

# enCoRe™ USB Combination Low-Speed USB and PS/2 Peripheral Controller

## Features

- enCoRe™ USB - enhanced Component Reduction
  - Internal oscillator eliminates the need for an external crystal or resonator
  - Interface can auto-configure to operate as PS/2 or USB without the need for external components to switch between modes (no General Purpose I/O [GPIO] pins needed to manage dual mode capability)
  - Internal 3.3 V regulator for USB pull-up resistor
  - Configurable GPIO for real-world interface without external components
- Flexible, cost-effective solution for applications that combine PS/2 and low-speed USB, such as mice, gamepads, joysticks, and many others.
- USB Specification Compliance
  - Conforms to USB Specification, Version 2.0
  - Conforms to USB HID Specification, Version 1.1
  - Supports one low-speed USB device address and three data endpoints
  - Integrated USB transceiver
  - 3.3 V regulated output for USB pull-up resistor
- 8-bit RISC microcontroller
  - Harvard architecture
  - 6-MHz external ceramic resonator or internal clock mode
  - 12-MHz internal CPU clock
  - Internal memory
  - 256 bytes of RAM
  - 8 Kbytes of EPROM
  - Interface can auto-configure to operate as PS/2 or USB
  - No external components for switching between PS/2 and USB modes
  - No GPIO pins needed to manage dual mode capability
- I/O ports
  - Up to 16 versatile GPIO pins, individually configurable
  - High current drive on any GPIO pin: 50 mA/pin current sink
  - Each GPIO pin supports high-impedance inputs, internal pull-ups, open drain outputs or traditional CMOS outputs
  - Maskable interrupts on all I/O pins
- SPI serial communication block
  - Master or slave operation
  - 2 Mbit/s transfers
- Four 8-bit Input Capture registers
  - Two registers each for two input pins
  - Capture timer setting with five prescaler settings
  - Separate registers for rising and falling edge capture
  - Simplifies interface to RF inputs for wireless applications
- Internal low-power wake-up timer during suspend mode
  - Periodic wake-up with no external components
- Optional 6-MHz internal oscillator mode
  - Allows fast start-up from suspend mode
- Watchdog Reset (WDR)
- Low-voltage Reset at 3.75 V
- Internal brown-out reset for suspend mode
- Improved output drivers to reduce EMI
- Operating voltage from 4.0V to 5.5VDC
- Operating temperature from 0°C to 70°C
- CY7C63723C available in 18-pin SOIC, 18-pin PDIP
- CY7C63743C available in 24-pin SOIC, 24-pin PDIP, 24-pin QSOP
- CY7C63722C available in DIE form
- Industry standard programmer support

**Errata:** For information on silicon errata, see "Errata" on page 53. Details include trigger conditions, devices affected, and proposed workaround.

## Functional Overview

### enCoRe USB—The New USB Standard

Cypress has reinvented its leadership position in the low-speed USB market with a new family of innovative microcontrollers. Introducing...enCoRe USB—"enhanced Component Reduction." Cypress has leveraged its design expertise in USB solutions to create a new family of low-speed USB microcontrollers that enables peripheral developers to design new products with a minimum number of components. At the heart of the enCoRe USB technology is the breakthrough design of a crystalless oscillator. By integrating the oscillator into our chip, an external crystal or resonator is no longer needed. We have also integrated other external components commonly found in low-speed USB applications such as pull-up resistors, wake-up circuitry, and a 3.3 V regulator. All of this adds up to a lower system cost.

The CY7C637xxC is an 8-bit RISC one-time-programmable (OTP) microcontroller. The instruction set has been optimized specifically for USB and PS/2 operations, although the microcontrollers can be used for a variety of other embedded applications.

The CY7C637xxC features up to 16 GPIO pins to support USB, PS/2 and other applications. The I/O pins are grouped into two ports (Port 0 to 1) where each pin can be individually configured as inputs with internal pull-ups, open drain outputs, or traditional CMOS outputs with programmable drive strength of up to 50 mA output drive. Additionally, each I/O pin can be used to generate a GPIO interrupt to the microcontroller. Note the GPIO interrupts all share the same "GPIO" interrupt vector.

The CY7C637xxC microcontrollers feature an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (6 MHz  $\pm$ 1.5%). Optionally, an external 6-MHz ceramic resonator can be used to provide a higher precision reference for USB operation. This clock generator reduces the clock-related noise emissions (EMI). The clock generator provides the 6- and 12-MHz clocks that remain internal to the microcontroller.

The CY7C637xxC has 8 Kbytes of EPROM and 256 bytes of data RAM for stack space, user variables, and USB FIFOs.

These parts include low-voltage reset logic, a Watchdog timer, a vectored interrupt controller, a 12-bit free-running timer, and capture timers. The low-voltage reset (LVR) logic detects when

power is applied to the device, resets the logic to a known state, and begins executing instructions at EPROM address 0x0000. LVR will also reset the part when  $V_{CC}$  drops below the operating voltage range. The Watchdog timer can be used to ensure the firmware never gets stalled for more than approximately 8 ms.

The microcontroller supports 10 maskable interrupts in the vectored interrupt controller. Interrupt sources include the USB Bus-Reset, the 128- $\mu$ s and 1.024-ms outputs from the free-running timer, three USB endpoints, two capture timers, an internal wake-up timer and the GPIO ports. The timers bits cause periodic interrupts when enabled. The USB endpoints interrupt after USB transactions complete on the bus. The capture timers interrupt whenever a new timer value is saved due to a selected GPIO edge event. The GPIO ports have a level of masking to select which GPIO inputs can cause a GPIO interrupt. For additional flexibility, the input transition polarity that causes an interrupt is programmable for each GPIO pin. The interrupt polarity can be either rising or falling edge <sup>[1]</sup>.

The free-running 12-bit timer clocked at 1 MHz provides two interrupt sources as noted above (128  $\mu$ s and 1.024 ms). The timer can be used to measure the duration of an event under firmware control by reading the timer at the start and end of an event, and subtracting the two values. The four capture timers save a programmable 8 bit range of the free-running timer when a GPIO edge occurs on the two capture pins (P0.0, P0.1).

The CY7C637xxC includes an integrated USB serial interface engine (SIE) that supports the integrated peripherals. The hardware supports one USB device address with three endpoints. The SIE allows the USB host to communicate with the function integrated into the microcontroller. A 3.3V regulated output pin provides a pull-up source for the external USB resistor on the D- pin.

The USB D+ and D- USB pins can alternately be used as PS/2 SCLK and SDATA signals, so that products can be designed to respond to either USB or PS/2 modes of operation. PS/2 operation is supported with internal pull-up resistors on SCLK and SDATA, the ability to disable the regulator output pin, and an interrupt to signal the start of PS/2 activity. No external components are necessary for dual USB and PS/2 systems, and no GPIO pins need to be dedicated to switching between modes. Slow edge rates operate in both modes to reduce EMI.

#### Note

1. **Errata:** When a falling edge interrupt is enabled for a GPIO pin, reading the GPIO Port 1 coincident to a rising edge of that GPIO signal may generate a false GPIO interrupt. In similar manner when a rising edge interrupt is enabled for a GPIO pin, reading the GPIO Port 1 coincident to a falling edge of that GPIO signal may generate a false GPIO interrupt. For more information, see the "Errata" on page 53.

## Pin Configurations

### Top View

## Pin Definitions

Name	I/O	CY7C63723C	CY7C63743C	CY7C63722C	Description
		18-Pin	24-Pin	25-Pad	
D-/SDATA, D+/SCLK	I/O	12 13	15 16	16 17	USB differential data lines (D- and D+), or PS/2 clock and data signals (SDATA and SCLK)
P0[7:0]	I/O	1, 2, 3, 4, 15, 16, 17, 18	1, 2, 3, 4, 21, 22, 23, 24	1, 2, 3, 4, 22, 23, 24, 25	GPIO Port 0 capable of sinking up to 50 mA/pin, or sinking controlled low or high programmable current. Can also source 2 mA current, provide a resistive pull-up, or serve as a high-impedance input. P0.0 and P0.1 provide inputs to Capture Timers A and B, respectively.
P1[7:0]	I/O	5, 14	5, 6, 7, 8, 17, 18, 19, 20	5, 6, 7, 8, 18, 19, 20, 21	IO Port 1 capable of sinking up to 50 mA/pin, or sinking controlled low or high programmable current. Can also source 2 mA current, provide a resistive pull-up, or serve as a high-impedance input.
XTALIN/P2.1	IN	9	12	13	6-MHz ceramic resonator or external clock input, or P2.1 input
XTALOUT	OUT	10	13	14	6-MHz ceramic resonator return pin or internal oscillator output
V <sub>PP</sub>		7	10	11	Programming voltage supply, ground for normal operation
V <sub>CC</sub>		11	14	15	Voltage supply
VREG/P2.0		8	11	12	Voltage supply for 1.3-k $\Omega$ USB pull-up resistor (3.3V nominal). Also serves as P2.0 input.
V <sub>SS</sub>		6	9	9, 10	Ground

## Programming Model

Refer to the *CYASM Assembler User's Guide* for more details on firmware operation with the CY7C637xxC microcontrollers.

### Program Counter (PC)

The 14-bit program counter (PC) allows access for up to 8 Kbytes of EPROM using the CY7C637xxC architecture. The program counter is cleared during reset, such that the first instruction executed after a reset is at address 0x0000. This instruction is typically a jump instruction to a reset handler that initializes the application.

The lower 8 bits of the program counter are incremented as instructions are loaded and executed. The upper six bits of the program counter are incremented by executing an XPAGE instruction. As a result, the last instruction executed within a 256-byte "page" of sequential code should be an XPAGE instruction. The assembler directive "XPAGEON" will cause the assembler to insert XPAGE instructions automatically. As instructions can be either one or two bytes long, the assembler may occasionally need to insert a NOP followed by an XPAGE for correct execution.

The program counter of the next instruction to be executed, carry flag, and zero flag are saved as two bytes on the program stack during an interrupt acknowledge or a CALL instruction. The program counter, carry flag, and zero flag are restored from the program stack only during a RETI instruction.

Please note the program counter cannot be accessed directly by the firmware. The program stack can be examined by reading SRAM from location 0x00 and up.

### 8-bit Accumulator (A)

The accumulator is the general-purpose, do everything register in the architecture where results are usually calculated.

### 8-bit Index Register (X)

The index register "X" is available to the firmware as an auxiliary accumulator. The X register also allows the processor to perform indexed operations by loading an index value into X.

### 8-bit Program Stack Pointer (PSP)

During a reset, the program stack pointer (PSP) is set to zero. This means the program "stack" starts at RAM address 0x00 and "grows" upward from there. Note that the program stack pointer is directly addressable under firmware control, using the MOV PSP,A instruction. The PSP supports interrupt service under hardware control and CALL, RET, and RETI instructions under firmware control.

During an interrupt acknowledge, interrupts are disabled and the program counter, carry flag, and zero flag are written as two bytes of data memory. The first byte is stored in the memory addressed by the program stack pointer, then the PSP is incremented. The second byte is stored in memory addressed by the program stack pointer and the PSP is incremented again. The net effect is to store the program counter and flags on the program "stack" and increment the program stack pointer by two.

The return from interrupt (RETI) instruction decrements the program stack pointer, then restores the second byte from memory addressed by the PSP. The program stack pointer is

decremented again and the first byte is restored from memory addressed by the PSP. After the program counter and flags have been restored from stack, the interrupts are enabled. The effect is to restore the program counter and flags from the program stack, decrement the program stack pointer by two, and re-enable interrupts.

The call subroutine (CALL) instruction stores the program counter and flags on the program stack and increments the PSP by two.

The return from subroutine (RET) instruction restores the program counter, but not the flags, from program stack and decrements the PSP by two.

Note that there are restrictions in using the JMP, CALL, and INDEX instructions across the 4-KByte boundary of the program memory. Refer to the *CYASM Assembler User's Guide* for a detailed description.

### 8-bit Data Stack Pointer (DSP)

The data stack pointer (DSP) supports PUSH and POP instructions that use the data stack for temporary storage. A PUSH instruction will pre-decrement the DSP, then write data to the memory location addressed by the DSP. A POP instruction will read data from the memory location addressed by the DSP, then post-increment the DSP.

During a reset, the Data Stack Pointer will be set to zero. A PUSH instruction when DSP equals zero will write data at the top of the data RAM (address 0xFF). This would write data to the memory area reserved for a FIFO for USB endpoint 0. In non-USB applications, this works fine and is not a problem.

For USB applications, the firmware should set the DSP to an appropriate location to avoid a memory conflict with RAM dedicated to USB FIFOs. The memory requirements for the USB endpoints are shown in [Data Memory Organization on page 10](#). For example, assembly instructions to set the DSP to 20h (giving 32 bytes for program and data stack combined) are shown below.

```
MOV A,20h    ; Move 20 hex into Accumulator (must be D8h
              ; or less to avoid USB FIFOs)
```

```
SWAP A,DSP   ; swap accumulator value into DSP register
```

### Address Modes

The CY7C637xxC microcontrollers support three addressing modes for instructions that require data operands: data, direct, and indexed.

#### Data

The "Data" address mode refers to a data operand that is actually a constant encoded in the instruction. As an example, consider the instruction that loads A with the constant 0x30:

```
■ MOV A, 30h
```

This instruction will require two bytes of code where the first byte identifies the "MOV A" instruction with a data operand as the second byte. The second byte of the instruction will be the constant "0xE8h". A constant may be referred to by name if a prior "EQU" statement assigns the constant value to the name. For example, the following code is equivalent to the example shown above.

■ DSPINIT: EQU 30h

■ MOV A,DSPINIT

#### Direct

“Direct” address mode is used when the data operand is a variable stored in SRAM. In that case, the one byte address of the variable is encoded in the instruction. As an example, consider an instruction that loads A with the contents of memory address location 0x10h:

■ MOV A, [10h]

In normal usage, variable names are assigned to variable addresses using “EQU” statements to improve the readability of the assembler source code. As an example, the following code is equivalent to the example shown above.

■ buttons: EQU 10h

■ MOV A, [buttons]

#### Indexed

“Indexed” address mode allows the firmware to manipulate arrays of data stored in SRAM. The address of the data operand is the sum of a constant encoded in the instruction and the contents of the “X” register. In normal usage, the constant will be the “base” address of an array of data and the X register will contain an index that indicates which element of the array is actually addressed.

■ array: EQU 10h

■ MOV X,3

■ MOV A, [x+array]

This would have the effect of loading A with the fourth element of the SRAM “array” that begins at address 0x10h. The fourth element would be at address 0x13h.

## Instruction Set Summary

Refer to the *CYASM Assembler User's Guide* for detailed information on these instructions. Note that conditional jump instructions (i.e., JC, JNC, JZ, JNZ) take five cycles if jump is taken, four cycles if no jump.

MNEMONIC	Operand	Opcode	Cycles	MNEMONIC	Operand	Opcode	Cycles
HALT		00	7	NOP		20	4

## Memory Organization

### Program Memory Organization<sup>[2]</sup>

Figure 1. Program Memory Space with Interrupt Vector Table

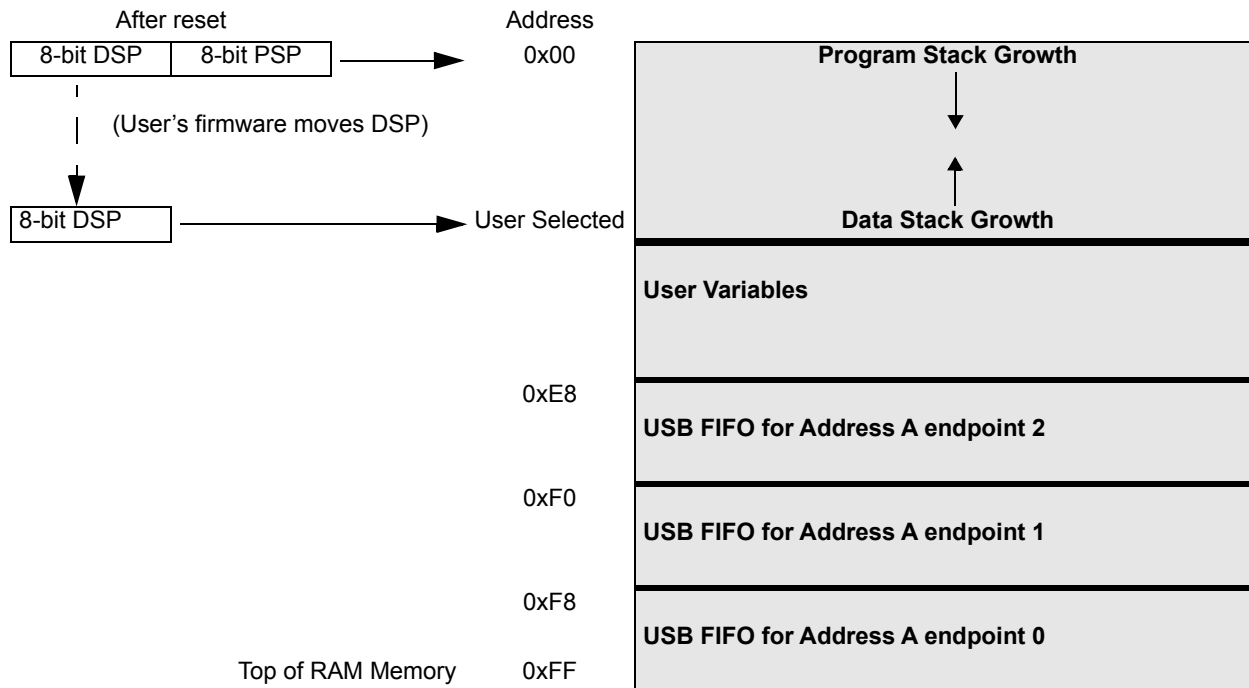

**Note**

2. The upper 32 bytes of the 8K PROM are reserved. Therefore, the user's program must not overwrite this space.

## Data Memory Organization

The CY7C637xxC microcontrollers provide 256 bytes of data RAM. In normal usage, the SRAM is partitioned into four areas: program stack, data stack, user variables and USB endpoint FIFOs as shown below.

**Figure 2. Data Memory Organization**

## I/O Register Summary

I/O registers are accessed via the I/O Read (IORD) and I/O Write (IOWR, IOWX) instructions. IORD reads the selected port into the accumulator. IOWR writes data from the accumulator to the selected port. Indexed I/O Write (IOWX) adds the contents of X to the address in the instruction to form the port address and writes data from the accumulator to the specified port. Note that

specifying address 0 with IOWX (e.g., IOWX 0h) means the I/O port is selected solely by the contents of X.

**Note:** All bits of all registers are cleared to all zeros on reset, except the Processor Status and Control Register (Figure 34). All registers not listed are reserved, and should never be written by firmware. All bits marked as reserved should always be written as 0 and be treated as undefined by reads.

**Table 1. I/O Register Summary**

Register Name	I/O Address	Read/Write	Function	Fig
Port 0 Data	0x00	R/W	GPIO Port 0	7
Port 1 Data	0x01	R/W	GPIO Port 1	8
Port 2 Data	0x02	R	Auxiliary input register for D+, D-, VREG, XTALIN	
Port 0 Interrupt Enable	0x04	W	Interrupt enable for pins in Port 0

## Clocking

The chip can be clocked from either the internal on-chip clock, or from an oscillator based on an external resonator/crystal, as shown in Figure 3. No additional capacitance is included on chip at the XTALIN/OUT pins. Operation is controlled by the Clock Configuration Register, Figure 4.

Figure 3. Clock Oscillator On-chip Circuit

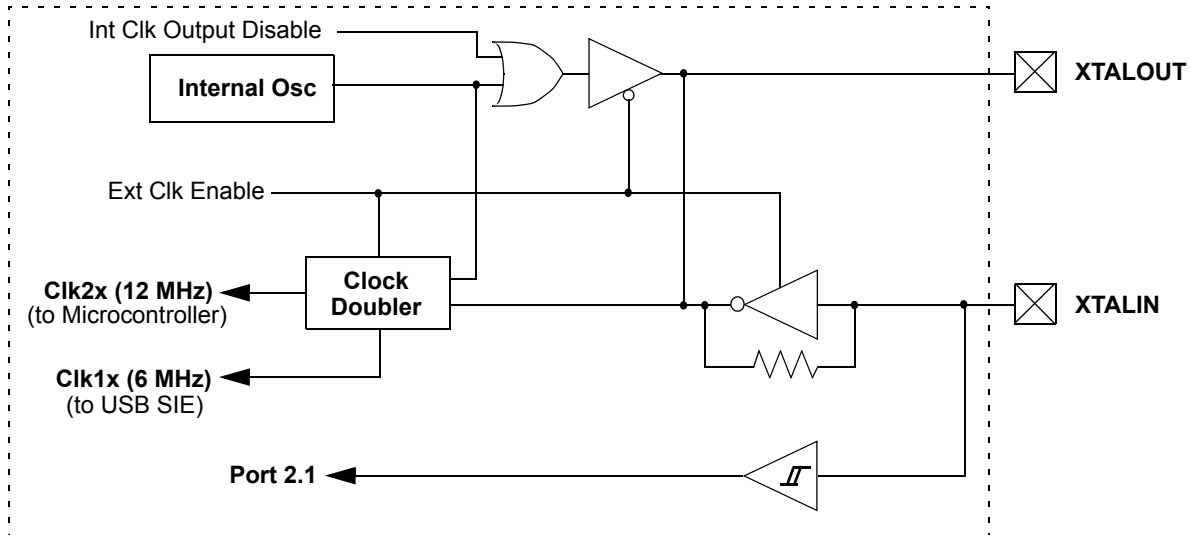

Figure 4. Clock Configuration Register (Address 0xF8)

Bit #	7	6	5	4	3	2	1	0
Bit Name	Ext. Clock Resume Delay	Wake-up Timer Adjust Bit [2:0]			Low-voltage Reset Disable	Precision USB Clocking Enable	Internal Clock Output Disable	External Oscillator Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

### Bit 7: Ext. Clock Resume Delay

External Clock Resume Delay bit selects the delay time when switching to the external oscillator from the internal oscillator mode, or when waking from suspend mode with the external oscillator enabled.

1 = 4 ms delay.

0 = 128  $\mu$ s delay.

The delay gives the oscillator time to start up. The shorter time is adequate for operation with ceramic resonators, while the longer time is preferred for start-up with a crystal. (These times **do not include** an initial oscillator start-up time which depends on the resonating element. This time is typically 50–100  $\mu$ s for ceramic resonators and 1–10 ms for crystals). Note that this bit only selects the delay time for the external clock mode. When waking from suspend mode with the internal oscillator (Bit 0 is LOW), the delay time is only 8  $\mu$ s in addition to a delay of approximately 1  $\mu$ s for the oscillator to start.

### Bit [6:4]: Wake-up Timer Adjust Bit [2:0]

The Wake-up Timer Adjust Bits are used to adjust the Wake-up timer period.

If the Wake-up interrupt is enabled in the Global Interrupt Enable Register, the microcontroller will generate wake-up interrupts periodically. The frequency of these periodical wake-up interrupts is adjusted by setting the Wake-up Timer Adjust Bit [2:0], as described in [Wake-up Timer on page 16](#). One common use of the wake-up interrupts is to generate periodical wake-up events during suspend mode to check for changes, such as looking for movement in a mouse, while maintaining a low average power.

### Bit 3: Low-voltage Reset Disable

When  $V_{CC}$  drops below  $V_{LVR}$  (see [DC Characteristics on page 42](#) for the value of  $V_{LVR}$ ) and the Low-voltage Reset circuit is enabled, the microcontroller enters a partial suspend state for a period of  $t_{START}$  (see [Switching Characteristics on](#)

page 44 for the value of  $t_{START}$ ). Program execution begins from address 0x0000 after this  $t_{START}$  delay period. This provides time for  $V_{CC}$  to stabilize before the part executes code. See [Low-voltage Reset \(LVR\) on page 14](#) for more details.

1 = Disables the LVR circuit.

0 = Enables the LVR circuit.

## Bit 2: Precision USB Clocking Enable

The Precision USB Clocking Enable only affects operation in internal oscillator mode. **In that mode, this bit must be set to 1 to cause the internal clock to automatically precisely tune to USB timing requirements (6 MHz  $\pm$ 1.5%).** The frequency may have a looser initial tolerance at power-up, but all USB transmissions from the chip will meet the USB specification.

1 = Enabled. The internal clock accuracy is **6 MHz  $\pm$ 1.5%** after USB traffic is received.

0 = Disabled. The internal clock accuracy is 6 MHz  $\pm$ 5%.

## Bit 1: Internal Clock Output Disable

The Internal Clock Output Disable is used to keep the internal clock from driving out to the XTALOUT pin. This bit has no effect in the external oscillator mode.

1 = Disable internal clock output. XTALOUT pin will drive HIGH.

0 = Enable the internal clock output. The internal clock is driven out to the XTALOUT pin.

## Bit 0: External Oscillator Enable

At power-up, the chip operates from the internal clock by default. Setting the External Oscillator Enable bit HIGH disables the internal clock, and halts the part while the external resonator/crystal oscillator is started. Clearing this bit has no immediate effect, although the state of this bit is used when waking out of suspend mode to select between internal and external clock. In internal clock mode, XTALIN pin will be configured as an input with a weak pull-down and can be used as a GPIO input (P2.1).

1 = Enable the external oscillator. The clock is switched to external clock mode, as described in [Internal/External Oscillator Operation on page 13](#).

0 = Enable the internal oscillator.

## Internal/External Oscillator Operation

The internal oscillator provides an operating clock, factory set to a nominal frequency of 6 MHz. This clock requires no external components. At power-up, the chip operates from the internal clock. In this mode, the internal clock is buffered and driven to the XTALOUT pin by default, and the state of the XTALIN pin can be read at Port 2.1. While the internal clock is enabled, its output can be disabled at the XTALOUT pin by setting the Internal Clock Output Disable bit of the Clock Configuration Register.

Setting the External Oscillator Enable bit of the Clock Configuration Register HIGH disables the internal clock, and halts the part while the external resonator/crystal oscillator is started. The steps involved in switching from Internal to External Clock mode are as follows:

1. At reset, chip begins operation using the internal clock.
2. Firmware sets Bit 0 of the Clock Configuration Register. For example,  

```
mov A, 1h      ; Set Bit 0 HIGH (External Oscillator Enable bit). Bit 7 cleared gives faster start-up
iowr F8h      ; Write to Clock Configuration Register
```
3. Internal clocking is halted, the internal oscillator is disabled, and the external clock oscillator is enabled.
4. After the external clock becomes stable, chip clocks are re-enabled using the external clock signal. (Note that the time for the external clock to become stable depends on the external resonating device; see next section.)
5. After an additional delay the CPU is released to run. This delay depends on the state of the Ext. Clock Resume Delay bit of the Clock Configuration Register. The time is 128  $\mu$ s if the bit is 0, or 4 ms if the bit is 1.
6. Once the chip has been set to external oscillator, it can only return to internal clock when waking from suspend mode. Clearing bit 0 of the Clock Configuration Register will not re-enable internal clock mode until suspend mode is entered. See [Suspend Mode on page 15](#) for more details on suspend mode operation.

If the Internal Clock is enabled, the XTALIN pin can serve as a general purpose input, and its state can be read at Port 2, Bit 1 (P2.1). Refer to [Figure 13 on page 19](#) for the Port 2 Data Register. In this mode, there is a weak pull-down at the XTALIN pin. This input cannot provide an interrupt source to the CPU.

## External Oscillator

The user can connect a low-cost ceramic resonator or an external oscillator to the XTALIN/XTALOUT pins to provide a precise reference frequency for the chip clock, as shown in [Figure 3 on page 12](#). The external components required are a ceramic resonator or crystal and any associated capacitors. To run from the external resonator, the External Oscillator Enable bit of the Clock Configuration Register must be set to 1, as explained in the previous section.

Start-up times for the external oscillator depend on the resonating device. Ceramic resonator based oscillators typically start in less than 100  $\mu$ s, while crystal based oscillators take longer, typically 1 to 10 ms. Board capacitance should be minimized on the XTALIN and XTALOUT pins by keeping the traces as short as possible.

An external 6-MHz clock can be applied to the XTALIN pin if the XTALOUT pin is left open.

## Reset

The USB Controller supports three types of resets. The effects of the reset are listed below. The reset types are:

1. Low-voltage Reset (LVR)
2. Brown Out Reset (BOR)
3. Watchdog Reset (WDR)

The occurrence of a reset is recorded in the Processor Status and Control Register ([Figure 34 on page 30](#)). Bits 4 (Low-voltage or Brown-out Reset bit) and 6 (Watchdog Reset bit) are used to

record the occurrence of LVR/BOR and WDR respectively. The firmware can interrogate these bits to determine the cause of a reset.

The microcontroller begins execution from ROM address 0x0000 after a LVR, BOR, or WDR reset. Although this looks like interrupt vector 0, there is an important difference. Reset processing does NOT push the program counter, carry flag, and zero flag onto program stack. Attempting to execute either a RET or RETI in the reset handler will cause unpredictable execution results.

The following events take place on reset. More details on the various resets are given in the following sections.

1. All registers are reset to their default states (all bits cleared, except in Processor Status and Control Register).
2. GPIO and USB pins are set to high-impedance state.
3. The VREG pin is set to high-impedance state.
4. Interrupts are disabled.
5. USB operation is disabled and must be enabled by firmware if desired, as explained in [USB Port Status and Control on page 19](#).
6. For a BOR or LVR, the external oscillator is disabled and Internal Clock mode is activated, followed by a time-out period  $t_{START}$  for  $V_{CC}$  to stabilize. A WDR does not change the clock mode, and there is no delay for  $V_{CC}$  stabilization on a WDR. Note that the External Oscillator Enable (Bit 0, [Figure 4 on page 12](#)) will be cleared by a WDR, but it does not take effect until suspend mode is entered.
7. The Program Stack Pointer (PSP) and Data Stack Pointer (DSP) reset to address 0x00. Firmware should move the DSP for USB applications, as explained in [8-bit Data Stack Pointer \(DSP\) on page 6](#).
8. Program execution begins at address 0x0000 after the appropriate time-out period.

### Low-voltage Reset (LVR)

When  $V_{CC}$  is first applied to the chip, the internal oscillator is started and the Low-voltage Reset is initially enabled by default. At the point where  $V_{CC}$  has risen above  $V_{LVR}$  (see [DC Characteristics on page 42](#) for the value of  $V_{LVR}$ ), an internal counter starts counting for a period of  $t_{START}$  (see [Switching Characteristics on page 44](#) for the value of  $t_{START}$ ). During this  $t_{START}$  time, the microcontroller enters a partial suspend state to wait for  $V_{CC}$  to stabilize before it begins executing code from address 0x0000.

As long as the LVR circuit is enabled, this reset sequence repeats whenever the  $V_{CC}$  pin voltage drops below  $V_{LVR}$ . The LVR can be disabled by firmware by setting the Low-voltage Reset Disable bit in the Clock Configuration Register ([Figure 4 on page 12](#)). In addition, the LVR is automatically disabled in suspend mode to save power. If the LVR was enabled before entering suspend mode, it becomes active again once the suspend mode ends.

When LVR is disabled during normal operation (i.e., by writing '0' to the Low-voltage Reset Disable bit in the Clock Configuration Register), the chip may enter an unknown state if  $V_{CC}$  drops below  $V_{LVR}$ . Therefore, LVR should be enabled at all times during normal operation. If LVR is disabled (i.e., by firmware or during suspend mode), a secondary low-voltage monitor, BOR, becomes active, as described in the next section. The LVR/BOR Reset bit of the Processor Status and Control Register ([Figure 34 on page 30](#)), is set to '1' if either a LVR or BOR has occurred.

### Brown Out Reset (BOR)

The Brown Out Reset (BOR) circuit is always active and behaves like the POR. BOR is asserted whenever the  $V_{CC}$  voltage to the device is below an internally defined trip voltage of approximately 2.5 V. The BOR re-enables LVR. That is, once  $V_{CC}$  drops and trips BOR, the part remains in reset until  $V_{CC}$  rises above  $V_{LVR}$ . At that point, the  $t_{START}$  delay occurs before normal operation resumes, and the microcontroller starts executing code from address 0x00 after the  $t_{START}$  delay.

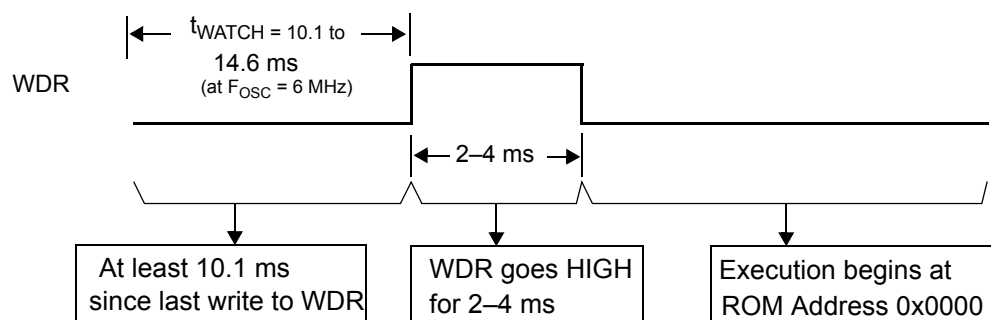

In suspend mode, only the BOR detection is active, giving a reset if  $V_{CC}$  drops below approximately 2.5 V. Since the device is suspended and code is not executing, this lower reset voltage is safe for retaining the state of all registers and memory. Note that in suspend mode, LVR is disabled as discussed in [Low-voltage Reset \(LVR\)](#).

### Watchdog Reset (WDR)

The Watchdog Timer Reset (WDR) occurs when the internal Watchdog timer rolls over. Writing any value to the write-only Watchdog Reset Register at address 0x26 will clear the timer. The timer will roll over and WDR will occur if it is not cleared within  $t_{WATCH}$  (see [Figure 5](#)) of the last clear. Bit 6 (Watchdog Reset bit) of the Processor Status and Control Register is set to record this event (see [Processor Status and Control Register on page 30](#) for more details). A Watchdog Timer Reset typically lasts for 2–4 ms, after which the microcontroller begins execution at ROM address 0x0000.

**Figure 5. Watchdog Reset (WDR, Address 0x26)**

## Suspend Mode

The CY7C637xxC parts support a versatile low-power suspend mode. In suspend mode, only an enabled interrupt or a LOW state on the D-/SDATA pin will wake the part. Two options are available. For lowest power, all internal circuits can be disabled, so only an external event will resume operation. Alternatively, a low-power internal wake-up timer can be used to trigger the wake-up interrupt. This timer is described in [Wake-up Timer on page 16](#), and can be used to periodically poll the system to check for changes, such as looking for movement in a mouse, while maintaining a low average power.

The CY7C637xxC is placed into a low-power state by setting the Suspend bit of the Processor Status and Control Register ([Figure 34](#)). All logic blocks in the device are turned off except the GPIO interrupt logic, the D-/SDATA pin input receiver, and (optionally) the wake-up timer. The clock oscillators, as well as the free-running and Watchdog timers are shut down. Only the occurrence of an enabled GPIO interrupt, wake-up interrupt, SPI slave interrupt, or a LOW state on the D-/SDATA pin will wake the part from suspend (D- LOW indicates non-idle USB activity). Once one of these resuming conditions occurs, clocks will be restarted and the device returns to full operation after the oscillator is stable and the selected delay period expires. This delay period is determined by selection of internal versus external clock, and by the state of the Ext. Clock Resume Delay as explained in [Clocking Mode on Wake-up from Suspend on page 15](#).

In suspend mode, any enabled and pending interrupt will wake the part up. The state of the Interrupt Enable Sense bit (Bit 2, [Figure 34 on page 30](#)) does not have any effect. As a result, any interrupts not intended for waking from suspend should be disabled through the Global Interrupt Enable Register and the USB End Point Interrupt Enable Register ([Interrupts](#)).

If a resuming condition exists when the suspend bit is set, the part will still go into suspend and then awake after the appropriate delay time. The Run bit in the Processor Status and Control Register must be set for the part to resume out of suspend.

Once the clock is stable and the delay time has expired, the microcontroller will execute the instruction following the I/O write that placed the device into suspend mode before servicing any interrupt requests.

To achieve the lowest possible current during suspend mode, all I/O should be held at either  $V_{CC}$  or ground. In addition, the GPIO *bit* interrupts ([Figure on page 34](#) and [Figure on page 34](#)) should be disabled for any pins that are not being used for a wake-up interrupt. This should be done even if the main GPIO Interrupt Enable ([Figure 35 on page 32](#)) is off.

Typical code for entering suspend is shown below:

```

...           ; All GPIO set to low-power state (no floating
...           ; pins, and bit interrupts disabled unless using
...           ; for wake-up)
...           ; Enable GPIO and/or wake-up timer
...           ; interrupts if desired for wake-up
...           ; Select clock mode for wake-up (see Clocking
...           ; Mode on Wake-up from Suspend on page
...           ; 15)
mov a, 09h    ; Set suspend and run bits
iowr FFh     ; Write to Status and Control Register – Enter
              ; suspend, wait for GPIO/wake-up interrupt or
              ; USB activity
nop          ; This executes before any ISR
...          ; Remaining code for exiting suspend routine
  
```

## Clocking Mode on Wake-up from Suspend

When exiting suspend on a wake-up event, the device can be configured to run in either Internal or External Clock mode. The mode is selected by the state of the External Oscillator Enable bit in the Clock Configuration Register ([Figure 4 on page 12](#)). Using the Internal Clock saves the external oscillator start-up time and keeps that oscillator off for additional power savings. The external oscillator mode can be activated when desired, similar to operation at power-up.

The sequence of events for these modes is as follows:

### Wake in Internal Clock Mode:

1. Before entering suspend, clear bit 0 of the Clock Configuration Register. This selects Internal clock mode after suspend.
2. Enter suspend mode by setting the suspend bit of the Processor Status and Control Register.
3. After a wake-up event, the internal clock starts immediately (within 2  $\mu\text{s}$ ).
4. A time-out period of 8  $\mu\text{s}$  passes, and then firmware execution begins.

- At some later point, to activate External Clock mode, set bit 0 of the Clock Configuration Register. This halts the internal clocks while the external clock becomes stable. After an additional time-out (128  $\mu$ s or 4 ms, see [Clocking Mode on Wake-up from Suspend on page 15](#)), firmware execution resumes.

#### Wake in External Clock Mode:

- Before entering suspend, the external clock must be selected by setting bit 0 of the Clock Configuration Register. Make sure this bit is still set when suspend mode is entered. This selects External clock mode after suspend.
- Enter suspend mode by setting the suspend bit of the Processor Status and Control Register.
- After a wake-up event, the external oscillator is started. The clock is monitored for stability (this takes approximately 50–100  $\mu$ s with a ceramic resonator).
- After an additional time-out period (128  $\mu$ s or 4 ms, see [Clocking Mode on Wake-up from Suspend on page 15](#)), firmware execution resumes.

#### Wake-up Timer

The wake-up timer runs whenever the wake-up interrupt is enabled, and is turned off whenever that interrupt is disabled. Operation is independent of whether the device is in suspend mode or if the global interrupt bit is enabled. Only the Wake-up Timer Interrupt Enable bit ([Figure 35 on page 32](#)) controls the wake-up timer.

Once this timer is activated, it will give interrupts after its time-out period (see below). These interrupts continue periodically until the interrupt is disabled. Whenever the interrupt is disabled, the

wake-up timer is reset, so that a subsequent enable always results in a full wake-up time.

The wake-up timer can be adjusted by the user through the Wake-up Timer Adjust bits in the Clock Configuration Register ([Figure 4 on page 12](#)). These bits clear on reset. In addition to allowing the user to select a range for the wake-up time, a firmware algorithm can be used to tune out initial process and operating condition variations in this wake-up time. This can be done by timing the wake-up interrupt time with the accurate 1.024-ms timer interrupt, and adjusting the Timer Adjust bits accordingly to approximate the desired wake-up time.

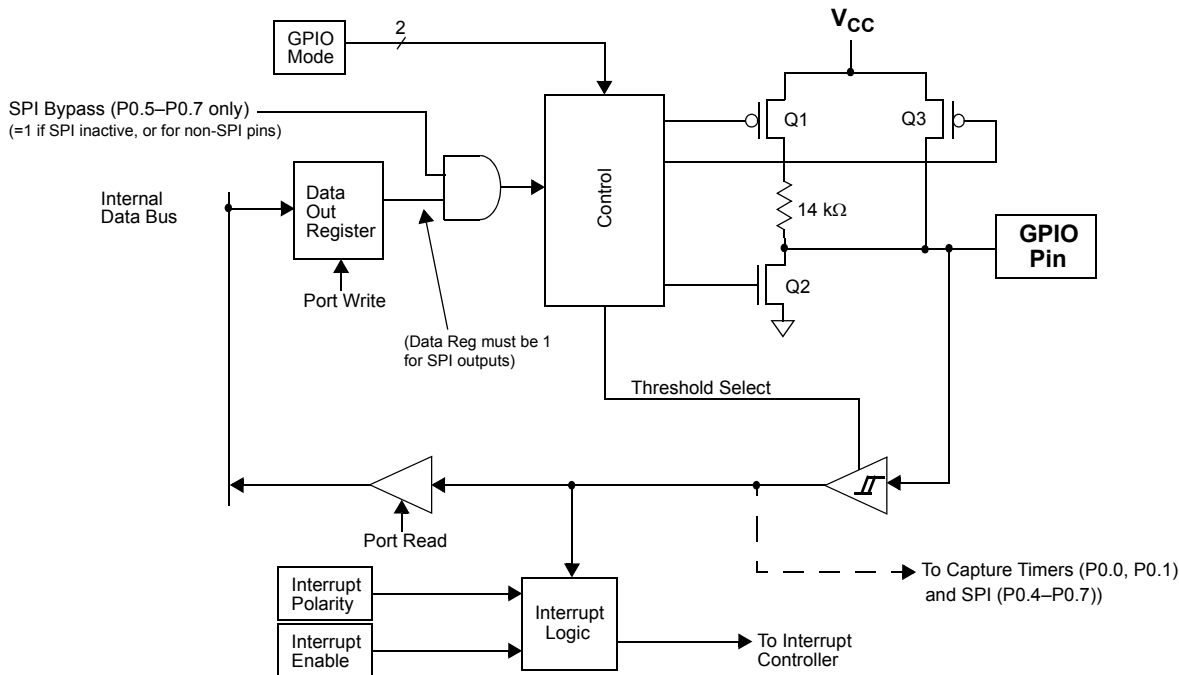

**Table 2. Wake-up Timer Adjust Settings**

Adjust Bits [2:0] (Bits [6:4] in <a href="#">Figure 4 on page 12</a> )	Wakeup Time
000 (reset state)	1 * $t_{WAKE}$
001	2 * $t_{WAKE}$
010	4 * $t_{WAKE}$
011	8 * $t_{WAKE}$
100	16 * $t_{WAKE}$
101	32 * $t_{WAKE}$
110	64 * $t_{WAKE}$
111	128 * $t_{WAKE}$
See <a href="#">Switching Characteristics on page 44</a> for the value of $t_{WAKE}$	

## General Purpose I/O Ports

Ports 0 and 1 provide up to 16 versatile GPIO pins that can be read or written (the number of pins depends on package type). [Figure 6](#) shows a diagram of a GPIO port pin.

**Figure 6. Block Diagram of GPIO Port (one pin shown)**

Port 0 is an 8-bit port; Port 1 contains either 2 bits, P1.1-P1.0 in the CY7C63723C, or all 8 bits, P1.7-P1.0 in the CY7C63743C parts. Each bit can also be selected as an interrupt source for the microcontroller, as explained in [Interrupt Sources on page 32](#).

The data for each GPIO pin is accessible through the Port Data register. Writes to the Port Data register store outgoing data state for the port pins, while reads from the Port Data register return the actual logic value on the port pins, not the Port Data register contents.

Each GPIO pin is configured independently. The driving state of each GPIO pin is determined by the value written to the pin's Data Register and by two associated pin's Mode0 and Mode1 bits.

The Port 0 Data Register is shown in [Figure 7 on page 17](#), and the Port 1 Data Register is shown in [Figure 8 on page 17](#). The Mode0 and Mode1 bits for the two GPIO ports are given in [Figure 9 on page 17](#) through [Figure 12 on page 18](#).

**Figure 7. Port 0 Data (Address 0x00)**

Bit #	7	6	5	4	3	2	1	0

- 0 = Port Pin Mode 0 is logic LOW

**Figure 12. GPIO Port 1 Mode1 Register (Address 0x0D)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	P1[7:0] Mode1							
Read/Write	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

#### Bit [7:0]: P1[7:0] Mode 1

- 1 = Port Pin Mode 1 is logic HIGH
- 0 = Port Pin Mode 1 is logic LOW

Each pin can be independently configured as high-impedance inputs, inputs with internal pull-ups, open drain outputs, or traditional CMOS outputs with selectable drive strengths.

The driving state of each GPIO pin is determined by the value written to the pin's Data Register and by its associated Mode0 and Mode1 bits. *Table 3* lists the configuration states based on these bits. The GPIO ports default on reset to all Data and Mode Registers cleared, so the pins are all in a high-impedance state. The available GPIO output drive strength are:

#### ■ Hi-Z Mode (Mode1 = 0 and Mode0 = 0)

Q1, Q2, and Q3 ([Figure 6 on page 17](#)) are OFF. The GPIO pin is not driven internally. Performing a read from the Port Data Register return the actual logic value on the port pins.

#### ■ Low Sink Mode (Mode1 = 1, Mode0 = 0, and the pin's Data Register = 0)

Q1 and Q3 are OFF. Q2 is ON. The GPIO pin is capable of sinking 2 mA of current.

#### ■ Medium Sink Mode (Mode1 = 0, Mode0 = 1, and the pin's Data Register = 0)

Q1 and Q3 are OFF. Q2 is ON. The GPIO pin is capable of sinking 8 mA of current.

#### ■ High Sink Mode (Mode1 = 1, Mode0 = 1, and the pin's Data Register = 0)

Q1 and Q3 are OFF. Q2 is ON. The GPIO pin is capable of sinking 50 mA of current.

#### ■ High Drive Mode (Mode1 = 0 or 1, Mode0 = 1, and the pin's Data Register = 1)

Q1 and Q2 are OFF. Q3 is ON. The GPIO pin is capable of sourcing 2 mA of current.

#### ■ Resistive Mode (Mode1 = 1, Mode0 = 0, and the pin's Data Register = 1)

Q2 and Q3 are OFF. Q1 is ON. The GPIO pin is pulled up with an internal 14-kΩ resistor.

Note that open drain mode can be achieved by fixing the Data and Mode1 Registers LOW, and switching the Mode0 register.

Input thresholds are CMOS, or TTL as shown in the table (See [DC Characteristics on page 42](#) for the input threshold voltage in TTL or CMOS modes). Both input modes include hysteresis to minimize noise sensitivity. In suspend mode, if a pin is used for a wake-up interrupt using an external R-C circuit, CMOS mode is preferred for lowest power.

**Table 3. Ports 0 and 1 Output Control Truth Table**

Data Register	Mode1	Mode0	Output Drive Strength	Input Threshold
0	0	0	Hi-Z	CMOS
1			Hi-Z	TTL
0	0	1	Medium (8 mA) Sink	CMOS
1			High Drive	CMOS
0	1	0	Low (2 mA) Sink	CMOS
1			Resistive	CMOS
0	1	1	High (50 mA) Sink	CMOS
1			High Drive	CMOS

#### Auxiliary Input Port

Port 2 serves as an auxiliary input port as shown in [Figure 13](#). The Port 2 inputs all have TTL input thresholds.

**Figure 13. Port 2 Data Register (Address 0x02)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Reserved		D+ (SCLK) State	D- (SDATA) State	Reserved		P2.1 (Internal Clock Mode Only)	P2.0 VREG Pin State
Read/Write	-	-	R	R	-	-	R	R
Reset	0	0	0	0	0	0	0	0

**Bit [7:6]:** Reserved

#### **Bit [5:4]: D+ (SCLK) and D- (SDATA) States**

The state of the D+ and D- pins can be read at Port 2 Data Register. Performing a read from the port pins returns their logic values.

1 = Port Pin is logic HIGH

0 = Port Pin is logic LOW

**Bit [3:2]:** Reserved

#### **Bit 1: P2.1 (Internal Clock Mode Only)**

In the Internal Clock mode, the XTALIN pin can serve as a general purpose input, and its state can be read at Port 2, Bit 1 (P2.1). See [Internal/External Oscillator Operation on page 13](#) for more details.

1 = Port Pin is logic HIGH

0 = Port Pin is logic LOW

#### **Bit 0: P2.0/VREG Pin State**

In PS/2 mode, the VREG pin can be used as an input and its state can be read at port P2.0. [USB Regulator Output on page 22](#) for more details.

1 = Port Pin is logic HIGH

0 = Port Pin is logic LOW

## **USB Serial Interface Engine (SIE)**

The SIE allows the microcontroller to communicate with the USB host. The SIE simplifies the interface between the microcontroller and USB by incorporating hardware that handles the following USB bus activity independently of the microcontroller:

- Translate the encoded received data and format the data to be transmitted on the bus.
- CRC checking and generation. Flag the microcontroller if errors exist during transmission.
- Address checking. Ignore the transactions not addressed to the device.
- Send appropriate ACK/NAK/STALL handshakes.

- Token type identification (SETUP, IN, or OUT). Set the appropriate token bit once a valid token is received.

- Place valid received data in the appropriate endpoint FIFOs.

- Send and update the data toggle bit (Data1/0).

- Bit stuffing/unstuffing.

Firmware is required to handle the rest of the USB interface with the following tasks:

- Coordinate enumeration by decoding USB device requests.

- Fill and empty the FIFOs.

- Suspend/Resume coordination.

- Verify and select Data toggle values.

## **USB Enumeration**

A typical USB enumeration sequence is shown below. In this description, 'Firmware' refers to embedded firmware in the CY7C637xxC controller.

1. The host computer sends a SETUP packet followed by a DATA packet to USB address 0 requesting the Device descriptor.
2. Firmware decodes the request and retrieves its Device descriptor from the program memory tables.
3. The host computer performs a control read sequence and Firmware responds by sending the Device descriptor over the USB bus, via the on-chip FIFO.
4. After receiving the descriptor, the host sends a SETUP packet followed by a DATA packet to address 0 assigning a new USB address to the device.
5. Firmware stores the new address in its USB Device Address Register after the no-data control sequence completes.
6. The host sends a request for the Device descriptor using the new USB address.
7. Firmware decodes the request and retrieves the Device descriptor from program memory tables.
8. The host performs a control read sequence and Firmware responds by sending its Device descriptor over the USB bus.
9. The host generates control reads from the device to request the Configuration and Report descriptors.
10. Once the device receives a Set Configuration request, its functions may now be used.
11. Firmware should take appropriate action for Endpoint 1 and/or 2 transactions, which may occur from this point.

## **USB Port Status and Control**

USB status and control is regulated by the USB Status and Control Register as shown in [Figure 14](#).

**Figure 14. USB Status and Control Register (Address 0x1F)**

Bit #	7	6	5	4	3	2:0
<b>Bit Name</b>	PS/2 Pull-up Enable	VREG Enable	USB Reset-PS/2 Activity Interrupt Mode	Reserved	USB Bus Activity	D+/D- Forcing Bit
<b>Read/Write</b>	R/W	R/W	R/W	-	R/W	R/W
<b>Reset</b>	0	0	0	0	0	0 0 0

**Bit 7: PS/2 Pull-up Enable**

This bit is used to enable the internal PS/2 pull-up resistors on the SDATA and SCLK pins. Normally the output high level on these pins is  $V_{CC}$ , but note that the output will be clamped to approximately 1 Volt above  $V_{REG}$  if the VREG Enable bit is set, or if the Device Address is enabled (bit 7 of the USB Device Address Register, [Figure 15 on page 21](#)).

1 = Enable PS/2 Pull-up resistors. The SDATA and SCLK pins are pulled up internally to  $V_{CC}$  with two resistors of approximately 5 k $\Omega$  (see [DC Characteristics on page 42](#) for the value of  $R_{PS2}$ ).

0 = Disable PS/2 Pull-up resistors.

**Bit 6: VREG Enable**

A 3.3 V voltage regulator is integrated on chip to provide a voltage source for a 1.5-k $\Omega$  pull-up resistor connected to the D- pin as required by the USB Specification. Note that the VREG output has an internal series resistance of approximately 200 $\Omega$ , the external pull-up resistor required is approximately 1.3-k $\Omega$  (see [Figure 19 on page 23](#)).

1 = Enable the 3.3 V output voltage on the VREG pin.

0 = Disable. The VREG pin can be configured as an input.

**Bit 5: USB-PS/2 Interrupt Select**

This bit allows the user to select whether an USB bus reset interrupt or a PS/2 activity interrupt will be generated when the interrupt conditions are detected.

1 = PS/2 interrupt mode. A PS/2 activity interrupt will occur if the SDATA pin is continuously LOW for 128 to 256  $\mu$ s.

0 = USB interrupt mode (default state). In this mode, a USB bus reset interrupt will occur if the single ended zero (SE0, D- and D+ are LOW) exists for 128 to 256  $\mu$ s.

See [Interrupt Sources on page 32](#) for more details.

**Bit 4:** Reserved. Must be written as a '0'.

**Bit 3: USB Bus Activity**

The Bus Activity bit is a "sticky" bit that detects any non-idle USB event has occurred on the USB bus. Once set to HIGH by the SIE to indicate the bus activity, this bit retains its logical HIGH value until firmware clears it. Writing a '0' to this bit clears it; writing a '1' preserves its value. The user firmware should check and clear this bit periodically to detect any loss of bus activity. Firmware can clear the Bus Activity bit, but only the SIE can set it. The 1.024-ms timer interrupt service routine is normally used to check and clear the Bus Activity bit.

1 = There has been bus activity since the last time this bit was cleared. This bit is set by the SIE.

0 = No bus activity since last time this bit was cleared (by firmware).

**Bit [2:0]: D+/D- Forcing Bit [2:0]**

Forcing bits allow firmware to directly drive the D+ and D- pins, as shown in [Table 4](#). Outputs are driven with controlled edge rates in these modes for low EMI. For forcing the D+ and D- pins in USB mode, D+/D- Forcing Bit 2 should be 0. Setting D+/D- Forcing Bit 2 to '1' puts both pins in an open-drain mode, preferred for applications such as PS/2 or LED driving.

**Table 4. Control Modes to Force D+/D- Outputs**

D+/D- Forcing Bit [2:0]	Control Action	Application
000	Not forcing (SIE controls driver)	Any Mode
001	Force K (D+ HIGH, D- LOW)	USB Mode
010	Force J (D+ LOW, D- HIGH)	
011	Force SE0 (D- LOW, D+ LOW)	
100	Force D- LOW, D+ LOW	PS/2 Mode <sup>[3]</sup>
101	Force D- LOW, D+ HiZ	
110	Force D- HiZ, D+ LOW	
111	Force D- HiZ, D+ HiZ	

**USB Device**

The CY7C637xxC supports one USB Device Address with three endpoints: EP0, EP1, and EP2.

**USB Address Register**

The USB Device Address Register contains a 7-bit USB address and one bit to enable USB communication. This register is cleared during a reset, setting the USB device address to zero and marking this address as disabled. [Figure 15](#) shows the format of the USB Address Register.

**Note**

- For PS/2 operation, the D+/D- Forcing Bit [2:0] = 111b mode must be set initially (one time only) before using the other PS/2 force modes

**Figure 15. USB Device Address Register (Address 0x10)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Device Address Enable	Device Address						
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

In either USB or PS/2 mode, this register is cleared by both hardware resets and the USB bus reset. See [Interrupt Sources on page 32](#) for more information on the USB Bus Reset – PS/2 interrupt.

**Bit 7: Device Address Enable**

This bit must be enabled by firmware before the serial interface engine (SIE) will respond to USB traffic at the address specified in Bit [6:0].

1 = Enable USB device address.

0 = Disable USB device address.

**Bit [6:0]: Device Address Bit [6:0]**

These bits must be set by firmware during the USB enumeration process (i.e., SetAddress) to the non-zero address assigned by the USB host.

**USB Control Endpoint**

All USB devices are required to have an endpoint number 0 (EP0) that is used to initialize and control the USB device. EP0 provides access to the device configuration information and allows generic USB status and control accesses. EP0 is bidirectional as the device can both receive and transmit data. EP0 uses an 8-byte FIFO at SRAM locations 0xF8-0xFF, as shown in [Data Memory Organization on page 10](#).

The EP0 endpoint mode register uses the format shown in [Figure 16](#).

**Figure 16. Endpoint 0 Mode Register (Address 0x12)**

Bit #	7	6	5	4	3:0
Bit Name	SETUP Received	IN Received	OUT Received	ACKed Transaction	Mode Bit
Read/Write	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0 0 0 0

The SIE provides a locking feature to prevent firmware from overwriting bits in the USB Endpoint 0 Mode Register. Writes to the register have no effect from the point that Bit[6:0] of the register are updated (by the SIE) until the firmware reads this register. The CPU can unlock this register by reading it.

Because of these hardware-locking features, firmware should perform an read after a write to the USB Endpoint 0 Mode Register and USB Endpoint 0 Count Register ([Figure 18](#)) to

verify that the contents have changed as desired, and that the SIE has not updated these values.

Bit [7:4] of this register are cleared by any non-locked write to this register, regardless of the value written.

**Bit 7: SETUP Received**

1 = A valid SETUP packet has been received. This bit is forced HIGH from the start of the data packet phase of the SETUP transaction until the start of the ACK packet returned by the SIE. The CPU is prevented from clearing this bit during this interval. While this bit is set to '1', the CPU cannot write to the EP0 FIFO. This prevents firmware from overwriting an incoming SETUP transaction before firmware has a chance to read the SETUP data.

0 = No SETUP received. This bit is cleared by any non-locked writes to the register.

**Bit 6: IN Received**

1 = A valid IN packet has been received. This bit is updated to '1' after the last received packet in an IN transaction. This bit is cleared by any non-locked writes to the register.

0 = No IN received. This bit is cleared by any non-locked writes to the register.

**Bit 5: OUT Received**

1 = A valid OUT packet has been received. This bit is updated to '1' after the last received packet in an OUT transaction. This bit is cleared by any non-locked writes to the register.

0 = No OUT received. This bit is cleared by any non-locked writes to the register.

**Bit 4: ACKed Transaction**

The ACKed Transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with an ACK packet.

1 = The transaction completes with an ACK.

0 = The transaction does not complete with an ACK.

**Bit [3:0]: Mode Bit[3:0]**

The endpoint modes determine how the SIE responds to USB traffic that the host sends to the endpoint. For example, if the endpoint Mode Bits [3:0] are set to 0001 which is NAK IN/OUT mode as shown in [Table 8](#), the SIE will send NAK handshakes in response to any IN or OUT token sent to this endpoint. In this NAK IN/OUT mode, the SIE will send an ACK handshake when the host sends a SETUP token to this endpoint. The mode encoding is shown in [Table 8](#). Additional information on the mode bits can be found in [Table 9](#) and [Table 10](#). These modes give the firmware total control on how to respond to different tokens sent to the endpoints from the host.

In addition, the Mode Bits are automatically changed by the SIE in response to many USB transactions. For example, if the Mode Bit [3:0] are set to 1011 which is ACK OUT-NAK IN mode as shown in [Table 8](#), the SIE will change the endpoint Mode Bit [3:0] to NAK IN/OUT (0001) mode after issuing an ACK handshake in response to an OUT token. Firmware needs to update the mode for the SIE to respond appropriately.

## USB Non-control Endpoints

The CY7C637xxC feature two non-control endpoints, endpoint 1 (EP1) and endpoint 2 (EP2). The EP1 and EP2 Mode Registers do not have the locking mechanism of the EP0 Mode Register. The EP1 and EP2 Mode Registers use the format shown in [Figure 17](#). EP1 uses an 8-byte FIFO at SRAM locations 0xF0–0xF7, EP2 uses an 8-byte FIFO at SRAM locations 0xE8–0xEF as shown in [Data Memory Organization on page 10](#).

**Figure 17. USB Endpoint EP1, EP2 Mode Registers (Addresses 0x14 and 0x16)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	STALL	Reserved		ACKed Transaction	Mode Bit			
Read/Write	R/W	-	-	R/C	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

### Bit 7: STALL

1 = The SIE will stall an OUT packet if the Mode Bits are set to ACK-OUT, and the SIE will stall an IN packet if the mode bits are set to ACK-IN. See [USB Mode Tables on page 36](#) for the available modes.

0 = This bit must be set to LOW for all other modes.

**Bit [6:5]:** Reserved. Must be written to zero during register writes.

### Bit 4: ACKed Transaction

The ACKed transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with an ACK packet.

1 = The transaction completes with an ACK.

0 = The transaction does not complete with an ACK.

### Bit [3:0]: Mode Bit [3:0]

The EP1 and EP2 Mode Bits operate in the same manner as the EP0 Mode Bits (see [USB Mode Tables on page 36](#)).

## USB Endpoint Counter Registers

There are three Endpoint Counter registers, with identical formats for both control and non-control endpoints. These registers contain byte count information for USB transactions, as well as bits for data packet status. The format of these registers is shown in [Figure 18](#).

**Figure 18. Endpoint 0,1,2 Counter Registers (Addresses 0x11, 0x13 and 0x15)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Data Toggle	Data Valid	Reserved		Byte Count			
Read/Write	R/W	R/W	-	-	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

### Bit 7: Data Toggle

This bit selects the DATA packet's toggle state. For IN transactions, firmware must set this bit to the select the transmitted Data Toggle. For OUT or SETUP transactions, the hardware sets this bit to the state of the received Data Toggle bit.

1 = DATA1

0 = DATA0

### Bit 6: Data Valid

This bit is used for OUT and SETUP tokens only. This bit is cleared to '0' if CRC, bitstuff, or PID errors have occurred. This bit does not update for some endpoint mode settings. Refer to [Table 10](#) for more details.

1 = Data is valid.

0 = Data is invalid. If enabled, the endpoint interrupt will occur even if invalid data is received.

### Bit [5:4]: Reserved

### Bit [3:0]: Byte Count Bit [3:0]

Byte Count Bits indicate the number of data bytes in a transaction: For IN transactions, firmware loads the count with the number of bytes to be transmitted to the host from the endpoint FIFO. Valid values are 0 to 8 inclusive. For OUT or SETUP transactions, the count is updated by hardware to the number of data bytes received, plus 2 for the CRC bytes. Valid values are 2 to 10 inclusive.

For Endpoint 0 Count Register, whenever the count updates from a SETUP or OUT transaction, the count register locks and cannot be written by the CPU. Reading the register unlocks it. This prevents firmware from overwriting a status update on incoming SETUP or OUT transactions before firmware has a chance to read the data.

## USB Regulator Output

The VREG pin provides a regulated output for connecting the pull-up resistor required for USB operation. For USB, a 1.5-k $\Omega$  resistor is connected between the D<sup>-</sup> pin and the V<sub>REG</sub> voltage, to indicate low-speed USB operation. Since the VREG output has an internal series resistance of approximately 200 $\Omega$ , the external pull-up resistor required is R<sub>P<sub>U</sub></sub> (see [DC Characteristics on page 42](#)).

The regulator output is placed in a high-impedance state at reset, and must be enabled by firmware by setting the VREG Enable bit in the USB Status and Control Register ([Figure 14](#)). This simplifies the design of a combination PS/2-USB device, since the USB pull-up resistor can be left in place during PS/2 operation without loading the PS/2 line. In this mode, the V<sub>REG</sub> pin can be used as an input and its state can be read at port P2.0. Refer to [Figure 13 on page 19](#) for the Port 2 data register. This input has a TTL threshold.

In suspend mode, the regulator is automatically disabled. If VREG Enable bit is set ([Figure 14](#)), the VREG pin is pulled up to V<sub>CC</sub> with an internal 6.2-k $\Omega$  resistor. This holds the proper V<sub>OH</sub> state in suspend mode.

Note that enabling the device for USB (by setting the Device Address Enable bit, [Figure 15](#)) activates the internal regulator, even if the VREG Enable bit is cleared to 0. This insures proper

USB signaling in the case where the VREG pin is used as an input, and an external regulator is provided for the USB pull-up resistor. This also limits the swing on the D- and D+ pins to about 1V above the internal regulator voltage, so the Device Address Enable bit normally should only be set for USB operating modes.

The regulator output is only designed to provide current for the USB pull-up resistor. In addition, the output voltage at the VREG pin is effectively disconnected when the CY7C637xxC device transmits USB from the internal SIE. This means that the VREG pin does not provide a stable voltage during transmits, although this does not affect USB signaling.

## PS/2 Operation

The CY7C637xxC parts are optimized for combination USB or PS/2 devices, through the following features:

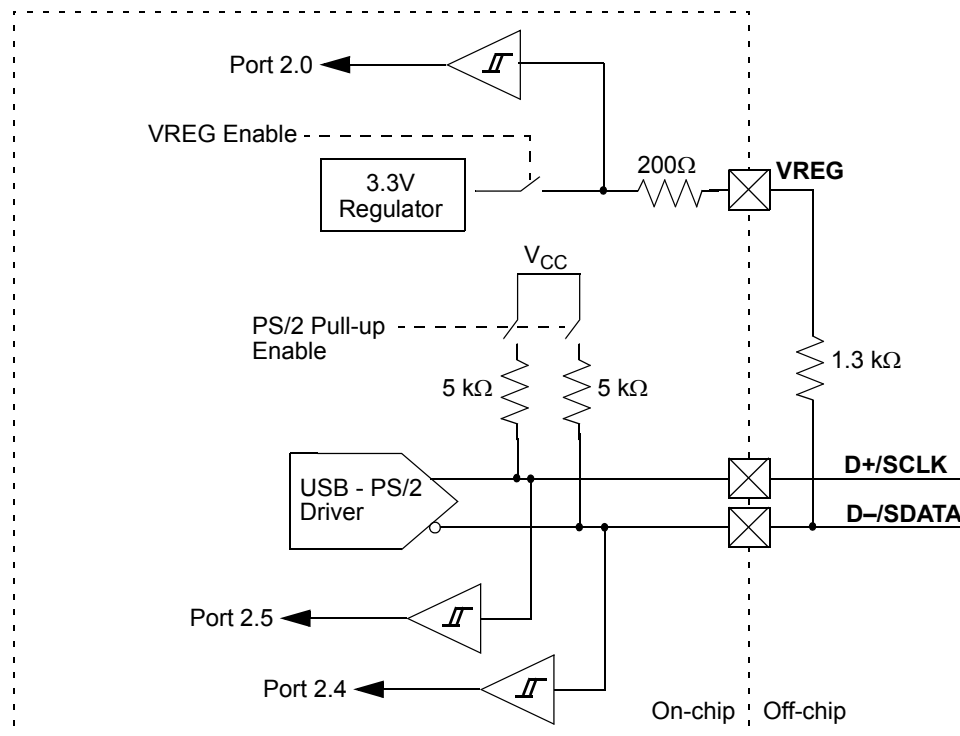

1. USB D+ and D- lines can also be used for PS/2 SCLK and SDATA pins, respectively. With USB disabled, these lines can be placed in a high-impedance state that will pull up to  $V_{CC}$ .

(Disable USB by clearing the Address Enable bit of the USB Device Address Register, [Figure 15](#)).

2. An interrupt is provided to indicate a long LOW state on the SDATA pin. This eliminates the need to poll this pin to check for PS/2 activity. Refer to [USB Port Status and Control](#) on [page 19](#) for more details.
3. Internal PS/2 pull-up resistors can be enabled on the SCLK and SDATA lines, so no GPIO pins are required for this task (bit 7, USB Status and Control Register, [Figure 14](#)).
4. The controlled slew rate outputs from these pins apply to both USB and PS/2 modes to minimize EMI.
5. The state of the SCLK and SDATA pins can be read, and can be individually driven LOW in an open drain mode. The pins are read at bits [5:4] of Port 2, and are driven with the Control Bits [2:0] of the USB Status and Control Register.
6. The  $V_{REG}$  pin can be placed into a high-impedance state, so that a USB pull-up resistor on the D-/SDATA pin will not interfere with PS/2 operation (bit 6, USB Status and Control Register).

The PS/2 on-chip support circuitry is illustrated in [Figure 19](#).

**Figure 19. Diagram of USB-PS/2 System Connections**

## Serial Peripheral Interface (SPI)

SPI is a four-wire, full-duplex serial communication interface between a master device and one or more slave devices. The CY7C637xxC SPI circuit supports byte serial transfers in either Master or Slave modes. The block diagram of the SPI circuit is shown in Figure 20. The block contains buffers for both transmit and receive data for maximum flexibility and throughput. The

CY7C637xxC can be configured as either an SPI Master or Slave. The external interface consists of Master-Out/Slave-In (MOSI), Master-In/Slave-Out (MISO), Serial Clock (SCK), and Slave Select ( $\overline{SS}$ ).

SPI modes are activated by setting the appropriate bits in the SPI Control Register, as described below.

**Figure 20. SPI Block Diagram**

The SPI Data Register below serves as a transmit and receive buffer.

**Figure 21. SPI Data Register (Address 0x60)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Data I/O							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

### Bit [7:0]: Data I/O[7:0]

Writes to the SPI Data Register load the transmit buffer, while reads from this register read the receive buffer contents.

1 = Logic HIGH

0 = Logic LOW

### Operation as an SPI Master

Only an SPI Master can initiate a byte/data transfer. This is done by the Master writing to the SPI Data Register. The Master shifts out 8 bits of data (MSB first) along with the serial clock SCK for the Slave. The Master's outgoing byte is replaced with an incoming one from a Slave device. When the last bit is received, the shift register contents are transferred to the receive buffer and an interrupt is generated. The receive data must be read

from the SPI Data Register before the next byte of data is transferred to the receive buffer, or the data will be lost.

When operating as a Master, an active LOW Slave Select ( $\overline{SS}$ ) must be generated to enable a Slave for a byte transfer. This Slave Select is generated under firmware control, and is not part of the SPI internal hardware. Any available GPIO can be used for the Master's Slave Select output.

When the Master writes to the SPI Data Register, the data is loaded into the transmit buffer. If the shift register is not busy shifting a previous byte, the TX buffer contents will be automatically transferred into the shift register and shifting will begin. If the shift register is busy, the new byte will be loaded into the shift register only after the active byte has finished and is transferred to the receive buffer. The new byte will then be shifted out. The Transmit Buffer Full (TBF) bit will be set HIGH until the transmit buffer's data-byte is transferred to the shift register. Writing to the transmit buffer while the TBF bit is HIGH will overwrite the old byte in the transmit buffer.

The byte shifting and SCK generation are handled by the hardware (based on firmware selection of the clock source). Data is shifted out on the MOSI pin (P0.5) and the serial clock SCK is output on the SCK pin (P0.7). Data is received from the slave on the MISO pin (P0.6). The output pins must be set to the desired drive strength, and the GPIO data register must be set to 1 to enable a bypass mode for these pins. The MISO pin must be configured in the desired GPIO input mode. See [General Purpose I/O Ports on page 17](#) for GPIO configuration details.

## Master SCK Selection

The Master's SCK is programmable to one of four clock settings, as shown in [Figure 20](#). The frequency is selected with the Clock Select Bits of the SPI control register. The hardware provides 8 output clocks on the SCK pin (P0.7) for each byte transfer. Clock phase and polarity are selected by the CPHA and CPOL control bits (see [Figure 20](#) and [Figure 23](#)).

The master SCK duty cycle is nominally 33% in the fastest (2 Mbps) mode, and 50% in all other modes.

## Operation as an SPI Slave

In slave mode, the chip receives SCK from an external master on pin P0.7. Data from the master is shifted in on the MOSI pin (P0.5), while data is being shifted out of the slave on the MISO pin (P0.6). In addition, the active LOW Slave Select must be asserted to enable the slave for transmit. The Slave Select pin is P0.4. These pins must be configured in appropriate GPIO modes, with the GPIO data register set to 1 to enable bypass mode selected for the MISO pin.

In Slave mode, writes to the SPI Data Register load the Transmit buffer. If the Slave Select is asserted (SS LOW) and the shift register is not busy shifting a previous byte, the transmit buffer contents will be automatically transferred into the shift register. If the shift register is busy, the new byte will be loaded into the shift register only after the active byte has finished and is transferred to the receive buffer. The new byte is then ready to be shifted out (shifting waits for SCK from the Master). If the Slave Select is not active when the transmit buffer is loaded, data is not transferred to the shift register until Slave Select is asserted. The Transmit Buffer Full (TBF) bit will be set to '1' until the transmit buffer's data-byte is transferred to the shift register. Writing to the transmit buffer while the TBF bit is HIGH will overwrite the old byte in the Transmit Buffer.

If the Slave Select is deasserted before a byte transfer is complete, the transfer is aborted and no interrupt is generated. Whenever Slave Select is asserted, the transmit buffer is automatically reloaded into the shift register.

Clock phase and polarity must be selected to match the SPI master, using the CPHA and CPOL control bits (see [Figure 22](#) and [Figure 23](#)).

The SPI slave logic continues to operate in suspend, so if the SPI interrupt is enabled, the device can go into suspend during a SPI slave transaction, and it will wake up at the interrupt that signals the end of the byte transfer.

## SPI Status and Control

The SPI Control Register is shown in [Figure 22](#). The timing diagram in [Figure 23](#) shows the clock and data states for the various SPI modes.

**Figure 22. SPI Control Register (Address 0x61)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	TCMP	TBF	Comm Mode[1:0]		CPOL	CPHA	SCK Select	
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

### Bit 7: TCMP

1 = TCMP is set to 1 by the hardware when 8-bit transfer is complete. The SPI interrupt is asserted at the same time TCMP is set to 1.

0 = This bit is only cleared by firmware.

### Bit 6: TBF

Transmit Buffer Full bit.

1 = Indicates data in the transmit buffer has not transferred to the shift register.

0 = Indicates data in the transmit buffer has transferred to the shift register.

### Bit [5:4] Comm Mode[1:0]

00 = All communications functions disabled (default).

01 = SPI Master Mode.

10 = SPI Slave Mode.

11 = Reserved.

### Bit 3: CPOL

SPI Clock Polarity bit.

1 = SCK idles HIGH.

0 = SCK idles LOW.

### Bit 2: CPHA

SPI Clock Phase bit (see [Figure 23](#))

### Bit [1:0]: SCK Select

Master mode SCK frequency selection (no effect in Slave Mode):

00 = 2 Mbit/s

01 = 1 Mbit/s

10 = 0.5 Mbit/s

11 = 0.0625 Mbit/s

**Figure 23. SPI Data Timing**

### SPI Interrupt

For SPI, an interrupt request is generated after a byte is received or transmitted. See [Interrupt Sources on page 32](#) for details on the SPI interrupt.

### SPI Modes for GPIO Pins

The GPIO pins used for SPI outputs (P0.5–P0.7) contain a bypass mode, as shown in the GPIO block diagram ([Figure 6 on page 17](#)). Whenever the SPI block is inactive (Mode[5:4] = 00), the bypass value is 1, which enables normal GPIO operation.

When SPI master or slave modes are activated, the appropriate bypass signals are driven by the hardware for outputs, and are held at 1 for inputs. **Note that the corresponding data bits in the Port 0 Data Register must be set to 1 for each pin being used for an SPI output.** In addition, the GPIO modes are not affected by operation of the SPI block, so each pin must be programmed by firmware to the desired drive strength mode.

For GPIO pins that are not used for SPI outputs, the SPI bypass value in [Figure 6 on page 17](#) is always 1, for normal GPIO operation.

**Table 5. SPI Pin Assignments**

SPI Function	GPIO Pin	Comment
Slave Select ( $\overline{SS}$ )	P0.4	For master mode, firmware sets $\overline{SS}$ , may use any GPIO pin. For Slave Mode, $\overline{SS}$ is an active LOW input.
Master Out, Slave In (MOSI)	P0.5	Data output for master, data input for slave.
Master In, Slave Out (MISO)	P0.6	Data input for master, data output for slave.
SCK	P0.7	SPI Clock: Output for master, input for slave.

## 12-bit Free-running Timer

The 12-bit timer operates with a 1- $\mu$ s tick, provides two interrupts (128- $\mu$ s and 1.024-ms) and allows the firmware to directly time events that are up to 4 ms in duration. The lower eight bits of the timer can be read directly by the firmware. Reading the lower eight bits latches the upper four bits into a temporary register. When the firmware reads the upper four bits of the timer, it is actually reading the count stored in the temporary register. The effect of this is to ensure a stable 12-bit timer value can be read, even when the two reads are separated in time.

**Figure 24. Timer LSB Register (Address 0x24)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Timer [7:0]

**Bit [7:4]:** Reserved

**Bit [3:0]:** Timer upper four bits

**Figure 26. Timer Block Diagram**

## Timer Capture Registers

Four 8-bit capture timer registers provide both rising- and falling-edge event timing capture on two pins. Capture Timer A is connected to Pin 0.0, and Capture Timer B is connected to Pin 0.1. These can be used to mark the time at which a rising or falling event occurs at the two GPIO pins. Each timer will capture eight bits of the free-running timer into its Capture Timer Data Register if a rising or falling edge event that matches the specified rising or falling edge condition at the pin. A prescaler allows selection of the capture timer tick size. Interrupts can be individually enabled for the four capture registers. A block diagram is shown in [Figure 27](#).

**Figure 27. Capture Timers Block Diagram**

The four Capture Timer Data Registers are read-only, and are shown in [Figure 28](#) through [Figure 31](#).

Out of the 12-bit free running timer, the 8-bit captured in the Capture Timer Data Registers are determined by the Prescale Bit [2:0] in the Capture Timer Configuration Register ([Figure 33](#)).

**Figure 28. Capture Timer A-Rising, Data Register (Address 0x40)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Capture A Rising Data							
Read/Write	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

**Figure 29. Capture Timer A-Falling, Data Register (Address 0x41)**

Bit #	7	6	5	4	3	2	1	0

**Figure 31. Capture Timer B-Falling, Data Register (Address 0x43)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Capture B Falling Data							
Read/Write	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

**Figure 32. Capture Timer Status Register (Address 0x45)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Reserved				Capture B Falling Event	Capture B Rising Event	Capture A Falling Event	Capture A Rising Event
Read/Write	-	-	-	-	R	R	R	R

Reset	0	0	0	0	0	0	0	0
-------	---	---	---	---	---	---	---	---

**Bit [7:4]:** Reserved.

**Bit [3:0]: Capture A/B, Falling/Rising Event**

These bits record the occurrence of any rising or falling edges on the capture GPIO pins. Bits in this register are cleared by reading the corresponding data register.

1 = A rising or falling event that matches the pin's rising/falling condition has occurred.

0 = No event that matches the pin's rising or falling edge condition.

Because both Capture A events (rising and falling) share an interrupt, user's firmware needs to check the status of both Capture A Falling and Rising Event bits to determine what caused the interrupt. This is also true for Capture B events.

**Figure 33. Capture Timer Configuration Register (Address 0x44)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	First Edge Hold	Prescale Bit [2:0]			Capture B Falling Int Enable	Capture B Rising Int Enable	Capture A Falling Int Enable	Capture A Rising Int Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

**Bit 7: First Edge Hold**

1 = The time of the first occurrence of an edge is held in the Capture Timer Data Register until the data is read. Subsequent edges are ignored until the Capture Timer Data Register is read.

0 = The time of the most recent edge is held in the Capture Timer Data Register. That is, if multiple edges have occurred before reading the capture timer, the time for the last one will be read (default state).

The First Edge Hold function applies globally to all four capture timers.

**Bit [6:4]: Prescale Bit [2:0]**

Three prescaler bits allow the capture timer clock rate to be selected among 5 choices, as shown in [Table 6](#) below.

**Bit [3:0]: Capture A/B, Rising/Falling Interrupt Enable**

Each of the four Capture Timer registers can be individually enabled to provide interrupts.

Both Capture A events share a common interrupt request, as do the two Capture B events. In addition to the event enables, the main Capture Interrupt Enables bit in the Global Interrupt Enable register ([Interrupt Sources on page 32](#)) must be set to activate a capture interrupt.

1 = Enable interrupt

0 = Disable interrupt

**Table 6. Capture Timer Prescaler Settings (Step size and range for  $F_{CLK} = 6$  MHz)**

Prescale 2:0	Captured Bits	LSB Step Size	Range
000	Bits 7:0 of free-running timer	1 $\mu$ s	256 $\mu$ s
001	Bits 8:1 of free-running timer	2 $\mu$ s	512 $\mu$ s
010	Bits 9:2 of free-running timer	4 $\mu$ s	1.024 ms
011	Bits 10:3 of free-running timer	8 $\mu$ s	2.048 ms

**Table 6. Capture Timer Prescaler Settings (Step size and range for  $F_{CLK} = 6$  MHz)**

100	Bits 11:4 of free-running timer	16 $\mu$ s	4.096 ms
-----	---------------------------------	------------	----------

## Processor Status and Control Register

**Figure 34. Processor Status and Control Register (Address 0xFF)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	IRQ Pending	Watchdog Reset	Bus Interrupt Event	LVR/BOR Reset	Suspend	Interrupt Enable Sense	Reserved	Run
Read/Write	R	R/W	R/W	R/W	R/W	R	-	R/W
Reset	0	1	0	1	0	0	0	1

### Bit 7: IRQ Pending

When an interrupt is generated, it is registered as a pending interrupt. The interrupt will remain pending until its interrupt enable bit is set (Figure 35 and Figure 36) and interrupts are globally enabled (Bit 2, Processor Status and Control Register). At that point the internal interrupt handling sequence will clear the IRQ Pending bit until another interrupt is detected as pending. This bit is only valid if the Global Interrupt Enable bit is disabled.

- 1 = There are pending interrupts.
- 0 = No pending interrupts.

### Bit 6: Watchdog Reset

The Watchdog Timer Reset (WDR) occurs when the internal Watchdog timer rolls over. The timer will roll over and WDR will occur if it is not cleared within  $t_{WATCH}$  (see [Switching Characteristics on page 44](#) for the value of  $t_{WATCH}$ ). This bit is cleared by an LVR/BOR. Note that a Watchdog reset can occur with a POR/LVR/BOR event, as discussed at the end of this section.

- 1 = A Watchdog reset occurs.
- 0 = No Watchdog reset

### Bit 5: Bus Interrupt Event

The Bus Reset Status is set whenever the event for the USB Bus Reset or PS/2 Activity interrupt occurs. The event type (USB or PS/2) is selected by the state of the USB-PS/2 Interrupt Mode bit in the USB Status and Control Register (see [Figure 14](#)). The details on the event conditions that set this bit are given in [Interrupt Sources on page 32](#). In either mode, this bit is set as soon as the event has lasted for 128–256  $\mu$ s, and

the bit will be set even if the interrupt is not enabled. The bit is only cleared by firmware or LVR/WDR.

1 = A USB reset occurred or PS/2 Activity is detected, depending on USB-PS/2 Interrupt Select bit.

0 = No event detected since last cleared by firmware or LVR/WDR.

### Bit 4: LVR/BOR Reset

The Low-voltage or Brown-out Reset is set to '1' during a power-on reset. Firmware can check bits 4 and 6 in the reset handler to determine whether a reset was caused by a LVR/BOR condition or a Watchdog timeout. This bit is not affected by WDR. Note that a LVR/BOR event may be followed by a Watchdog reset before firmware begins executing, as explained at the end of this section.

- 1 = A POR or LVR has occurred.
- 0 = No POR nor LVR since this bit last cleared.

### Bit 3: Suspend

Writing a '1' to the Suspend bit will halt the processor and cause the microcontroller to enter the suspend mode that significantly reduces power consumption. An interrupt or USB bus activity will cause the device to come out of suspend. After coming out of suspend, the device will resume firmware execution at the instruction following the IOWR which put the part into suspend. When writing the suspend bit with a resume condition present (such as non-idle USB activity), the suspend state will still be entered, followed immediately by the wake-up process (with appropriate delays for the clock start-up). See [Suspend Mode on page 15](#) for more details on suspend mode operation.

1 = Suspend the processor.

0 = Not in suspend mode. Cleared by the hardware when resuming from suspend.

#### Bit 2: Interrupt Enable Sense

This bit shows whether interrupts are enabled or disabled. Firmware has no direct control over this bit as writing a zero or one to this bit position will have no effect on interrupts. This bit is further gated with the bit settings of the Global Interrupt Enable Register (Figure 35) and USB Endpoint Interrupt Enable Register (Figure 36). Instructions DI, EI, and RETI manipulate the state of this bit.

1 = Interrupts are enabled.

0 = Interrupts are masked off.

**Bit 1:** Reserved. Must be written as a 0.

#### Bit 0: Run

This bit is manipulated by the HALT instruction. When Halt is executed, the processor clears the run bit and halts at the end of the current instruction. The processor remains halted until a reset occurs (low-voltage, brown-out, or Watchdog). This bit should normally be written as a '1'.

During power-up, or during a low-voltage reset, the Processor Status and Control Register is set to 00010001, which indicates a LVR/BOR (bit 4 set) has occurred and no interrupts are pending (bit 7 clear). Note that during the  $t_{\text{START}}$  ms partial suspend at start-up (explained in Reset on page 13), a Watchdog Reset will also occur. When a WDR occurs during the power-up suspend interval, firmware would read 01010001 from the Status and Control Register after power-up. Normally the LVR/BOR bit should be cleared so that a subsequent WDR can be clearly identified. *Note that if a USB bus reset (long SE0) is received before firmware examines this register, the Bus Interrupt Event bit would also be set.*

During a Watchdog Reset, the Processor Status and Control Register is set to 01XX0001, which indicates a Watchdog Reset (bit 4 set) has occurred and no interrupts are pending (bit 7 clear).

## Interrupts

Interrupts can be generated by the GPIO lines, the internal free-running timer, the SPI block, the capture timers, on various USB events, PS/2 activity, or by the wake-up timer. All interrupts are maskable by the Global Interrupt Enable Register and the USB End Point Interrupt Enable Register. Writing a '1' to a bit position enables the interrupt associated with that bit position. During a reset, the contents of the interrupt enable registers are cleared, along with the Global Interrupt enable bit of the CPU, effectively disabling all interrupts.

The interrupt controller contains a separate flip-flop for each interrupt. See Figure 37 for the logic block diagram of the interrupt controller. When an interrupt is generated it is first registered as a pending interrupt. It will stay pending until it is serviced or a reset occurs. A pending interrupt will only generate an interrupt request if it is enabled by the corresponding bit in the interrupt enable registers. The highest priority interrupt request will be serviced following the completion of the currently executing instruction.

When servicing an interrupt, the hardware will first disable all interrupts by clearing the Global Interrupt Enable bit in the CPU (the state of this bit can be read at Bit 2 of the Processor Status and Control Register). Next, the flip-flop of the current interrupt is cleared. This is followed by an automatic CALL instruction to the ROM address associated with the interrupt being serviced (i.e., the Interrupt Vector, see [Interrupt Vectors on page 31](#)). The instruction in the interrupt table is typically a JMP instruction to the address of the Interrupt Service Routine (ISR). The user can re-enable interrupts in the interrupt service routine by executing an EI instruction. Interrupts can be nested to a level limited only by the available stack space.

The Program Counter value as well as the Carry and Zero flags (CF, ZF) are stored onto the Program Stack by the automatic CALL instruction generated as part of the interrupt acknowledge process. The user firmware is responsible for ensuring that the processor state is preserved and restored during an interrupt. The PUSH A instruction should typically be used as the first command in the ISR to save the accumulator value and the POP A instruction should be used just before the RETI instruction to restore the accumulator value. The program counter, CF and ZF are restored and interrupts are enabled when the RETI instruction is executed.

The DI and EI instructions can be used to disable and enable interrupts, respectively. These instructions affect only the Global Interrupt Enable bit of the CPU. If desired, EI can be used to re-enable interrupts while inside an ISR, instead of waiting for the RETI that exits the ISR. While the global interrupt enable bit is cleared, the presence of a pending interrupt can be detected by examining the IRQ Sense bit (Bit 7 in the Processor Status and Control Register).

## Interrupt Vectors

The Interrupt Vectors supported by the device are listed in Table 7. The highest priority interrupt is #1 (USB Bus Reset / PS/2 activity), and the lowest priority interrupt is #11 (Wake-up Timer). Although Reset is not an interrupt, the first instruction executed after a reset is at ROM address 0x0000, which corresponds to the first entry in the Interrupt Vector Table. Interrupt vectors occupy two bytes to allow for a two-byte JMP instruction to the appropriate Interrupt Service Routine (ISR).

**Table 7. Interrupt Vector Assignments**

Interrupt Vector No.	ROM Address	Function
not applicable	0x0000	Execution after Reset begins here
1	0x0002	USB Bus Reset or PS/2 Activity interrupt
2	0x0004	128- $\mu$ s timer interrupt
3	0x0006	1.024-ms timer interrupt
4	0x0008	USB Endpoint 0 interrupt
5	0x000A	USB Endpoint 1 interrupt
6	0x000C	USB Endpoint 2 interrupt
7	0x000E	SPI Interrupt
8	0x0010	Capture Timer A interrupt

**Table 7. Interrupt Vector Assignments**

9	0x0012	Capture Timer B interrupt
10	0x0014	GPIO interrupt
11	0x0016	Wake-up Timer interrupt

### Interrupt Latency

Interrupt latency can be calculated from the following equation:

$$\begin{aligned} \text{Interrupt Latency} = & \text{(Number of clock cycles remaining in the} \\ & \text{current instruction)} \\ & + \text{(10 clock cycles for the CALL instruction)} \\ & + \text{(5 clock cycles for the JMP instruction)} \end{aligned}$$

For example, if a 5 clock cycle instruction such as JC is being executed when an interrupt occurs, the first instruction of the Interrupt Service Routine will execute a minimum of 16 clocks (1+10+5) or a maximum of 20 clocks (5+10+5) after the interrupt is issued. With a 6-MHz external resonator, internal CPU clock speed is 12 MHz, so 20 clocks take  $20/12 \text{ MHz} = 1.67 \mu\text{s}$ .

### Interrupt Sources

The following sections provide details on the different types of interrupt sources.

**Figure 35. Global Interrupt Enable Register (Address 0x20)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Wake-up Interrupt Enable	GPIO Interrupt Enable	Capture Timer B Intr. Enable	Capture Timer A Intr. Enable	SPI Interrupt Enable	1.024-ms Interrupt Enable	128-μs Interrupt Enable	USB Bus Reset / PS/2 Activity Intr. Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

#### Bit 7: Wake-up Interrupt Enable

The internal wake-up timer is normally used to wake the part from suspend mode, but it can also provide an interrupt when the part is awake. The wake-up timer is cleared whenever the Wake-up Interrupt Enable bit is written to a 0, and runs whenever that bit is written to a 1. When the interrupt is enabled, the wake-up timer provides periodic interrupts at multiples of period, as described in [Wake-up Timer on page 16](#).

1 = Enable wake-up timer for periodic wake-up.

0 = Disable and power-off wake-up timer.

#### Bit 6: GPIO Interrupt Enable

Each GPIO pin can serve as an interrupt input. During a reset, GPIO interrupts are disabled by clearing all GPIO interrupt enable registers. Writing a '1' to a GPIO Interrupt Enable bit enables GPIO interrupts from the corresponding input pin. These registers are shown in [Figure 38](#) for Port 0 and [Figure 39](#) for Port 1. In addition to enabling the desired individual pins for interrupt, the main GPIO interrupt must be enabled, as explained in [General Purpose I/O Ports on page 17](#).

The polarity that triggers an interrupt is controlled independently for each GPIO pin by the GPIO Interrupt Polarity Registers. Setting a Polarity bit to '0' allows an interrupt on a falling GPIO edge, while setting a Polarity bit to '1' allows an interrupt on a rising GPIO edge. The Polarity Registers reset to 0 and are shown in [Figure 38](#) for Port 0 and [Figure 40](#) for Port 1.

All of the GPIO pins share a single interrupt vector, which means the firmware will need to read the GPIO ports with enabled interrupts to determine which pin or pins caused an interrupt. The GPIO interrupt structure is illustrated in [Figure 41](#).

Note that if one port pin triggered an interrupt, no other port pins can cause a GPIO interrupt until that port pin has returned to its inactive (non-trigger) state or its corresponding port interrupt enable bit is cleared. The CY7C637xxC does not assign interrupt priority to different port pins and the Port Interrupt Enable Registers are not affected by the interrupt acknowledge process.

1 = Enable

0 = Disable

#### Bit [5:4]: Capture Timer A and B Interrupts

There are two capture timer interrupts, one for each associated pin. Each of these interrupts occurs on an enabled edge of the selected GPIO pin(s). For each pin, rising and/or falling edge capture interrupts can be in selected. Refer to [Timer Capture Registers on page 28](#). These interrupts are independent of the GPIO interrupt, described in the next section.

1 = Enable

0 = Disable

#### Bit 3: SPI Interrupt Enable

The SPI interrupt occurs at the end of each SPI byte transaction, at the final clock edge, as shown in [Figure 23](#). After the interrupt, the received data byte can be read from the SPI Data Register, and the TCMP control bit will be high

1 = Enable

0 = Disable

#### Bit 2: 1.024-ms Interrupt Enable

The 1.024-ms interrupts are periodic timer interrupts from the free-running timer (based on the 6-MHz clock). The user should disable this interrupt before going into the suspend

mode to avoid possible conflicts between servicing the timer interrupts (128- $\mu$ s interrupt and 1.024-ms interrupt) first or the suspend request first when waking up.

1 = Enable. Periodic interrupts will be generated approximately every 1.024 ms.

0 = Disable.

#### Bit 1: 128- $\mu$ s Interrupt Enable

The 128- $\mu$ s interrupt is another source of timer interrupt from the free-running timer. The user should disable both timer interrupts (128- $\mu$ s and 1.024-ms) before going into the suspend mode to avoid possible conflicts between servicing the timer interrupts first or the suspend request first when waking up.

1 = Enable. Periodic interrupts will be generated approximately every 128  $\mu$ s.

0 = Disable.

#### Bit 0: USB Bus Reset - PS/2 Interrupt Enable

The function of this interrupt is selectable between detection of either a USB bus reset condition, or PS/2 activity. The selection is made with the USB-PS/2 Interrupt Mode bit in the USB Status and Control Register (Figure 14). In either case, the interrupt will occur if the selected condition exists for 256  $\mu$ s, and may occur as early as 128  $\mu$ s.

A USB bus reset is indicated by a single ended zero (SE0) on the USB D+ and D- pins. The USB Bus Reset interrupt occurs when the SE0 condition ends. PS/2 activity is indicated by a continuous LOW on the SDATA pin. The PS/2 interrupt occurs as soon as the long LOW state is detected.

During the entire interval of a USB Bus Reset or PS/2 interrupt event, the USB Device Address register is cleared.

The Bus Reset/PS/2 interrupt may occur 128  $\mu$ s after the bus condition is removed.

1 = Enable

0 = Disable

**Figure 36. Endpoint Interrupt Enable Register (Address 0x21)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	Reserved					EP2 Interrupt Enable	EP1 Interrupt Enable	EP0 Interrupt Enable

Read/Write	-	-	-	-	-	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

**Bit [7:3]: Reserved.**

#### Bit [2:1]: EP2,1 Interrupt Enable

There are two non-control endpoint (EP2 and EP1) interrupts. If enabled, a non-control endpoint interrupt is generated when:

- ❑ The USB host writes valid data to an endpoint FIFO. However, if the endpoint is in ACK OUT modes, an interrupt is generated regardless of data packet validity (i.e., good CRC). Firmware must check for data validity.
- ❑ The device SIE sends a NAK or STALL handshake packet to the USB host during the host attempts to read data from the endpoint (INs).
- ❑ The device receives an ACK handshake after a successful read transaction (IN) from the host.
- ❑ The device SIE sends a NAK or STALL handshake packet to the USB host during the host attempts to write data (OUTs) to the endpoint FIFO.

1 = Enable

0 = Disable

Refer to Table 8 for more information.

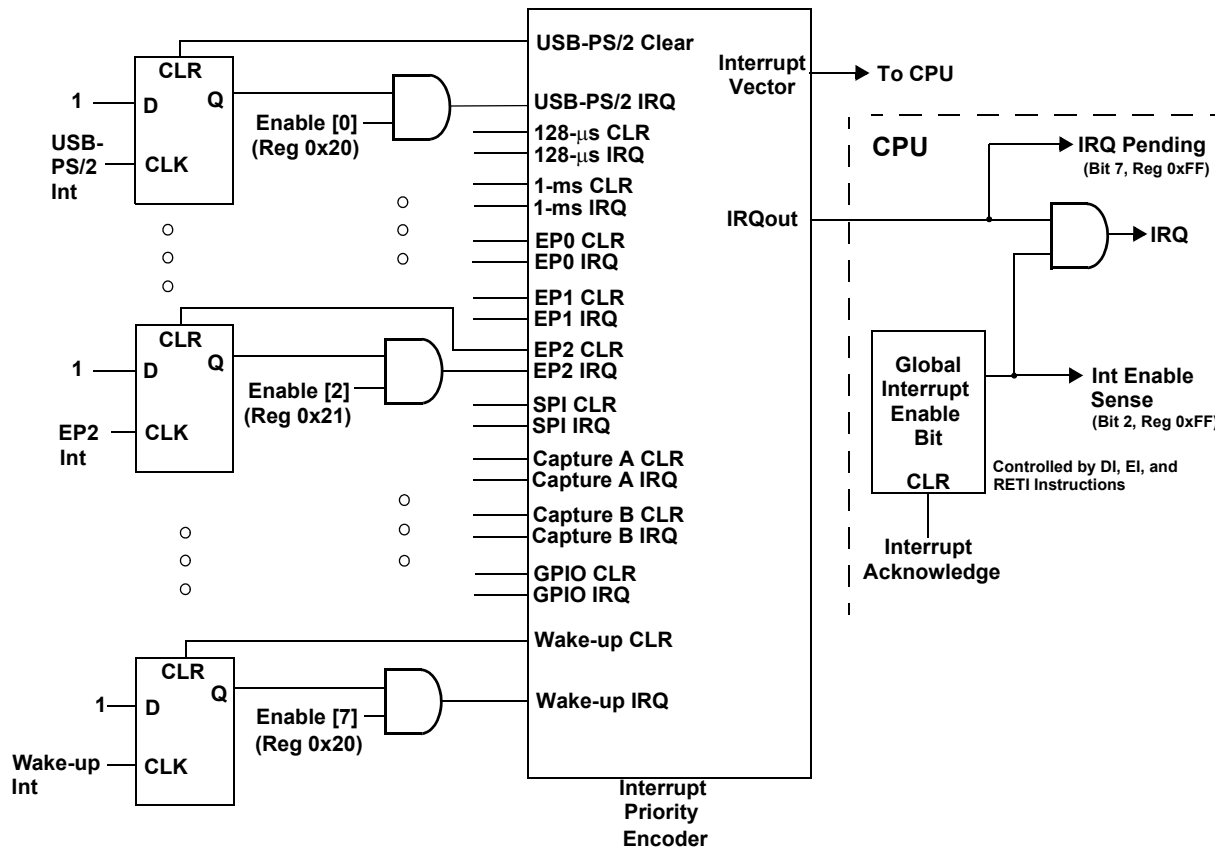

#### Bit 0: EP0 Interrupt Enable

If enabled, a control endpoint interrupt is generated when:

- ❑ The endpoint 0 mode is set to accept a SETUP token.
- ❑ After the SIE sends a 0-byte packet in the status stage of a control transfer.
- ❑ The USB host writes valid data to an endpoint FIFO. However, if the endpoint is in ACK OUT modes, an interrupt is generated regardless of what data is received. Firmware must check for data validity.
- ❑ The device SIE sends a NAK or STALL handshake packet to the USB host during the host attempts to read data from the endpoint (INs).
- ❑ The device SIE sends a NAK or STALL handshake packet to the USB host during the host attempts to write data (OUTs) to the endpoint FIFO.

1 = Enable EP0 interrupt

0 = Disable EP0 interrupt

**Figure 37. Interrupt Controller Logic Block Diagram**

**Figure 38. Port 0 Interrupt Enable Register (Address 0x04)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	P0 Interrupt Enable							
Read/Write	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

**Bit [7:0]: P0 [7:0] Interrupt Enable**

1 = Enables GPIO interrupts from the corresponding input pin.  
 0 = Disables GPIO interrupts from the corresponding input pin.

**Figure 39. Port 1 Interrupt Enable Register (Address 0x05)**

Bit #	7	6	5	4	3	2	1	0
Bit Name	P1 Interrupt Enable							
Read/Write	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

**Bit [7:0]: P1 [7:0] Interrupt Enable**

1 = Enables GPIO interrupts from the corresponding input pin.  
 0 = Disables GPIO interrupts from the corresponding input pin.

The polarity that triggers an interrupt is controlled independently for each GPIO pin by the GPIO Interrupt Polarity Registers. [Figure 38](#) and [Figure 40](#) control the interrupt polarity of each GPIO pin.

**Port 0 Interrupt Polarity Register (Address 0x06)**

0 = Falling GPIO edge

**Figure 41. GPIO Interrupt Diagram**

## USB Mode Tables

The following tables give details on mode setting for the USB Serial Interface Engine (SIE) for both the control endpoint (EP0) and non-control endpoints (EP1 and EP2).

**Table 8. USB Register Mode Encoding for Control and Non-Control Endpoints**

Mode	Encoding	SETUP	IN	OUT	Comments
Disable	0000	Ignore	Ignore	Ignore	Ignore all USB traffic to this endpoint
NAK IN/OUT	0001	Accept	NAK	NAK	On Control endpoint, after successfully sending an ACK handshake to a SETUP packet, the SIE forces the endpoint mode (from modes other than 0000) to 0001. The mode is also changed by the SIE to 0001 from mode 1011 on issuance of ACK handshake to an OUT.
Status OUT Only	0010	Accept	STALL	Check	For Control endpoints
STALL IN/OUT	0011	Accept	STALL	STALL	For Control endpoints
Ignore IN/OUT	0100	Accept	Ignore	Ignore	For Control endpoints
Reserved	0101	Ignore	Ignore	Always	Reserved
Status IN Only	0110	Accept	TX 0 Byte	STALL	For Control Endpoints
Reserved	0111	Ignore	TX Count	Ignore	Reserved
NAK OUT	1000	Ignore	Ignore	NAK	In mode 1001, after sending an ACK handshake to an OUT, the SIE changes the mode to 1000
ACK OUT(STALL <sup>[4]</sup> =0)	1001	Ignore	Ignore	ACK	This mode is changed by the SIE to mode 1000 on issuance of ACK handshake to an OUT
ACK OUT(STALL <sup>[4]</sup> =1)	1001	Ignore	Ignore	STALL	
NAK OUT - Status IN	1010	Accept	TX 0 Byte	NAK	
ACK OUT - NAK IN	1011	Accept	NAK	ACK	This mode is changed by the SIE to mode 0001 on issuance of ACK handshake to an OUT
NAK IN	1100	Ignore	NAK	Ignore	An ACK from mode 1101 changes the mode to 1100
ACK IN(STALL <sup>[4]</sup> =0)	1101	Ignore	TX Count	Ignore	This mode is changed by the SIE to mode 1100 on issuance of ACK handshake to an IN
ACK IN(STALL <sup>[4]</sup> =1)	1101	Ignore	STALL	Ignore	
NAK IN - Status OUT	1110	Accept	NAK	Check	An ACK from mode 1111 changes the mode to 1110
ACK IN - Status OUT	1111	Accept	TX Count	Check	This mode is changed by the SIE to mode 1110 on issuance of ACK handshake to an IN

**Note**

4. STALL bit is the bit 7 of the USB Non-Control Device Endpoint Mode registers. Refer to [USB Non-control Endpoints on page 22](#) for more explanation.

### Mode Column:

The 'Mode' column contains the mnemonic names given to the modes of the endpoint. The mode of the endpoint is determined by the four-bit binaries in the 'Encoding' column as discussed below. The Status IN and Status OUT modes represent the status IN or OUT stage of the control transfer.

### Encoding Column:

The contents of the 'Encoding' column represent the Mode Bits [3:0] of the Endpoint Mode Registers ([Figure 16](#) and [Figure 17](#)). The endpoint modes determine how the SIE responds to different tokens that the host sends to the endpoints. For example, if the Mode Bits [3:0] of the Endpoint 0 Mode Register ([Figure 16](#)) are set to '0001', which is NAK IN/OUT mode as shown in [Table 8](#) above, the SIE of the part will send an ACK handshake in response to SETUP tokens and NAK any IN or OUT tokens. For more information on the functionality of the Serial Interface Engine (SIE), see [USB Serial Interface Engine \(SIE\) on page 19](#).

### SETUP, IN, and OUT Columns:

Depending on the mode specified in the 'Encoding' column, the 'SETUP', 'IN', and 'OUT' columns contain the device SIE's

responses when the endpoint receives SETUP, IN, and OUT tokens respectively.

A 'Check' in the Out column means that upon receiving an OUT token the SIE checks to see whether the OUT is of zero length and has a Data Toggle (Data1/0) of 1. If these conditions are true, the SIE responds with an ACK. If any of the above conditions is not met, the SIE will respond with either a STALL or Ignore. [Table 10](#) gives a detailed analysis of all possible cases.

A 'TX Count' entry in the IN column means that the SIE will transmit the number of bytes specified in the Byte Count Bit [3:0] of the Endpoint Count Register ([Figure 18](#)) in response to any IN token.

A 'TX 0 Byte' entry in the IN column means that the SIE will transmit a zero byte packet in response to any IN sent to the endpoint. Sending a 0 byte packet is to complete the status stage of a control transfer.

An 'Ignore' means that the device sends no handshake tokens.

An 'Accept' means that the SIE will respond with an ACK to a valid SETUP transaction.

### Comments Column:

Some Mode Bits are automatically changed by the SIE in response to many USB transactions. For example, if the Mode

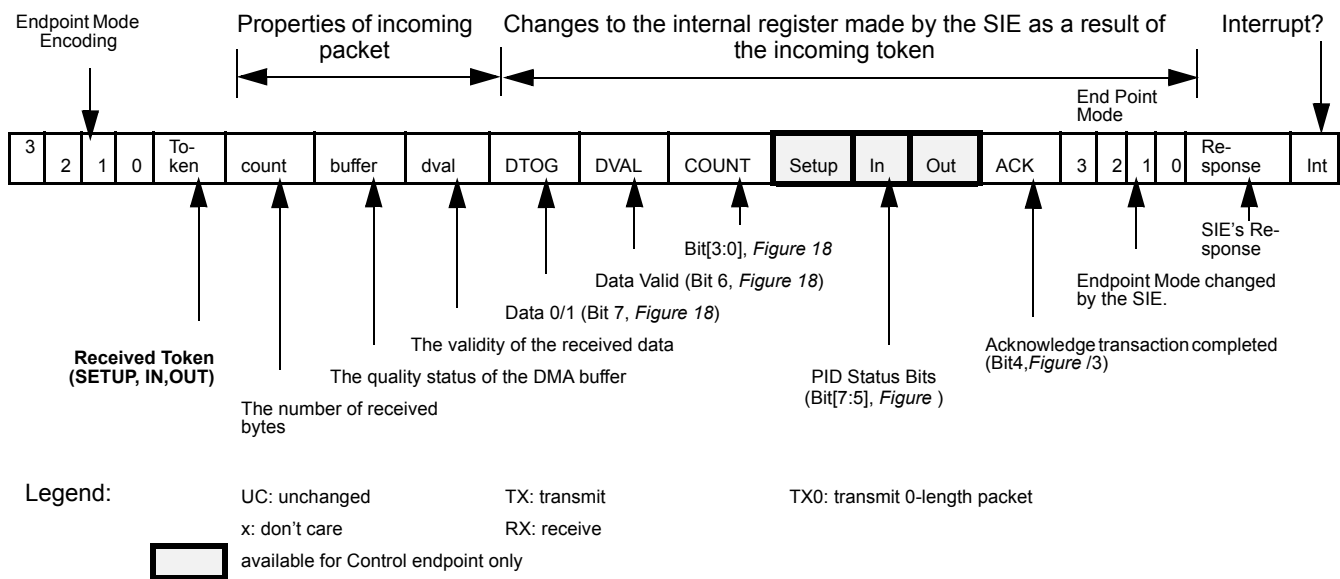

Bits [3:0] are set to '1111' which is ACK IN-Status OUT mode as shown in Table 8, the SIE will change the endpoint Mode Bits [3:0] to NAK IN-Status OUT mode (1110) after ACKing a valid status stage OUT token. The firmware needs to update the mode for the SIE to respond appropriately. See Table 8 for more details on what modes will be changed by the SIE.

Any SETUP packet to an enabled endpoint with mode set to accept SETUPS will be changed by the SIE to 0001 (NAKING). Any mode set to accept a SETUP will send an ACK handshake to a valid SETUP token.

A disabled endpoint will remain disabled until changed by firmware, and all endpoints reset to the Disabled mode (0000). Firmware normally enables the endpoint mode after a SetConfiguration request.

The control endpoint has three status bits for identifying the token type received (SETUP, IN, or OUT), but the endpoint must be placed in the correct mode to function as such. Non-control endpoints should not be placed into modes that accept SETUPS.

**Table 9. Decode table for Table 10: “Details of Modes for Differing Traffic Conditions”**

The response of the SIE can be summarized as follows:

1. The SIE will only respond to valid transactions, and will ignore non-valid ones.
2. The SIE will generate an interrupt when a valid transaction is completed or when the FIFO is corrupted. FIFO corruption occurs during an OUT or SETUP transaction to a valid internal address, that ends with a non-valid CRC.
3. An incoming Data packet is valid if the count is  $\leq$  Endpoint Size + 2 (includes CRC) and passes all error checking;
4. An IN will be ignored by an OUT configured endpoint and visa versa.
5. The IN and OUT PID status is updated at the end of a transaction.
6. The SETUP PID status is updated at the beginning of the Data packet phase.
7. The entire Endpoint 0 mode register and the Count register are locked to CPU writes at the end of any transaction to that endpoint in which an ACK is transferred. These registers are only unlocked by a CPU read of these registers, and only if that read happens after the transaction completes. This represents about a 1- $\mu$ s window in which the CPU is locked from register writes to these USB registers. Normally the firmware should perform a register read at the beginning of the Endpoint ISRs to unlock and get the mode register information. The interlock on the Mode and Count registers ensures that the firmware recognizes the changes that the SIE might have made during the previous transaction.

**Table 10. Details of Modes for Differing Traffic Conditions**

End Point Mode											PID				Set End Point Mode						
3	2	1	0	Rcvd Token	Count	Buffer	Dval	DTOG	DVAL	COUNT	SET-UP	IN	OUT	ACK	3	2	1	0	Response	Int

## Absolute Maximum Ratings

Storage Temperature ..... -65 °C to +150 °C  
 Ambient Temperature with Power Applied .... -0 °C to +70 °C  
 Supply Voltage on  $V_{CC}$  Relative to  $V_{SS}$  ..... -0.5 V to +7.0 V  
 DC Input Voltage ..... -0.5 V to + $V_{CC}+0.5$  V  
 DC Voltage Applied to Outputs  
 in High Z State ..... -0.5 V to +  $V_{CC}+0.5$  V  
 Maximum Total Sink Output Current  
 into Port 0 and 1 and Pins ..... 70 mA

Maximum Total Source Output Current into  
 Port 0 and 1 and Pins ..... 30 mA  
 Maximum On-chip Power Dissipation on any  
 GPIO Pin ..... 50 mW  
 Power Dissipation ..... 300 mW  
 Static Discharge Voltage ..... > 2000 V  
 Latch-up Current ..... > 200 mA

## DC Characteristics

FOSC = 6 MHz; Operating Temperature = 0 to 70 °C

	Parameter	Conditions	Min.	Max.	Unit
<b>General</b>					
$V_{CC1}$	Operating Voltage	Note 5	$V_{LVR}$	5.5	V
$V_{CC2}$	Operating Voltage	Note 5	4.35	5.25	V
$I_{CC1}$	$V_{CC}$ Operating Supply Current – Internal Oscillator Mode Typical $I_{CC1}$ = 16 mA <sup>[6]</sup>	$V_{CC}$ = 5.5 V, no GPIO loading  $V_{CC}$ = 5.0 V, T = Room Temperature		20	mA
$I_{CC2}$	$V_{CC}$ Operating Supply Current – External Oscillator Mode Typical $I_{CC2}$ = 13 mA <sup>[6]</sup>	$V_{CC}$ = 5.5 V, no GPIO loading  $V_{CC}$ = 5.0 V, T = Room Temperature		17	mA
$I_{SB1}$	Standby Current – No Wake-up Osc	Oscillator off, D- > 2.7 V		25	μA
$I_{SB2}$	Standby Current – With Wake-up Osc	Oscillator off, D- > 2.7 V		75	μA
$V_{PP}$	Programming Voltage (disabled)		-0.4	0.4	V
$T_{RSNTR}$	Resonator Start-up Interval	$V_{CC}$ = 5.0 V, ceramic resonator		256	μs
$I_{IL}$	Input Leakage Current	Any I/O pin		1	μA
$I_{SNK}$	Max $I_{SS}$ GPIO Sink Current	Cumulative across all ports <sup>[7]</sup>		70	mA
$I_{SRC}$	Max $I_{CC}$ GPIO Source Current	Cumulative across all ports <sup>[7]</sup>		30	mA
<b>Low-Voltage and Power-on Reset</b>					
$V_{LVR}$	Low-Voltage Reset Trip Voltage	$V_{CC}$ below $V_{LVR}$ for >100 ns <sup>[8]</sup>	3.5	4.0	V
$t_{VCCS}$	$V_{CC}$ Power-on Slew Time	linear ramp: 0 to 4 V <sup>[9]</sup>		100	ms
<b>USB Interface</b>					
$V_{REG}$	VREG Regulator Output Voltage	Load = $R_{PU} + R_{PD}$ <sup>[10, 11]</sup>	3.0	3.6	V
$C_{REG}$	Capacitance on VREG Pin	External cap not required		300	pF
$V_{OHU}$	Static Output High, driven	$R_{PD}$ to Gnd <sup>[5]</sup>	2.8	3.6	V

### Notes

- Full functionality is guaranteed in  $V_{CC1}$  range, except USB transmitter specifications and GPIO output currents are guaranteed for  $V_{CC2}$  range.
- Bench measurements taken under nominal operating conditions. Spec cannot be guaranteed at final test.
- Total current cumulative across all Port pins, limited to minimize Power and Ground-Drop noise effects.
- LVR is automatically disabled during suspend mode.
- LVR will re-occur whenever  $V_{CC}$  drops below  $V_{LVR}$ . In suspend or with LVR disabled, BOR occurs whenever  $V_{CC}$  drops below approximately 2.5V.
- $V_{REG}$  specified for regulator enabled, idle conditions (i.e., no USB traffic), with load resistors listed. During USB transmits from the internal SIE, the VREG output is not regulated, and should not be used as a general source of regulated voltage in that case. During receive of USB data, the VREG output drops when D- is LOW due to internal series resistance of approximately 200Ω at the VREG pin.
- In suspend mode,  $V_{REG}$  is only valid if  $R_{PU}$  is connected from D- to VREG pin, and  $R_{PD}$  is connected from D- to ground.

## DC Characteristics

FOSC = 6 MHz; Operating Temperature = 0 to 70 °C (continued)

	Parameter	Conditions	Min.	Max.	Unit
V <sub>OLU</sub>	Static Output Low	With R <sub>PU</sub> to VREG pin		0.3	V
V <sub>OHZ</sub>	Static Output High, idle or suspend	R <sub>PD</sub> connected D– to Gnd, R <sub>PU</sub> connected D– to VREG pin <sup>[5]</sup>	2.7	3.8	V
V <sub>DI</sub>	Differential Input Sensitivity	(D+) – (D–)	0.2		V
V <sub>CM</sub>	Differential Input Common Mode Range		0.8	2.5	V
V <sub>SE</sub>	Single Ended Receiver Threshold		0.8	2.0	V
C <sub>IN</sub>	Transceiver Capacitance			20	pF
I <sub>LO</sub>	Hi-Z State Data Line Leakage	0 V < V <sub>in</sub> < 3.3 V (D+ or D– pins)	–10	10	μA
R <sub>PU</sub>	External Bus Pull-up resistance (D–)	1.3 kΩ ±2% to V <sub>REG</sub> <sup>[12]</sup>	1.274	1.326	kΩ
R <sub>PD</sub>	External Bus Pull-down resistance	15 kΩ ±5% to Gnd	14.25	15.75	kΩ
<b>PS/2 Interface</b>					
V <sub>OLP</sub>	Static Output Low	I <sub>sink</sub> = 5 mA, SDATA or SCLK pins		0.4	V
R <sub>PS2</sub>	Internal PS/2 Pull-up Resistance	SDATA, SCLK pins, PS/2 Enabled	3	7	kΩ
<b>General Purpose I/O Interface</b>					
R <sub>UP</sub>	Pull-up Resistance		8	24	kΩ
V <sub>ICR</sub>	Input Threshold Voltage, CMOS mode	Low to high edge, Port 0 or 1	40%	60%	V <sub>CC</sub>
V <sub>ICF</sub>	Input Threshold Voltage, CMOS mode	High to low edge, Port 0 or 1	35%	55%	V <sub>CC</sub>
V <sub>HC</sub>	Input Hysteresis Voltage, CMOS mode	High to low edge, Port 0 or 1	3%	10%	V <sub>CC</sub>
V <sub>ITTL</sub>	Input Threshold Voltage, TTL mode	Ports 0, 1, and 2	0.8	2.0	V
V <sub>OL1A</sub>	Output Low Voltage, high drive mode	I <sub>OL1</sub> = 50 mA, Ports 0 or 1 <sup>[5]</sup>		0.8	V
V <sub>OL1B</sub>		I <sub>OL1</sub> = 25 mA, Ports 0 or 1 <sup>[5]</sup>		0.4	V
V <sub>OL2</sub>	Output Low Voltage, medium drive mode	I <sub>OL2</sub> = 8 mA, Ports 0 or 1 <sup>[5]</sup>		0.4	V
V <sub>OL3</sub>	Output Low Voltage, low drive mode	I <sub>OL3</sub> = 2 mA, Ports 0 or 1 <sup>[5]</sup>		0.4	V
V <sub>OH</sub>	Output High Voltage, strong drive mode	Port 0 or 1, I <sub>OH</sub> = 2 mA <sup>[5]</sup>	V <sub>CC</sub> –2		V
R <sub>XIN</sub>	Pull-down resistance, XTALIN pin	Internal Clock Mode only	50		kΩ

### Note

12. The 200Ω internal resistance at the VREG pin gives a standard USB pull-up using this value. Alternately, a 1.5 kΩ, 5% pull-up from D– to an external 3.3V supply can be used.

## Switching Characteristics

Parameter	Description	Conditions	Min.	Max.	Unit
<b>Internal Clock Mode</b>					
F <sub>ICLK</sub>	Internal Clock Frequency	Internal Clock Mode enabled	5.7	6.3	MHz
F <sub>ICLK2</sub>	Internal Clock Frequency, USB mode	Internal Clock Mode enabled, Bit 2 of register 0xF8h is set (Precision USB Clocking) <sup>[13]</sup>	5.91	6.09	MHz
<b>External Oscillator Mode</b>					
T <sub>CYC</sub>	Input Clock Cycle Time	USB Operation, with External ±1.5% Ceramic Resonator or Crystal	164.2	169.2	ns
T <sub>CH</sub>	Clock HIGH Time		0.45 t <sub>CYC</sub>		ns
T <sub>CL</sub>	Clock LOW Time		0.45 t <sub>CYC</sub>		ns
<b>Reset Timing</b>					
t <sub>START</sub>	Time-out Delay after LVR/BOR		24	60	ms
t <sub>WAKE</sub>	Internal Wake-up Period	Enabled Wake-up Interrupt <sup>[14]</sup>	1	5	ms
t <sub>WATCH</sub>	WatchDog Timer Period	F <sub>OSC</sub> = 6 MHz	10.1	14.6	ms
<b>USB Driver Characteristics</b>					
T <sub>R</sub>	Transition Rise Time	C <sub>Load</sub> = 200 pF (10% to 90%) <sup>[5]</sup>	75		ns
T <sub>R</sub>	Transition Rise Time	C <sub>Load</sub> = 600 pF (10% to 90%) <sup>[5]</sup>		300	ns
T <sub>F</sub>	Transition Fall Time	C <sub>Load</sub> = 200 pF (10% to 90%) <sup>[5]</sup>	75		ns
T <sub>F</sub>	Transition Fall Time	C <sub>Load</sub> = 600 pF (10% to 90%) <sup>[5]</sup>		300	ns
T <sub>RFM</sub>	Rise/Fall Time Matching	t <sub>r</sub> /t <sub>f</sub> <sup>[5, 15]</sup>	80	125	%
V <sub>CRS</sub>	Output Signal Crossover Voltage <sup>[19]</sup>	C <sub>Load</sub> = 200 to 600 pF <sup>[5]</sup>	1.3	2.0	V
<b>USB Data Timing</b>					
T <sub>DRATE</sub>	Low Speed Data Rate	Ave. Bit Rate (1.5 Mb/s ±1.5%)	1.4775	1.5225	Mb/s
T <sub>DJR1</sub>	Receiver Data Jitter Tolerance	To Next Transition <sup>[16]</sup>	–75	75	ns
T <sub>DJR2</sub>	Receiver Data Jitter Tolerance	For Paired Transitions <sup>[16]</sup>	–45	45	ns
T <sub>DEOP</sub>	Differential to EOP transition Skew	Note 16	–40	100	ns
T <sub>EOPR2</sub>	EOP Width at Receiver	Accepts as EOP <sup>[16]</sup>	670		ns
T <sub>EOPT</sub>	Source EOP Width		1.25	1.50	μs
T <sub>UDJ1</sub>	Differential Driver Jitter	To next transition, <a href="#">Figure 46</a>	–95	95	ns
T <sub>UDJ2</sub>	Differential Driver Jitter	To paired transition, <a href="#">Figure 46</a>	–150	150	ns
T <sub>LST</sub>	Width of SE0 during Diff. Transition			210	ns
<b>Non-USB Mode Driver Characteristics</b>					
T <sub>FPS2</sub>	SDATA/SCK Transition Fall Time	Note 17 C <sub>Load</sub> = 150 pF to 600 pF	50	300	ns
<b>SPI Timing</b>					
T <sub>SMCK</sub>	SPI Master Clock Rate	See Figures 47 to 50 <sup>[18]</sup> F <sub>CLK</sub> /3; see <a href="#">Figure 20</a>		2	MHz
T <sub>SSCK</sub>	SPI Slave Clock Rate			2.2	MHz

### Notes

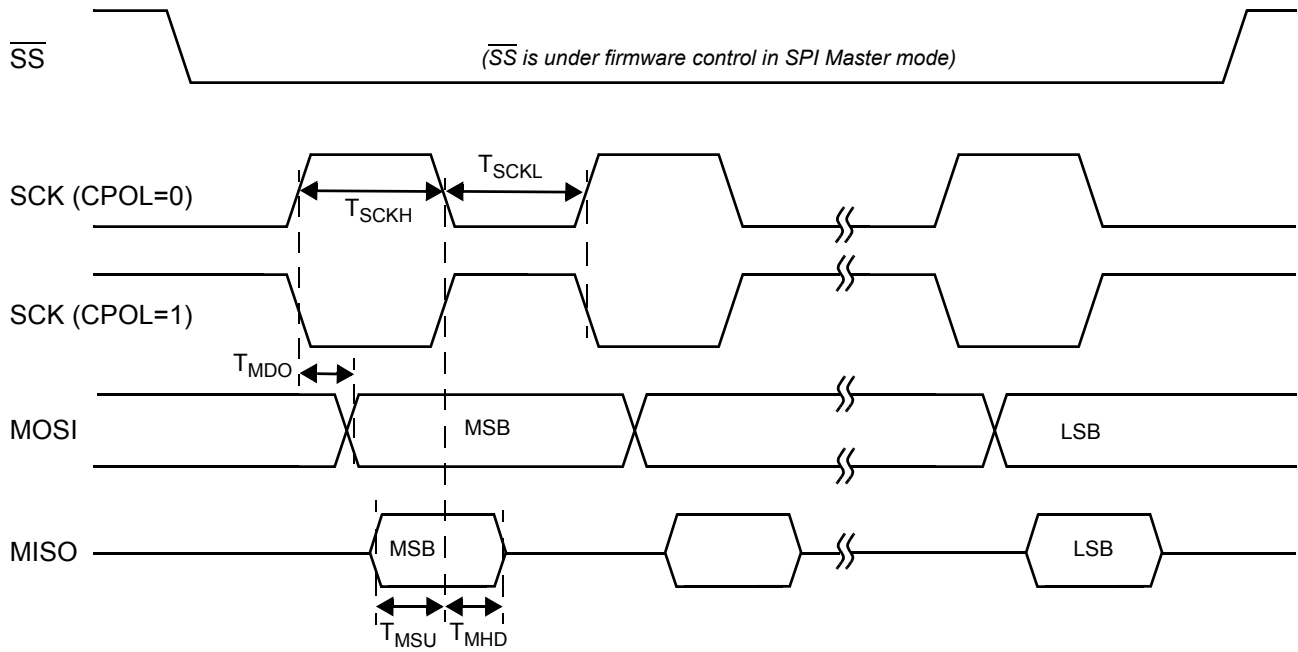

13. Initially F<sub>ICLK2</sub> = F<sub>ICLK</sub> until a USB packet is received.
14. Wake-up time for Wake-up Adjust Bits cleared to 000b (minimum setting)
15. Tested at 200 pF.
16. Measured at cross-over point of differential data signals.
17. Non-USB Mode refers to driving the D–/SDATA and/or D+/SCLK pins with the Control Bits of the USB Status and Control Register, with Control Bit 2 HIGH.
18. SPI timing specified for capacitive load of 50 pF, with GPIO output mode = 01 (medium low drive, strong high drive).
19. Per the USB 2.0 Specification, Table 7.7, Note 10, the first transition from the Idle state is excluded.

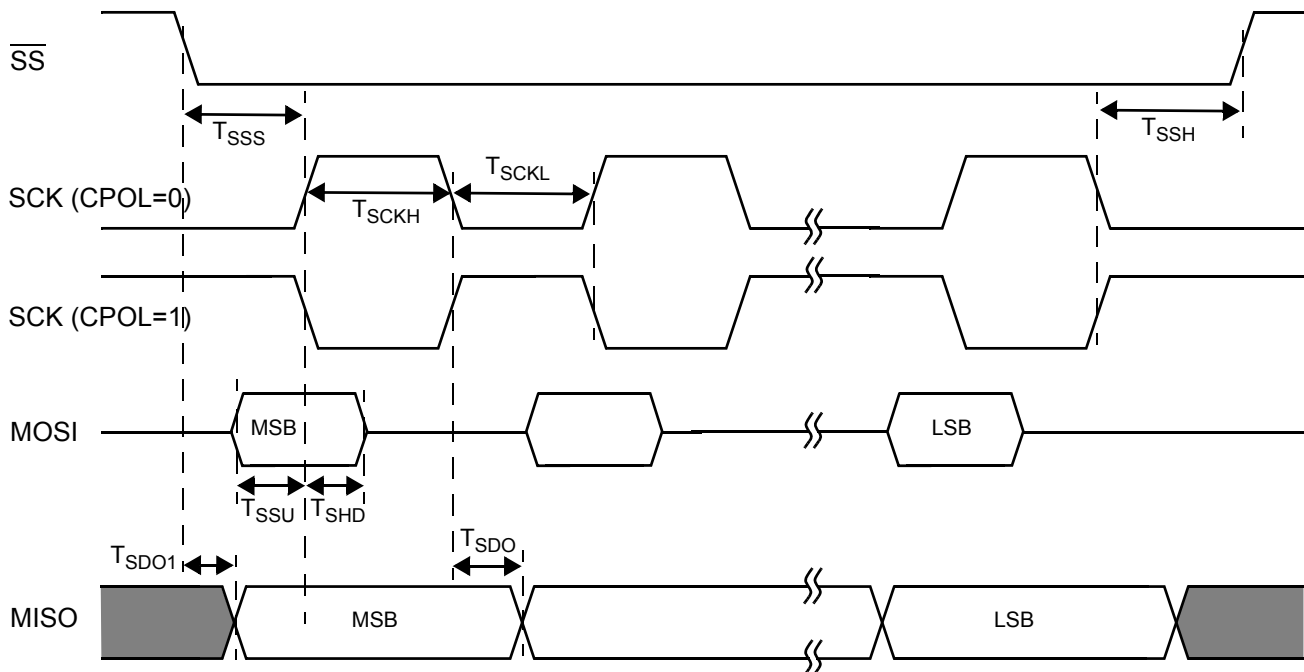

**Switching Characteristics** (continued)

Parameter	Description	Conditions	Min.	Max.	Unit
$T_{SCKH}$	SPI Clock High Time	High for CPOL = 0, Low for CPOL = 1	125		ns
$T_{SCKL}$	SPI Clock Low Time	Low for CPOL = 0, High for CPOL = 1	125		ns
$T_{MDO}$	Master Data Output Time	SCK to data valid	-25	50	ns
$T_{MDO1}$	Master Data Output Time, First bit with CPHA = 1	Time before leading SCK edge	100		ns
$T_{MSU}$	Master Input Data Set-up time		50		ns
$T_{MHD}$	Master Input Data Hold time		50		ns

25	P0.4	980.35	2843.15

## Errata

This section describes the errata for the enCoRe™ USB Combination Low-speed USB & PS/2 Peripheral Controller / CY7C637xx. The details include errata trigger conditions, available workaround, and silicon revision applicability.

Please contact your local Cypress Sales Representative if you have further questions.

### Part Numbers Affected

Part Number	Device Characteristics
CY7C63722	All packages
CY7C63723	All packages
CY7C63743	All packages

### enCoRe™ USB Combination Low-speed USB & PS/2 Peripheral Controller Qualification Status

Product status: In Production - Qual report: 001406

### enCoRe™ USB Combination Low-speed USB & PS/2 Peripheral Controller Errata Summary

The following table defines the errata applicability to available enCoRe™ USB Combination Low-speed USB & PS/2 Peripheral Controller family devices. An "X" indicates that the errata pertains to the selected device.

Note: Errata titles are hyperlinked. Click on table entry to jump to description.

Items	CY7C637xx	Rev Letter	Fix Status
1. Faulty GPIO Interrupt	X	A	No silicon fix planned.

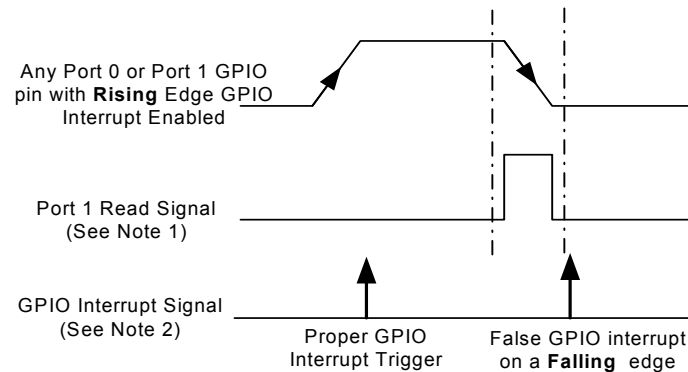

#### 1. Faulty GPIO Interrupt

##### ■ Problem Definition

When a falling edge interrupt is enabled for a GPIO pin, reading the GPIO Port 1 coincident to a rising edge of that GPIO signal may generate a false GPIO interrupt.

When a rising edge interrupt is enabled for a GPIO pin, reading the GPIO Port 1 coincident to a falling edge of that GPIO signal may generated a false GPIO interrupt.

**Note 1:** Port 1 Read is an internal signal that is asserted when Port 1 is read with an "IORD 01h" instruction.

**Note 2:** The GPIO Interrupt signal is an internal signal. The arrow indicates that a GPIO interrupt is triggered.

#### ■ Parameters Affected

Interrupts

#### ■ Trigger Condition(S)

Reading the GPIO Port 1 when either rising or falling edge interrupts are enabled for a GPIO pin.

#### ■ Scope of Impact

The chip enters the GPIO Interrupt Service Routine (ISR) in error.

#### ■ Workaround

Workarounds will need to be tailored to individual applications based on the flexibility of changing the GPIO usage, the timing of the GPIO interrupt sources and firmware interrupt latencies.

#### ■ Fix Status

No silicon fix is planned.

## Document History Page

Document Title: CY7C63722C/CY7C63723C/CY7C63743C, enCoRe™ USB Combination Low-Speed USB and PS/2 Peripheral Controller Document Number: 38-08022				
Rev.	ECN No.	Issue Date	Orig. of Change	Description of Change
**	118643	10/22/02	BON	Converted from Spec 38-00944 to Spec 38-08022. Added notes 17, 18 to section 26 Removed obsolete parts (63722-PC and 63742) Added die sale Added section 23 (Register Summary)
*A	243308	SEE ECN	KKU	Added 24 QSOP package Added Lead-free packages to section 27 Reformatted to update format
*B	267229	See ECN	ARI	Corrected part number in the Ordering Information section
*C	429169	See ECN	TYJ	Updated part numbers with 'C' part numbers Changed to 'Cypress Perform' logo Added the 24-QSOP part offering
*D	3057657	10/13/2010	AJHA	Added "Not recommended for new designs" watermark in the PDF. Updated package diagrams. Updated template.
*E	3229083	04/15/2011	NXZ	Package diagram updated 51-85025 *E Completing Sunset Review.
*F	3593602	04/20/2012	ANTG	Added Not recommended for New Designs" watermark in the PDF. Updated cross-references for figures and sections throughout the datasheet. Updated <a href="#">Package Diagrams</a> 51-85010, 51-85023, 51-85013, and 51-85055 (from Rev *C to *D). Added Table of Contents.
*G	3997628	05/11/2013	SELV	Updated <a href="#">Package Diagrams</a> : spec 51-85010 – Changed revision from *D to *E.  Added <a href="#">Errata</a> .
*H	4072605	07/22/2013	SELV	Added Errata footnote (Note 1).  Updated <a href="#">Functional Overview</a> : Updated <a href="#">enCoRe USB—The New USB Standard</a> : Added Note 1 and referred the same note at the end of the sentence "The interrupt polarity can be either rising or falling edge".  Updated to new template.
*I	4313900	03/21/2014	AKSL	Added CY7C63743C-SXCT and CY7C63723C-SXCT in <a href="#">Ordering Information</a> . Updated 24-pin SOIC package diagram. Removed "Not recommended for new designs" watermark.
*J	4910453	09/07/2015	KISB	Updated <a href="#">DC Characteristics</a> : Changed maximum value of V <sub>OHZ</sub> parameter from 3.6 V to 3.8 V. Updated <a href="#">Package Diagrams</a> : spec 51-85023 – Changed revision from *D to *E. spec 51-85013 – Changed revision from *D to *E. spec 51-85055 – Changed revision from *D to *E. Updated to new template.
*K	5705418	04/21/2017	AESATMP8	Updated logo and Copyright.

## Sales, Solutions, and Legal Information

### Worldwide Sales and Design Support

Cypress maintains a worldwide network of offices, solution centers, manufacturer's representatives, and distributors. To find the office closest to you, visit us at [Cypress Locations](#).
