operating temperature	-40	85	°C

Table 10. AC measurement conditions

Symbol	Parameter	Min.	Max.	Unit
C_L	Load capacitance	-	30	pF
-	Input rise and fall times	-	25	ns
-	Input pulse voltages	$0.2 V_{CC}$ to $0.8 V_{CC}$		V
-	Input and output timing reference voltages	$0.3 V_{CC}$ to $0.7 V_{CC}$		V

Figure 19. AC measurement I/O waveform

DT00825cV2

Table 11. Cycling performance by groups of four bytes

Symbol	Parameter	Test condition	Min.	Max.	Unit
Ncycle	Write cycle endurance ⁽¹⁾	$T_A \leq 25\text{ }^{\circ}\text{C}$, $V_{CC}(\text{min}) < V_{CC} < V_{CC}(\text{max})$	-	4,000,000	Write cycle ⁽²⁾
		$T_A = 85\text{ }^{\circ}\text{C}$, $V_{CC}(\text{min}) < V_{CC} < V_{CC}(\text{max})$	-	1,200,000	

1. The write cycle endurance is defined for groups of four data bytes located at addresses $[4*N, 4*N+1, 4*N+2, 4*N+3]$, where N is an integer. The write cycle endurance is defined by characterization and qualification.
2. A write cycle is executed when either a page write, a byte write, a WRSR, a WRID or an LID instruction is decoded. When using the byte write, the page write or the WRID instruction, refer also to [Section 6.11: Error correction code \(ECC x 4\) and write cycling](#).

Table 12. Memory cell data retention

Parameter	Test conditions	Min.	Unit
Data retention ⁽¹⁾	$T_A = 55\text{ }^{\circ}\text{C}$	40	Year

1. The data retention behaviour is checked in production, while the 40-year limit is defined from characterization and qualification results.

Table 13. Capacitance

Symbol	Parameter	Test conditions	Min.	Max.	Unit
$C_{OUT}^{(1)}$	Output capacitance (Q)	$V_{OUT} = 0\text{ V}$	-	8	pF
$C_{IN}^{(1)}$	Input capacitance (D)	$V_{IN} = 0\text{ V}$	-	8	pF
	Input capacitance (other pins)	$V_{IN} = 0\text{ V}$	-	6	pF

1. Specified by design – Not tested in production.

1. Values in inches are converted from mm and rounded to four decimal digits.
2. Dimension D does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm per side.
3. Dimension E1 does not include interlead flash or protrusions. Interlead flash or protrusions shall not exceed 0.25 mm per side.

Note: The package top may be smaller than the package bottom. Dimensions D and E1 are determined at the outermost extremes of the plastic body exclusive of mold flash, tie bar burrs, gate burrs, and interleads flash, but including any mismatch between the top and bottom of the plastic body. The measurement side for mold flash, protrusions, or gate burrs is the bottom side.
