## 1. FEATURES

- 8G-bit SLC NAND Flash
    - Stacked by two 4Gb die
    - Bus: x8
    - Page size: (2048+64) byte,
    - Block size: (128K+4K) byte,
    - Plane size:  
2048-block/plane x 2 per die
  - **ONFI 1.0 compliant**
  - **Multiplexed Command/Address/Data**
  - **User Redundancy**
    - 64-byte attached to each page
  - **Fast Read Access**
    - Latency of array to register: 25us
    - Sequential read: 20ns
  - **Cache Read Support**
  - **Page Program Operation**
    - Page program time: 300us (typ.)
  - **Cache Program Support**
  - **Block Erase Operation**
    - Block erase time: 1ms (typ.)
  - **Single Voltage Operation:**
    - VCC: 2.7 - 3.6V
  - **Low Power Dissipation**
    - Max. 30mA  
Active current (Read/Program/Erase)
  - **Sleep Mode**
    - 100uA (Max) standby current
  - **Hardware Data Protection:** WP# pin
  - **Device Status Indicators**
    - Ready/Busy (R/B#) pin
    - Status Register
  - **Chip Enable Don't Care**
    - Simplify System Interface
  - **Unique ID Read support (ONFI)**
  - **Secure OTP support**
  - **Electronic Signature (5 Cycles)**
  - **High Reliability**
    - Endurance: typical 100K cycles (with 4-bit ECC per (512+16) Byte)
    - Data Retention: 10 years
  - **Wide Temperature Operating Range**
    - 40°C to +85°C
  - **Package:**
    - 1) 48-TSOP(I) (12mm x 20mm)
    - 2) 63-ball 9mmx11mm VFBGA
- All packaged devices are RoHS Compliant and Halogen-free.

## 2. GENERAL DESCRIPTIONS

The MX60LF8G18AC is an 8Gb SLC NAND Flash memory device. Its standard NAND Flash features and reliable quality of typical P/E cycles 100K (with ECC), which makes it most suitable for embedded system code and data storage.

The product family requires 4-bit ECC per (512+16)B.

The MX60LF8G18AC is typically accessed in pages of 2,112 bytes for read and program operations.

The MX60LF8G18AC array is organized as thousands of blocks, which is composed by 64 pages of (2,048+64) byte in two NAND strings structure with 32 serial connected cells in each string. Each page has an additional 64 bytes for ECC and other purposes. The device has an on-chip buffer of 2,112 bytes for data load and access.

The Cache Read Operation of the MX60LF8G18AC enables first-byte read-access latency of 25us and sequential read of 20ns and the latency time of next sequential page will be shorten from tR to tRCBSY.

The MX60LF8G18AC power consumption is 30mA during all modes of operations (Read/Program/Erase), and 100uA in standby mode.

**Figure 1. Logic Diagram**

## 2-1. ORDERING INFORMATION

### Part Name Description

Please contact our regional sales for the latest product selection and available form factors.

| Part Number      | Density | Organization | VCC Range | Package  | Temperature Grade |
|------------------|---------|--------------|-----------|----------|-------------------|
| MX60LF8G18AC-TI  | 8Gb     | x8           | 3V        | 48-TSOP  | Industrial        |
| MX60LF8G18AC-XKI | 8Gb     | x8           | 3V        | 63-VFBGA | Industrial        |

### 3. PIN CONFIGURATIONS

#### 48-TSOP

**Note 1.** These pins might not be connected internally. However, it is recommended to connect these pins to power(or ground) as designated for ONFI compatibility.

## 63-ball 9mmx11mm VFBGA

**Note 1.** These pins might not be connected internally; however, it is recommended to connect these pins to power (or ground) as designated for ONFI compatibility.

### 3-1. PIN DESCRIPTIONS

| SYMBOL           | PIN NAME                          |
|------------------|-----------------------------------|
| <b>IO7 - IO0</b> | Data I/O port                     |
| <b>CE#</b>       | Chip Enable (Active Low)          |
| <b>RE#</b>       | Read Enable (Active Low)          |
| <b>WE#</b>       | Write Enable (Active Low)         |
| <b>CLE</b>       | Command Latch Enable              |
| <b>ALE</b>       | Address Latch Enable              |
| <b>WP#</b>       | Write Protect (Active Low)        |
| <b>R/B#</b>      | Ready/Busy (Open Drain)           |
| <b>VSS</b>       | Ground                            |
| <b>VCC</b>       | Power Supply for Device Operation |
| <b>NC</b>        | Not Connected Internally          |
| <b>DNU</b>       | Do Not Use (Do Not Connect)       |

**PIN FUNCTIONS**

The MX60LF8G18AC device is a sequential access memory that utilizes multiplexing input of Command/Address/Data.

**I/O PORT: IO7 - IO0**

The IO7 to IO0 pins are for address/command input and data output to/from the device.

**CHIP ENABLE: CE#**

The device goes into low-power Standby Mode when CE# goes high during a read operation and not at busy stage.

The CE# goes low to enable the device to be ready for standard operation. When the CE# goes high, the device is deselected. However, when the device is at busy stage, the device will not go to standby mode when CE# pin goes high.

**READ ENABLE: RE#**

The RE# (Read Enable) allows the data to be output by a tREA time after the falling edge of RE#. The internal address counter is automatically increased by one at the falling edge of RE#.

**WRITE ENABLE: WE#**

When the WE# goes low, the address/data/command are latched at the rising edge of WE#.

**COMMAND LATCH ENABLE: CLE**

The CLE controls the command input. When the CLE goes high, the command data is latched at the rising edge of the WE#.

**ADDRESS LATCH ENABLE: ALE**

The ALE controls the address input. When the ALE goes high, the address is latched at the rising edge of WE#.

**WRITE PROTECT: WP#**

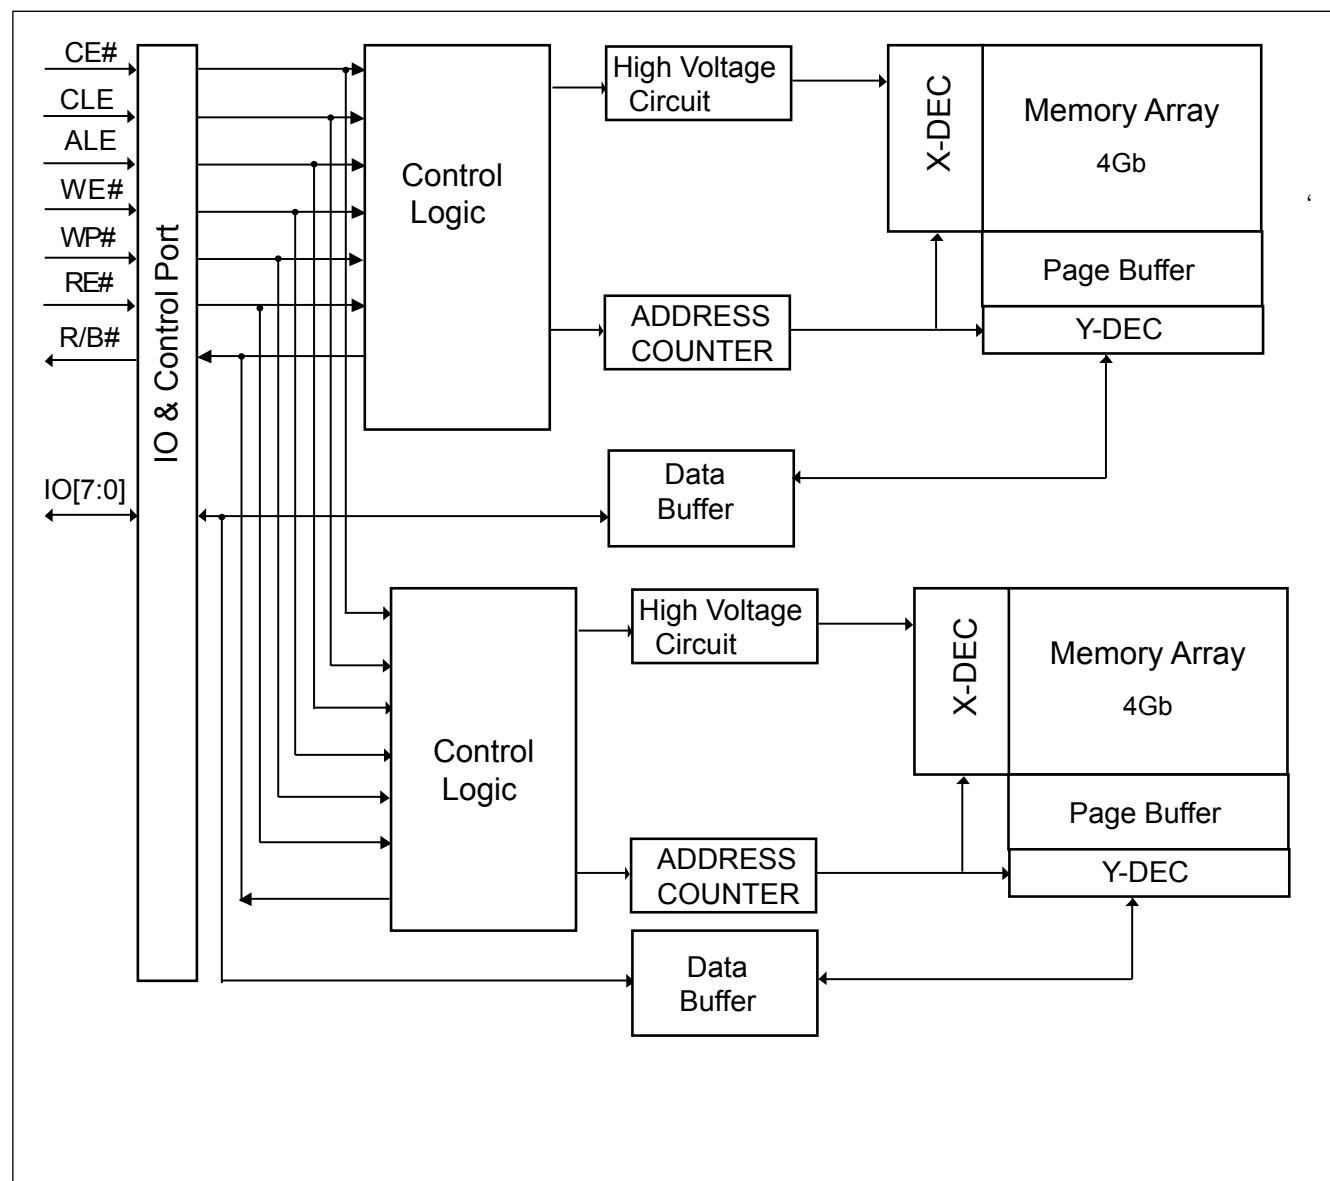

The WP# signal keeps low and then the memory will not accept the program/erase operation. It is recommended to keep WP# pin low during power on/off sequence. Please refer to the waveform of "Power On/Off Sequence".

**READY/Busy: R/B#**

The R/B# is an open-drain output pin. The R/B# outputs the ready/busy status of read/program/erase operation of the device. When the R/B# is at low, the device is busy for read or program or erase operation. When the R/B# is at high, the read/program/erase operation is finished.

Please refer to **Section 9-1** for details.

## 4. BLOCK DIAGRAM

## 5. SCHEMATIC CELL LAYOUT AND ADDRESS ASSIGNMENT

MX60LF8G18AC NAND device is stacked by two 4Gb die and each die is divided into two planes, which is composed by 64 pages of (2,048+64)-byte in two NAND strings structure with 32 serial connected cells in each string. Each page has an additional 64 bytes for ECC and other purposes. The device has an on-chip buffer of 2,112 bytes for data load and access. Each 2K-Byte page has the two area, one is the main area which is 2048-bytes and the other is spare area which is 64-byte.

There are five address cycles for the address allocation, please refer to the table below.

**Table 1-1. Address Allocation**

| Addresses                  | IO7 | IO6              | IO5 | IO4 | IO3 | IO2              | IO1 | IO0 |
|----------------------------|-----|------------------|-----|-----|-----|------------------|-----|-----|
| Column address - 1st cycle | A7  | A6               | A5  | A4  | A3  | A2               | A1  | A0  |
| Column address - 2nd cycle | L   | L                | L   | L   | A11 | A10              | A9  | A8  |
| Row address - 3rd cycle    | A19 | A18 <sup>1</sup> | A17 | A16 | A15 | A14              | A13 | A12 |
| Row address - 4th cycle    | A27 | A26              | A25 | A24 | A23 | A22              | A21 | A20 |
| Row address - 5th cycle    | L   | L                | L   | L   | L   | A30 <sup>2</sup> | A29 | A28 |

**Notes:**

1. A18 is the plane selection.
2. A30 is the die selection. A30 = 0 is for bottom 4Gb, A30 = 1 for top 4Gb.

## 6. DEVICE OPERATIONS

### 6-1. Address Input/Command Input/Data Input

Address input bus operation is for address input to select the memory address. The command input bus operation is for giving command to the memory. The data input bus is for data input to the memory device.

**Figure 2. AC Waveforms for Command / Address / Data Latch Timing**

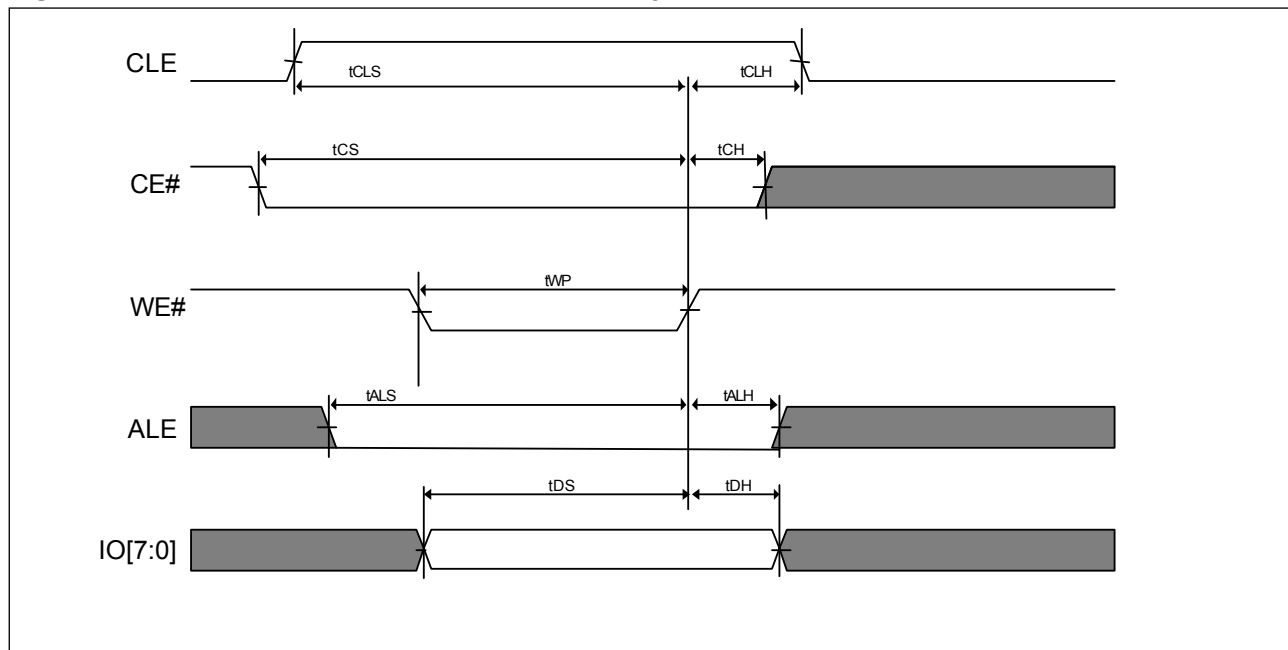

**Figure 3. AC Waveforms for Address Input Cycle**

**Figure 4. AC Waveforms for Command Input Cycle**

**Figure 5. AC Waveforms for Data Input Cycle**

## 6-2. Page Read

The MX60LF8G18AC array is accessed in Page of 2,112 bytes. External reads begins after the R/B# pin goes to READY.

The Read operation may also be initiated by writing the 00h command and giving the address (column and row address) and being confirmed by the 30h command, the MX60LF8G18AC begins the internal read operation and the chip enters busy state. The data can be read out in sequence after the chip is ready. Refer to the waveform for Read Operation as below.

If the host side uses a sequential access time ( $t_{RC}$ ) of less than 30ns, the data can be latched on the next falling edge of RE# as the waveform of EDO mode (**Figure 9-2**).

To access the data in the same page randomly, a command of 05h may be written and only column address following and then confirmed by E0h command.

**Figure 6. AC Waveforms for Read Cycle**

**Figure 7. AC Waveforms for Read Operation (Intercepted by CE#)**

**Figure 8. AC Waveforms for Read Operation (with CE# Don't Care)**

**Note:** The CE# "Don't Care" feature may simplify the system interface, which allows controller to directly download the code from flash device, and the CE# transitions will not stop the read operation during the latency time.

**Figure 9-1. AC Waveforms for Sequential Data Out Cycle (After Read)**

**Figure 9-2. AC Waveforms for Sequential Data Out Cycle (After Read) - EDO Mode**

**Figure 10. AC Waveforms for Random Data Output**

### 6-3. Cache Read Sequential

The cache read sequential operation is for throughput enhancement by using the internal cache buffer. It allows the consecutive pages to be read-out without giving next page address, which reduces the latency time from  $t_R$  to  $t_{RCBSY}$  between pages or blocks. While the data is read out on one page, the data of next page can be read into the cache buffer.

After writing the 00h command, the column and row address should be given for the start page selection, and followed by the 30h command for address confirmation. After that, the CACHE READ operation starts after a latency time  $t_R$  and following a 31h command with the latency time of  $t_{RCBSY}$ , the data can be read-out sequentially from 1<sup>st</sup> column address (A[11:0]=00h) without giving next page address input. The 31h command is necessary to confirm the next cache read sequential operation and followed by a  $t_{RCBSY}$  latency time before next page data is necessary. The CACHE READ SEQUENTIAL command is also valid for the consecutive page cross block.

The random data out (05h-E0h) command set is available to change the column address of the current page data in the cache register.

The user can check the chip status by the following method:

- R/B# pin ("0" means the data is not ready, "1" means the user can read the data)
- Status Register (SR[6] functions the same as R/B# pin, SR[5] indicates the internal chip operation, "0" means the chip is in internal operation and "1" means the chip is idle.) Status Register can be checked after the Read Status command (70h) is issued. Command 00h should be given to return to the cache read sequential operation.

To confirm the last page to be read-out during the cache read sequential operation, a 3Fh command is needed to replace the 31h command prior to the last data-out.

When the cache read operation is applied to the die boundary, there is a restriction - the 31h (cache read sequential) command should not be issue to cross the die boundary. However, the 3Fh (cache read end) command is accepted on the die boundary.

**Figure 11-1. AC Waveforms for Cache Read Sequential**

## 6-4. Cache Read Random

The main difference from the Cache Read Sequential operation is the Cache Read Random operation may allow the random page to be read-out with cache operation not just for the consecutive page only.

After writing the 00h command, the column and row address should be given for the start page selection, and followed by the 30h command for address confirmation. The column address is ignored in the cache read random operation. And then, the CACHE READ RANDOM operation starts after a latency time  $t_R$  and following a 00h command with the selected page address and following a 31h command, the data can be read-out after the latency time of  $t_{RCBSY}$ . After the previous selected page data out, a new selected page address can be given by writing the 00h-31h command set again. The CACHE READ RANDOM command is also valid for the consecutive page cross block.

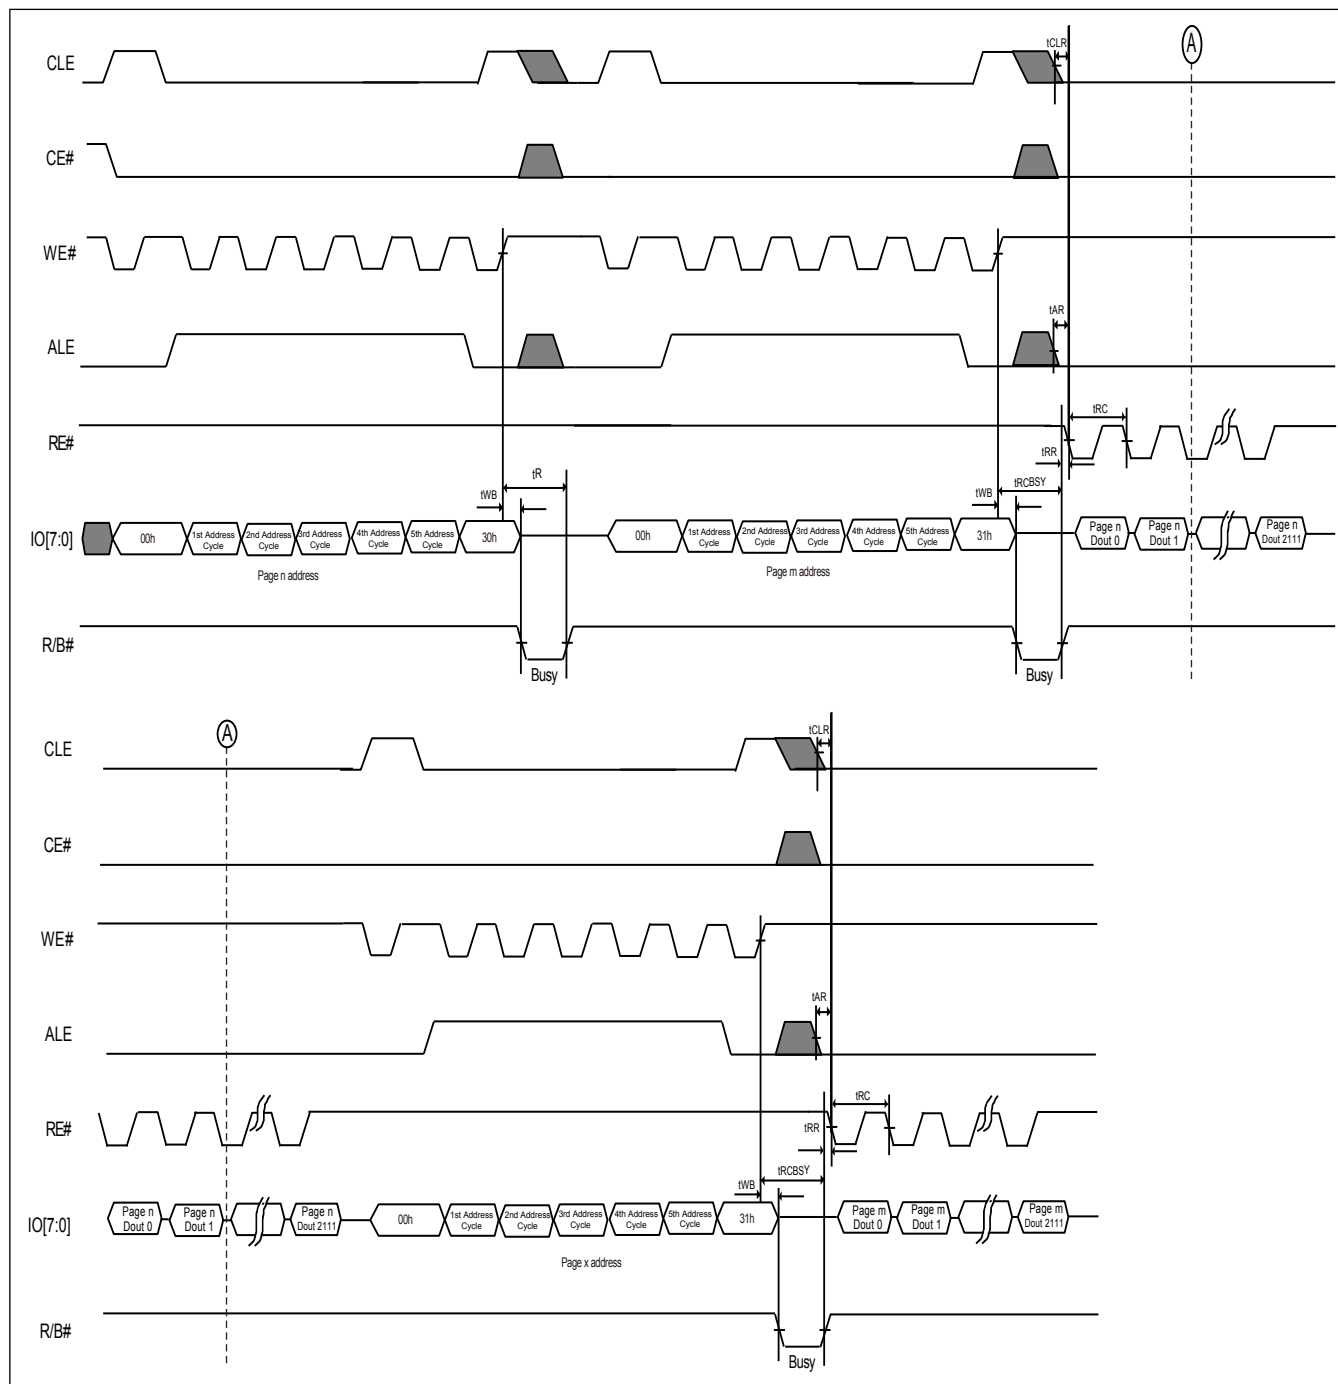

The random data out (05h-E0h) command set is available to change the column address of the current page data in the cache register.

The user can check the chip status by the following method:

- R/B# pin ("0" means the data is not ready, "1" means the user can read the data)
- Status Register can be checked after the Read Status command (70h) is issued. (SR[6] behaves the same as R/B# pin, SR[5] indicates the internal chip operation, "0" means the chip is in internal operation and "1" means the chip is idle.) Command 00h should be given to return to the cache read operation.

To confirm the last page to be read-out during the cache read operation, a 3Fh command is needed to replace the 31h command prior to the last data-out.

**Figure 11-2. AC Waveforms for Cache Read Random**

## 6-5. Page Program

The memory is programmed by page, which is 2,112 bytes. After Program load command (80h) is issued and the row and column address is given, the data will be loaded into the chip sequentially. Random Data Input command (85h) allows multi-data load in non-sequential address. After data load is complete, program confirm command (10h) is issued to start the page program operation. The page program operation in a block should start from the low address to high address. Partial program in a page is allowed up to 4 times. However, the random data input mode for programming a page is allowed and number of times is not limited.

The status of the program completion can be detected by R/B# pin or Status register bit SR[6].

The program result is shown in the chip status bit (SR[0]). SR[0] = 1 indicates the Page Program is not successful and SR[0] = 0 means the program operation is successful.

During the Page Program progressing, only the read status register command and reset command are accepted, others are ignored.

**Figure 12. AC Waveforms for Program Operation after Command 80H**

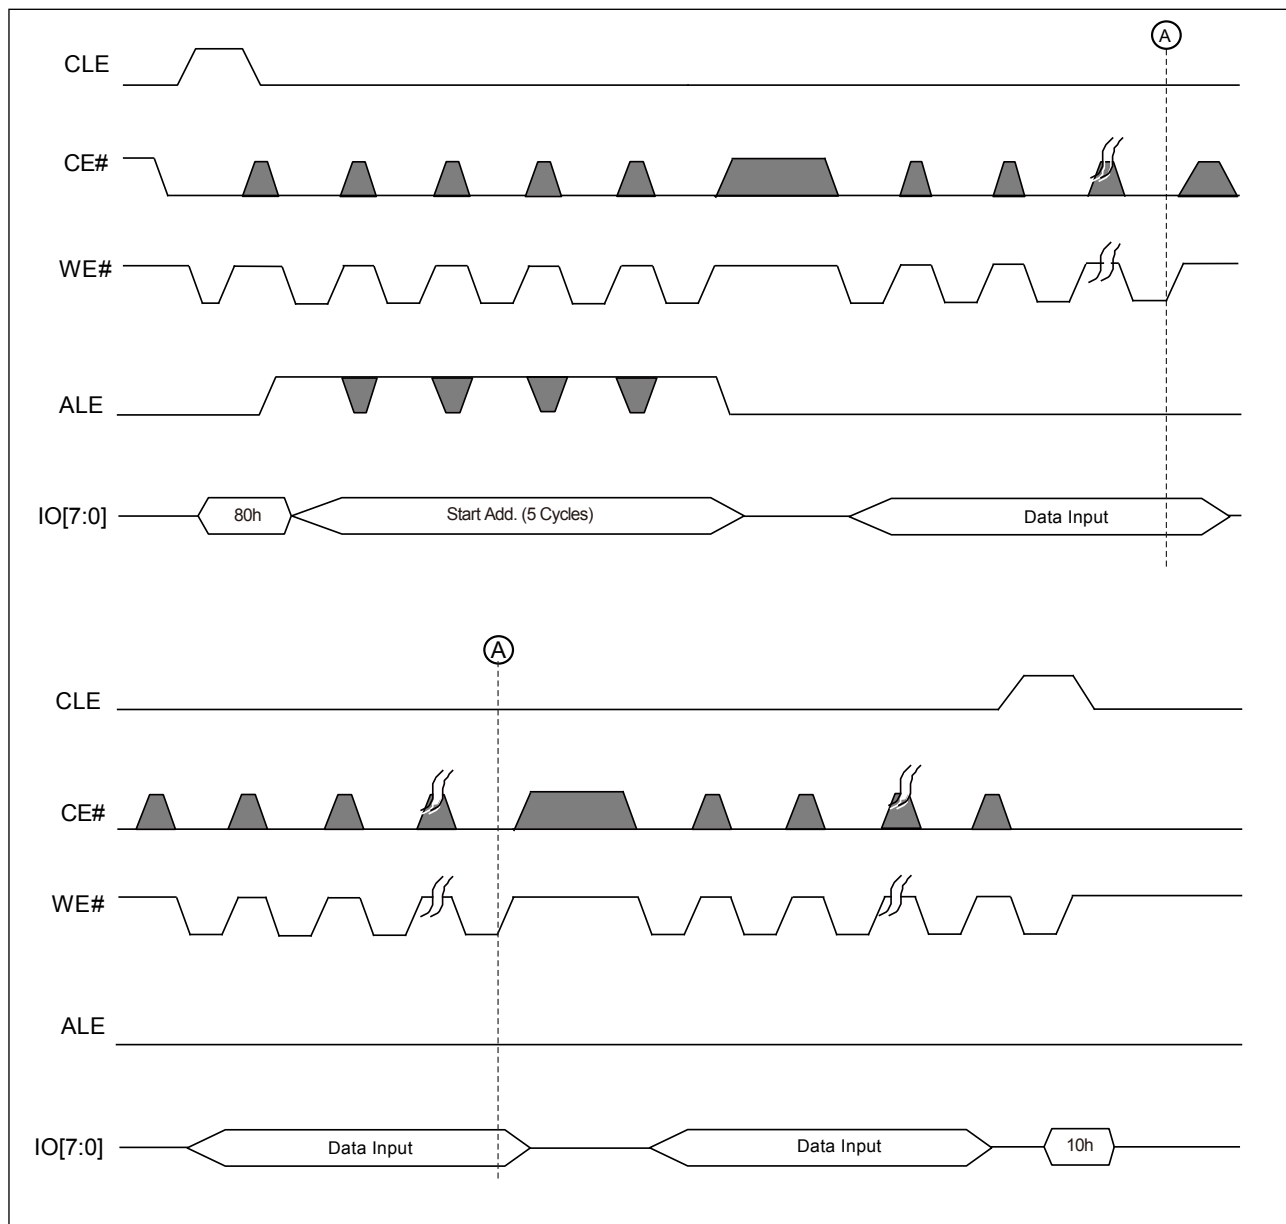

Figure 13. AC Waveforms for Random Data In (For Page Program)

**Note:** Random Data In is also supported in cache program.

**Figure 14. AC Waveforms for Program Operation with CE# Don't Care**

**Note:** The CE# "Don't Care" feature may simplify the system interface, which allows the controller to directly write data into flash device, and the CE# transitions will not stop the program operation during the latency time.

## 6-6. Cache Program

The cache program feature enhances the program performance by using the cache buffer of 2,112-byte.

The serial data can be input to the cache buffer while the previous data stored in the buffer are programming into the memory cell. Cache Program command sequence is almost the same as page program command sequence. Only the Program Confirm command (10h) is replaced by cache Program command (15h).

After the Cache Program command (15h) is issued. The user can check the status by the following methods.

- R/B# pin
- Cache Status Bit (SR[6] = 0 indicates the cache is busy; SR[6] = 1 means the cache is ready).

The user can issue another Cache Program Command Sequence after the Cache is ready. The user can always monitor the chip state with Ready/Busy Status Bit (SR[5]) by issuing the 70h or 78h command to read status. To use the Status Enhanced Read (78h) for reading each die status if the cross die cache program operation failed. The user can issues either program confirm command (10h) or cache program command (15h) for the last page if the user monitor the chip status by issuing Read Status Command (70h).

However, if the user only monitors the R/B# pin, the user needs to issue the program confirm command (10h) for the last page.

The user can check the Pass/Fail Status through P/F Status Bit (SR[0]) and Cache P/F Status Bit (SR[1]). SR[1] represents Pass/Fail Status of the previous page. SR[1] is updated when SR[6] change from 0 to 1 or Chip is ready. SR[0] shows the Pass/Fail status of the current page. It is updated when SR[5] change from "0" to "1" or the end of the internal programming. For more details, please refer to the related waveforms.

**Figure 15-1. AC Waveforms for Cache Program**

Figure 15-2. AC Waveforms for Sequence of Cache Program

**Note:**  $t_{PROG} = \text{Page}_{(Last)} \text{ programming time} + \text{Page}_{(Last-1)} \text{ programming time} - \text{Input cycle time of command \& address} - \text{Data loading time of page}_{(Last)}$ .

## 6-7. Block Erase

The MX60LF8G18AC supports a block erase command. This command will erase a block of 64 pages associated with the most significant address bits.

The completion of the erase operation can be detected by R/B# pin or Status register bit (IO6). Recommend to check the status register bit IO0 after the erase operation completes.

During the erasing process, only the read status register command and reset command can be accepted, others are ignored.

**Figure 16. AC Waveforms for Erase Operation**

## 6-8. ID Read

The device contains ID codes that identify the device type and the manufacturer. This command is valid only when internal all die are ready. The ID READ command sequence includes one command Byte (90h), one address byte (00h). The Read ID command 90h may provide the manufacturer ID (C2h) of one-byte and device ID (D3h) of one-byte, also Byte2, Byte3, and Byte4 ID code are followed.

The device support ONFI Parameter Page Read, by sending the ID Read (90h) command and following one byte address (20h), the four-byte data returns the value of 4Fh-4Eh-46h-49h for the ASCII code of "O"- "N"- "F"- "I" to identify the ONFI parameter page.

**Table 2. ID Codes Read Out by ID Read Command 90H**

| 8Gb                | 8Gb, x8, 3V |
|--------------------|-------------|
| Byte0-Manufacturer | C2h         |
| Byte1: Device ID   | D3h         |
| Byte2              | D1h         |
| Byte3              | 95h         |
| Byte4              | 5Ah         |

Note: See also Table 2. ID Codes Read Out by ID Read Command 90H.

Figure 17-2. AC Waveforms for ID Read (ONFI Identifier) Operation

## 6-9. Status Read

The MX60LF8G18AC provides a status register that outputs the device status by writing a command code 70h, and then the IO pins output the status at the falling edge of CE# or RE# which occurs last. Even though when multiple flash devices are connecting in system and the R/B#pins are common-wired, the two lines of CE# and RE# may be checked for individual devices status separately.

The 8Gb has two dies in a package. The status read command will only output the status of the latest selected die. To avoid the data-bus contention, the status read command should not be used on the interleaved operation. The status enhanced read command can be used for the status check during/after multi-die operations.

The status read command 70h will keep the device at the status read mode unless next valid command is issued. The resulting information is outlined in **Table 4.** as below.

**Table 4. Status Output**

| Pin     | Status                                 | Related Mode   | Value        |                |
|---------|--|--|--------------|----------------|
| SR[0]   | Chip Status                            | Page Program, Cache Program (Page N), Block Erase  | 0: Passed    | 1: Failed      |
| SR[1]   | Cache Program Result                   | Cache Program (Page N-1)   | 0: Passed    | 1: Failed      |
| SR[2-4] | Not Used                               |  |              |                |
| SR[5]   | Ready / Busy<br>(For P/E/R Controller) | Cache Program/Cache Read operation, other Page Program/Block Erase/Read are same as IO6 (Note 1) | 0: Busy      | 1: Ready       |
| SR[6]   | Ready / Busy                           | Page Program, Block Erase, Cache Program, Read, Cache Read (Note 2)                              | 0: Busy      | 1: Ready       |
| SR[7]   | Write Protect                          | Page Program, Block Erase, Cache Program, Read   | 0: Protected | 1: Unprotected |

**Notes:**

1. During the actual programming operation, the SR[5] is "0" value; however, when the internal operation is completed during the cache mode, the SR[5] returns to "1".
2. The SR[6] returns to "1" when the internal cache is available to receive new data. The SR[6] value is consistent with the R/B#.

The following is an example of a HEX data bit assignment:

**Figure 18. Bit Assignment (HEX Data)**

**Figure 19. AC Waveforms for Status Read Operation**

## 6-10. Status Enhance Read

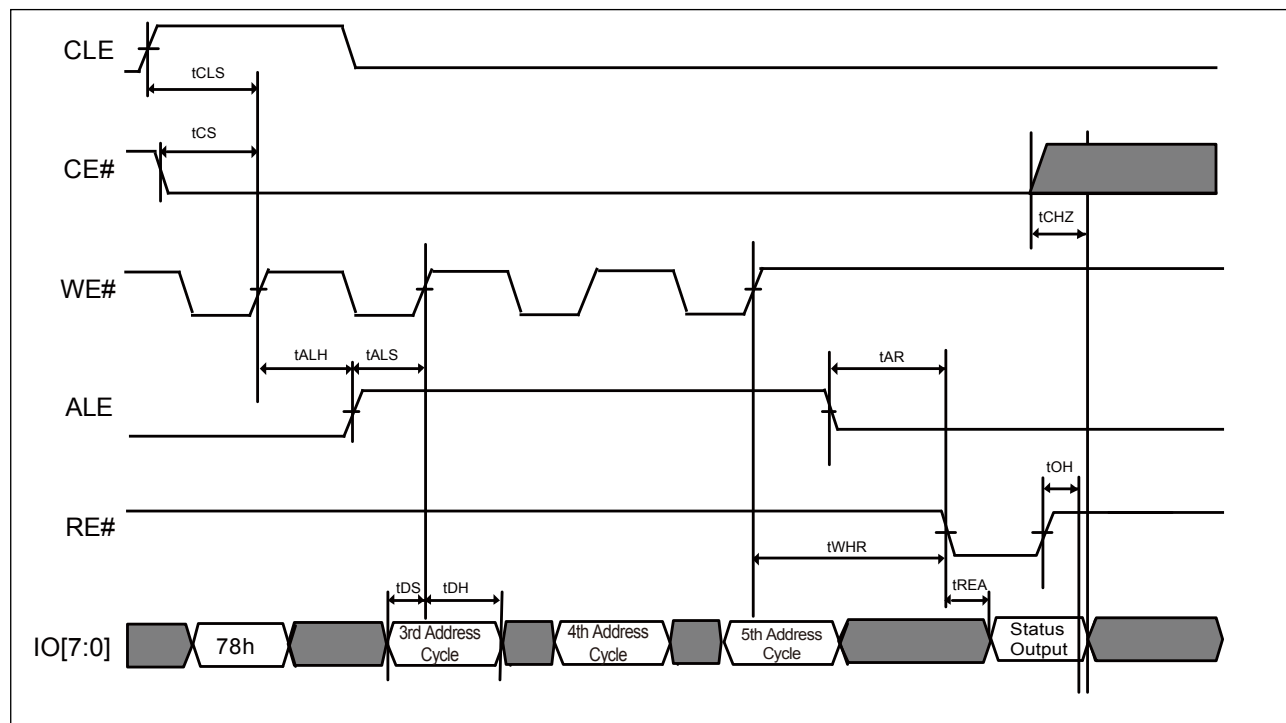

The 8Gb support the two-plane operation, the Status Enhanced Read command (78h) offers the alternative method besides the Status Read command to get the status of specific plane in the same NAND Flash device. The 8Gb has two dies in a package. The status enhance read command (78h) may output the status of ready/busy of selected die.

The SR[6] and SR[5] bits are shared with all planes of the selected die. However, the SR[0], SR[1], SR[3], SR[4] are for the status of specific plane in the row address. The Status Enhanced Read command is not allowed at power-on Reset (FFh) command, OTP enabled operation.

The selected die will stay in the status enhanced read mode until another valid command issuing. The non-addressed die which is remaining disselected to avoid the data-bus contention.

The Status Enhance Read command also can be used for selected die data output. After writing the 78h command followed by the three address cycles, the status of the selected die is output, after the selected die is ready, writing the read mode command (00h) and then it begins data-out.

**Figure 20. AC Waveforms for Status Enhance Operation**

## 6-11. Reset

The reset command FFh resets the read/program/erase operation and clear the status register to be E0h (when WP# is high). The reset command during the program/erase operation will result in the content of the selected locations (perform programming/erasing) might be partially programmed/erased.

If the Flash memory has already been set to reset stage with reset command, the additional new reset command is invalid.

**Figure 21. AC waveforms for Reset Operation**

## 6-12. Parameter Page Read (ONFI)

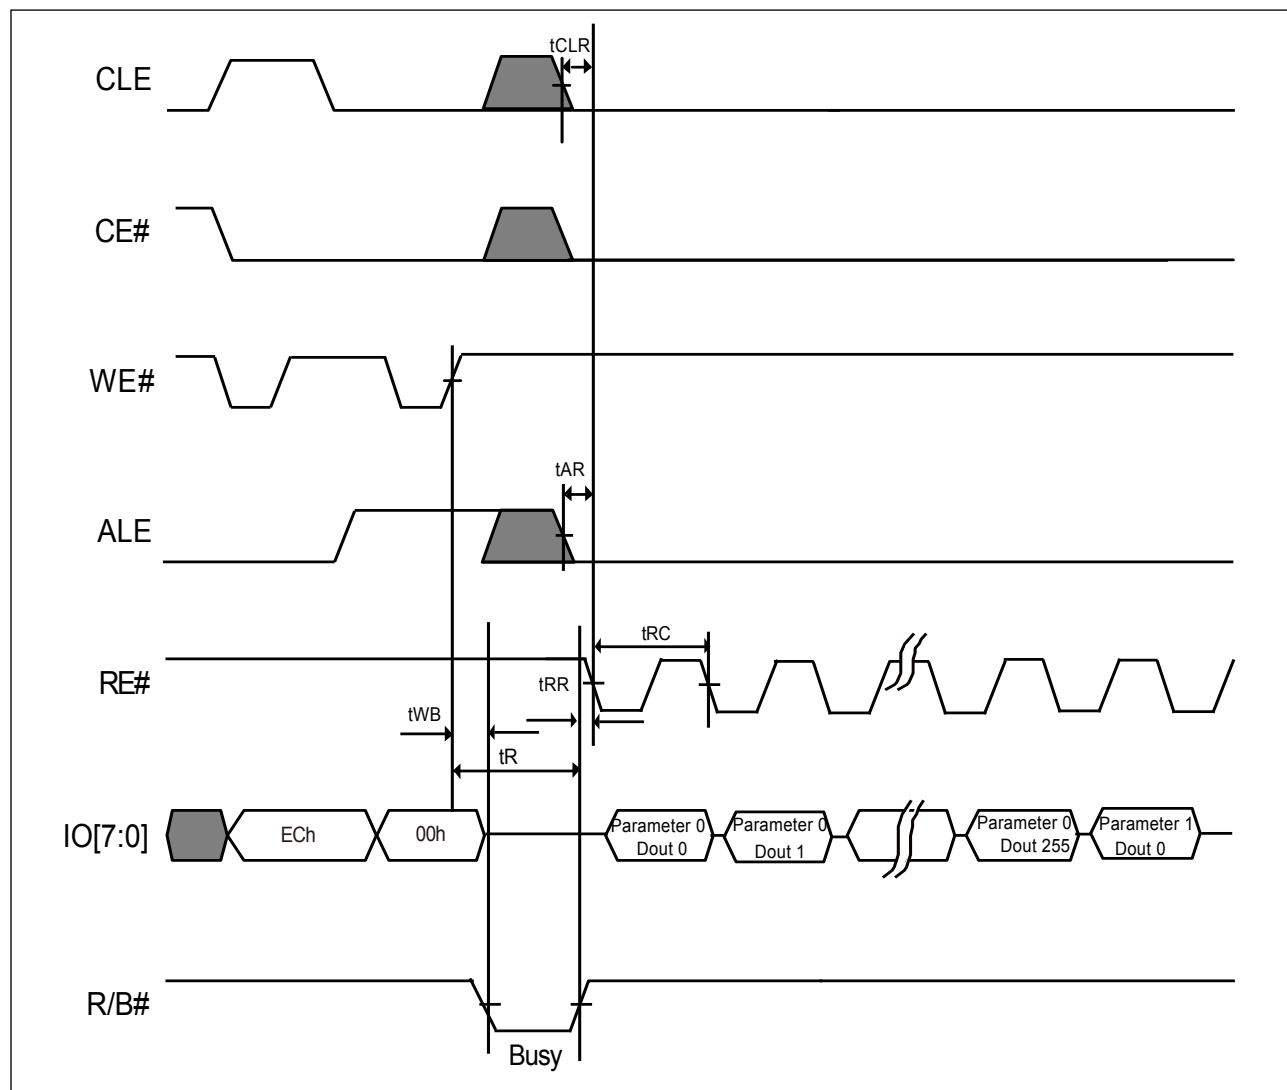

The NAND Flash device support ONFI Parameter Page Read and the parameter can be read out by sending the command of ECh and giving the address 00h. This command is valid only when internal all die are ready. The NAND device information may refer to the table of parameter page (ONFI), there are three copies of 256-byte data and additional redundant parameter pages.

Once sending the ECh command, the NAND device will remain in the Parameter Page Read mode until next valid command is sent.

The Random Data Out command set (05h-E0h) can be used to change the parameter location for the specific parameter data random read out.

The Status Read command (70h) can be used to check the completion with a following read command (00h) to enable the data out.

**Figure 22. AC waveforms for Parameter Page Read (ONFI) Operation**

**Figure 23. AC Waveforms for Parameter Page Read (ONFI) Random Operation (For 05h-E0h)**

**Table 5. Parameter Page (ONFI)**

| 166-253                     | Vendor Specific                               |           | 00h                         |
| 254-255                     | Integrity CRC                                 |           | Set at Test ( <b>Note</b> ) |
| Redundant Parameter Pages   |   |           |                             |
| Byte#                       | Description                                   |           | Data                        |
| 256-511                     | Value of Bytes 0-255                          |           |                             |
| 512-767                     | Value of Bytes 0-255                          |           |                             |
| 768+                        | Additional Redundant Parameter Pages          |           |                             |

**Note:** The Integrity CRC (Cycling Redundancy Check) field is used to verify that the contents of the parameters page were transferred correctly to the host. Please refer to ONFI 1.0 specifications for details.

The CRC shall be calculated using the following 16-bit generator polynomial:

$$G(X) = X^{16} + X^{15} + X^2 + 1$$

## 6-13. Unique ID Read (ONFI)

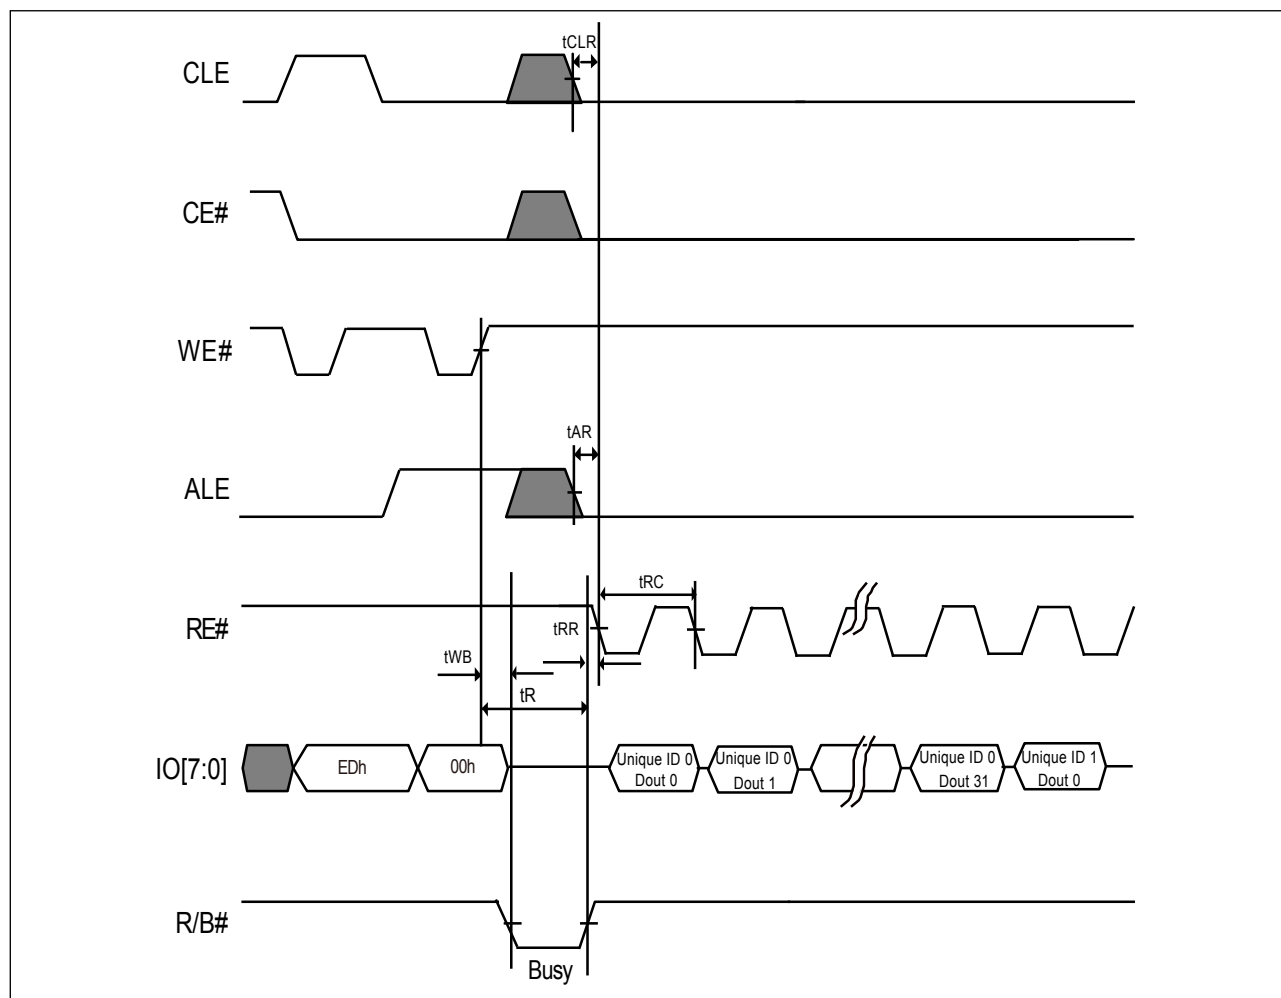

The unique ID is 32-byte and with 16 copies for back-up purpose. After writing the Unique ID read command (EDh) and following the one address byte (00h), the host may read out the unique ID data. The host need to XOR the 1st 16-byte unique data and the 2nd 16-byte complement data to get the result, if the result is FFh, the unique ID data is correct; otherwise, host need to repeat the XOR with the next copy of Unique ID data.

Once sending the EDh command, the NAND device will remain in the Unique ID read mode until next valid command is sent. This command is valid only when internal all die are ready.

To change the data output location, it is recommended to use the Random Data Out command set (05h-E0h).

The Status Read command (70h) can be used to check the completion. To continue the read operation, a following read command (00h) to re-enable the data out is necessary.

**Figure 24. AC waveforms for Unique ID Read Operation**

**Figure 25. AC waveforms for Unique ID Read Operation (For 05h-E0h)**

## 6-14. Feature Set Operation (ONFI)

The Feature Set operation is to change the default power-on feature sets by using the Set Feature and Get Feature command and writing the specific parameter data (P1-P4) on the specific feature addresses. The NAND device may remain the current feature set until next power cycle since the feature set data is volatile. However, the reset command (FFh) can not reset the current feature set.

**Table 6-1. Definition of Feature Address**

| Feature Address   | Description          |
|-------------------|----------------------|
| 00h-8Fh, 91h-FFh, | Reserved             |
| 90h               | Array Operation Mode |

**Table 6-2. Sub-Feature Parameter Table of Feature Address - 90h (Array Operation Mode)**

| Sub Feature Parameter | Definition           |                | IO7          | IO6 | IO5 | IO4 | IO3 | IO2 | IO1 | IO0 | Values     | Notes |
|-----------------------|----------------------|----------------|--------------|-----|-----|-----|-----|-----|-----|-----|------------|-------|
| P1                    | Array Operation Mode | Normal         | Reserved (0) |     |     |     |     |     | 0   | 0   | 0000 0000b | 1     |
|                       |                      | OTP Operation  | Reserved (0) |     |     | x   | 0   | 0   | 1   |     | 0000 x001b |       |
|                       |                      | OTP Protection | Reserved (0) |     |     | x   | 0   | 1   | 1   |     | 0000 x011b |       |
| P2                    |                      |                | Reserved (0) |     |     |     |     |     |     |     | 0000 0000b |       |
| P3                    |                      |                | Reserved (0) |     |     |     |     |     |     |     | 0000 0000b |       |
| P4                    |                      |                | Reserved (0) |     |     |     |     |     |     |     | 0000 0000b |       |

**Note 1.** The value is clear to 00h at power cycle.

### 6-14-1. Set Feature (ONFI)

The Set Feature command is to change the power-on default feature set. After sending the Set Feature command (EFh) and following specific feature and then input the P1-P4 parameter data to change the default power-on feature set. Once sending the EFh command, the NAND device will remain in the Set Feature mode until next valid command is sent. This command is valid only when internal all die are ready.

The Status Read command (70h) may check the completion of the Set Feature.

**Figure 26. AC Waveforms for Set Feature (ONFI) Operation**

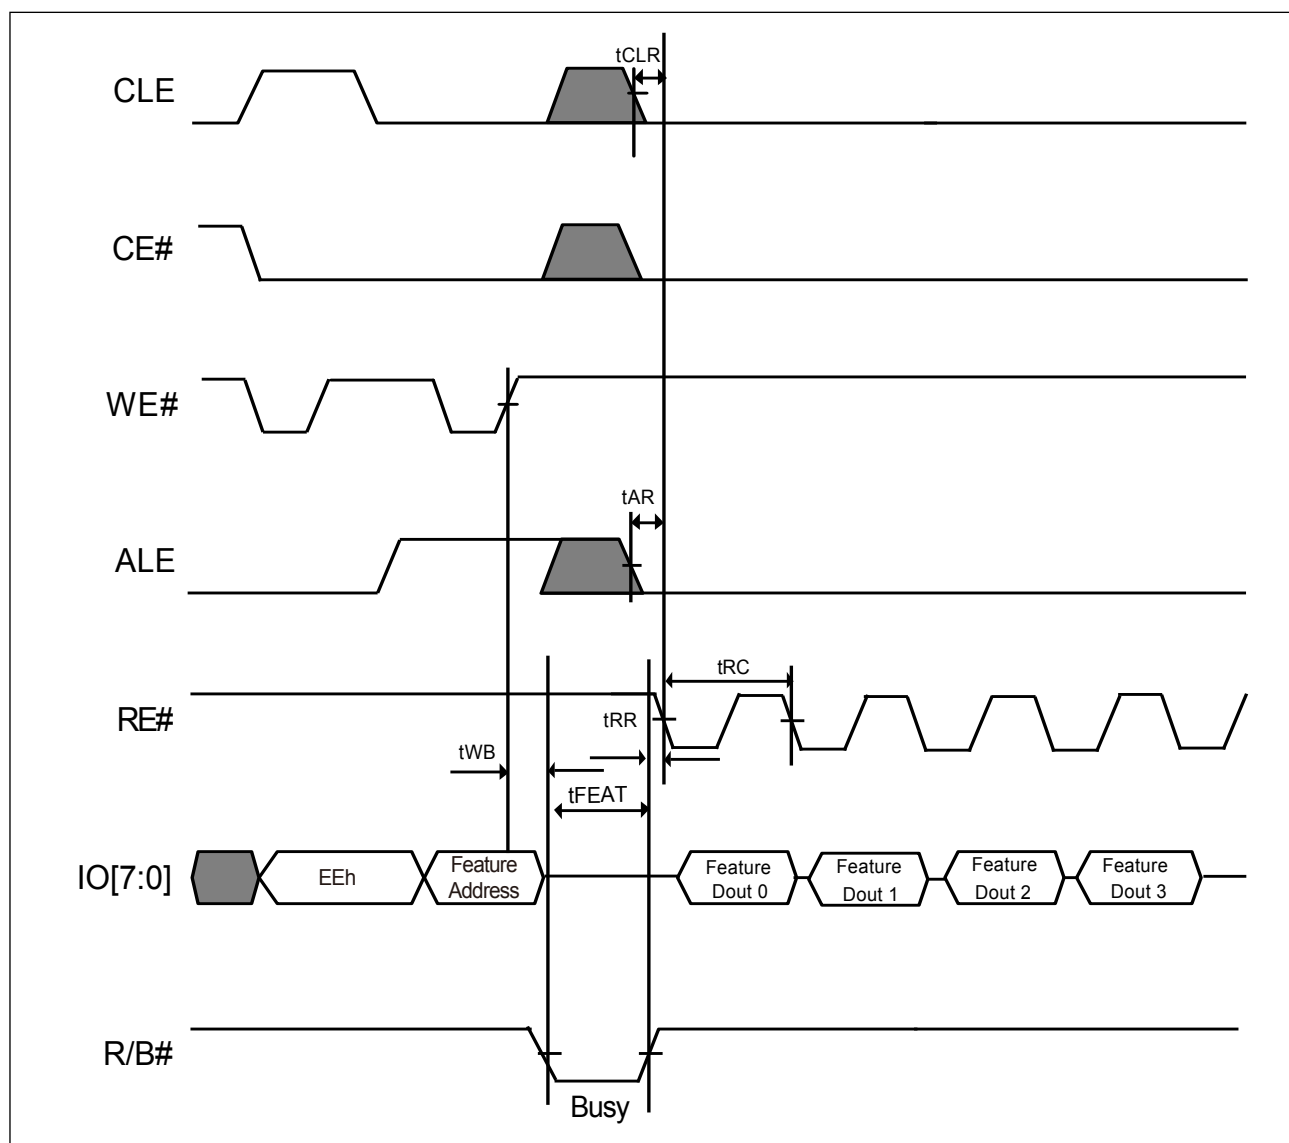

## 6-14-2. Get Feature (ONFI)

The Get Feature command is to read sub-feature parameter. After sending the Get Feature command (EEh) and following specific feature, the host may read out the P1-P4 sub- feature parameter data. Once sending the EEh command, the NAND device will remain in the Get Feature mode until next valid command is sent. This command is valid only when internal all die are ready.

The Status Read command (70h) can be used to check the completion. To continue the read operation, a following read command (00h) to re-enable the data out is necessary.

Please refer to the following waveform of **Get Feature Operation** for details.

**Figure 27. AC Waveforms for Get Feature (ONFI) Operation**

### 6-14-3. Secure OTP (One-Time-Programmable) Feature

There is an OTP area which has thirty full pages (30 x 2,112-byte) guarantee to be good for system device serial number storage or other fixed code storage. The OTP area is a non-erasable and one-time-programmable area, which is default to "1" and allows whole page or partial page program to be "0", once the OTP protection mode is set, the OTP area becomes read-only and cannot be programmed again.

The OTP operation is operated by the Set Feature/ Get Feature operation to access the OTP operation mode and OTP protection mode.

To check the NAND device is ready or busy in the OTP operation mode, either checking the R/B# or writing the Status Read command (70h) may collect the status.

To exit the OTP operation or protect mode, it can be done by writing 00h to P1 at feature address 90h.

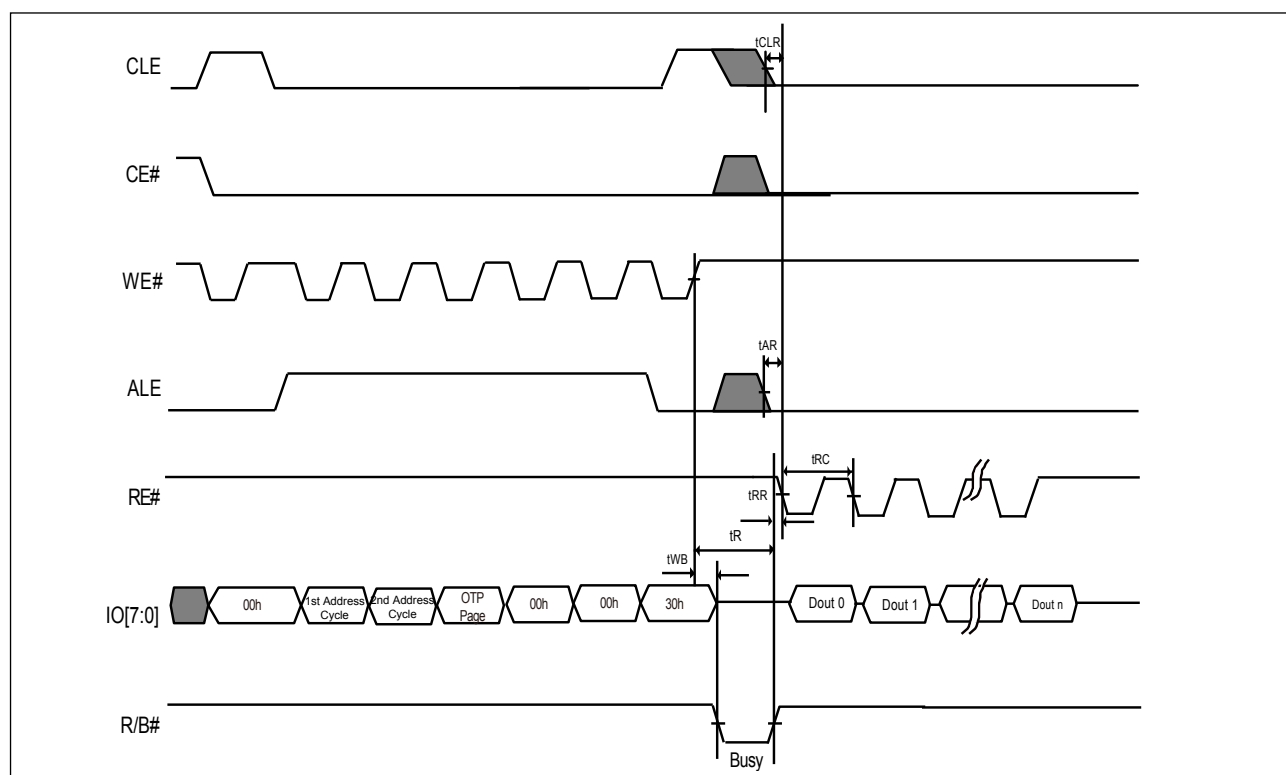

#### OTP Read/Program Operation

To enter the OTP operation mode, it is by using the Set Feature command (EFh) and followed by the feature address (90h) and then input the 01h to P1 and 00h to P2-P4 of sub-Feature Parameter data( please refer to the sub-Feature Parameter table). After enter the OTP operation mode, the normal Read command (00h-30h) or Page program( 80h-10h) command can be used to read the OTP area or program it. The address of OTP is located on the 02h-1Fh of page address.

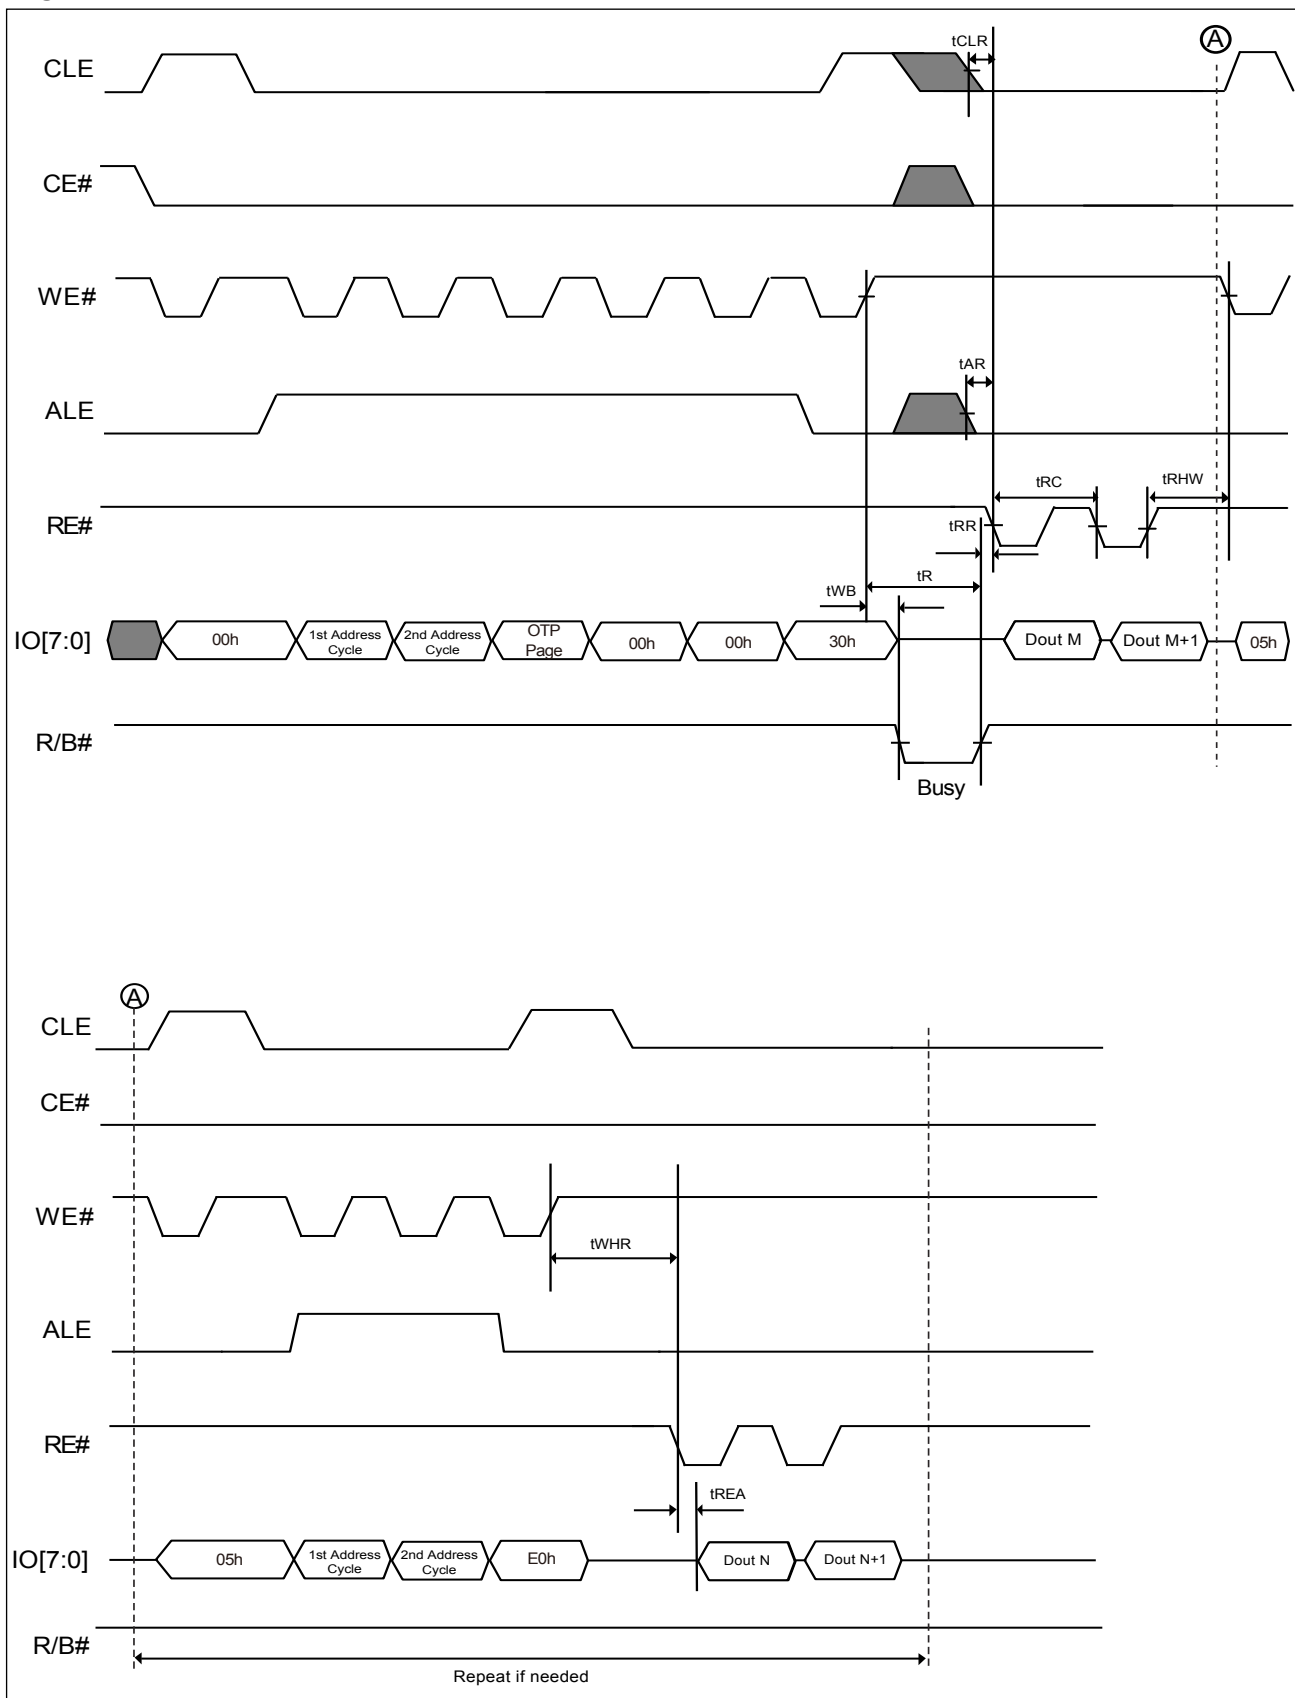

Besides the normal Read command, the Random Data Output command (05h-E0h) can be used for read OTP data. However, the Cache Read command is not supported in the OTP area.

Besides the normal page program command, the Random Data Input command (85h) allows multi-data load in non-sequential address. After data load is completed, a program confirm command (10h) is issued to start the page program operation. The number of partial-page OTP program is 8 per each OTP page.

**Figure 28. AC Waveforms for OTP Data Read**

**Figure 29. AC Waveforms for OTP Data Read with Random Data Output**

**Figure 30. AC Waveforms for OTP Data Program**

**Figure 31. AC Waveforms for OTP Data Program with Random Data Input**

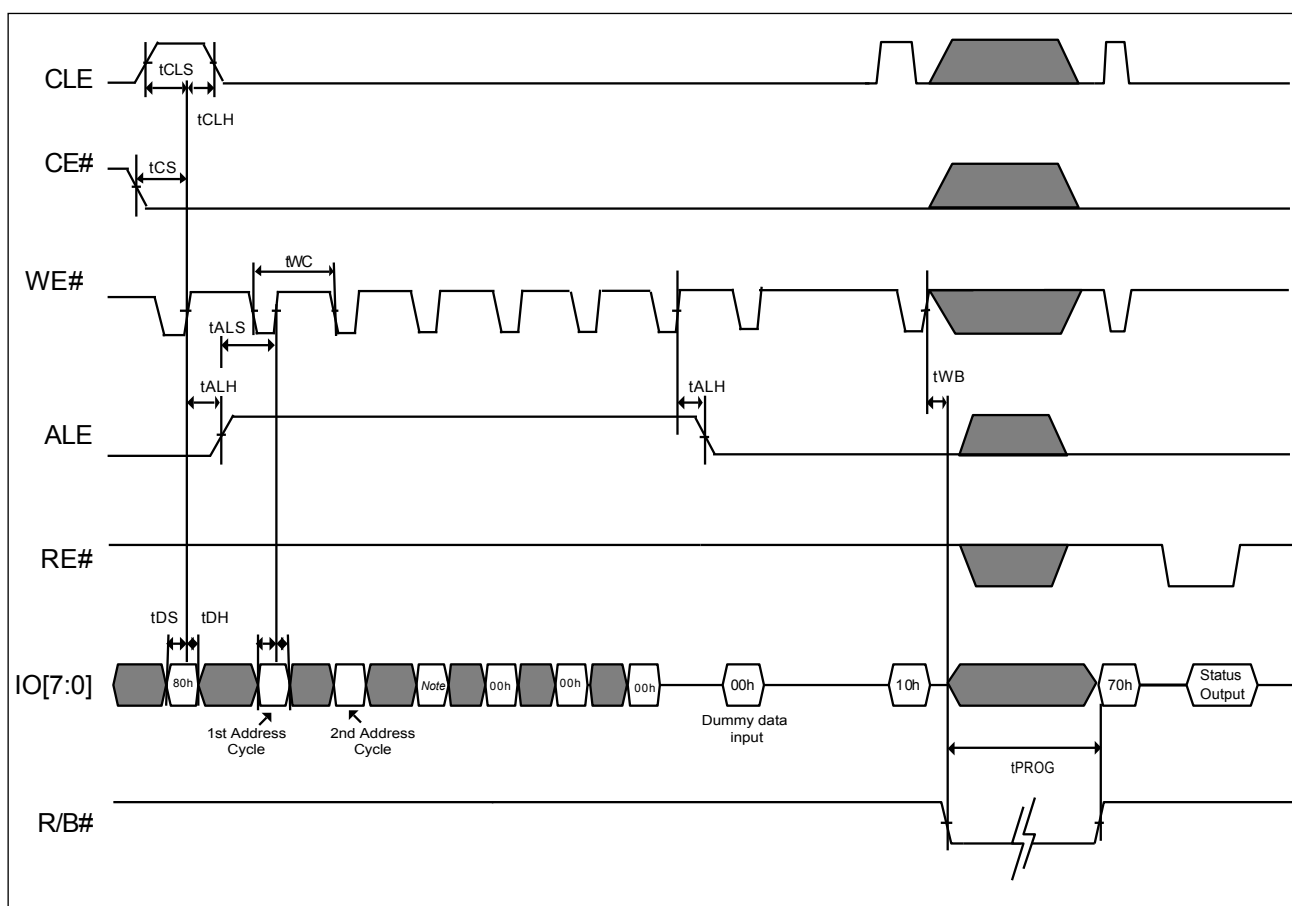

## OTP Protection Operation

To prevent the further OTP data to be changed, the OTP protection mode operation is necessary. To enter the OTP protection mode, it can be done by using the Set Feature command (EFh) and followed by the feature address (90h) and then input the 03h to P1 and 00h to P2-P4 of sub-Feature Parameter data (please refer to the sub-Feature Parameter table). And then the normal page program command (80h-10h) with the address 00h before the 10h command is required.

The OTP Protection mode is operated by the whole OTP area instead of individual OTP page. Once the OTP protection mode is set, the OTP area cannot be programmed or unprotected again.

**Figure 32. AC Waveforms for OTP Protection Operation**

**Note:** This address cycle can be any value since the OTP protection protects the entire OTP area instead of individual OTP page.

## 6-15. Two-Plane Operations

The 8Gb NAND device is divided into two planes in each die for performance improvement. In the two-plane operation, the NAND device may proceed the same type operation (for example: Program or Erase) on the two planes of a die concurrent or overlapped by the two-plane command sets. The different type operations cannot be done in the two-plane operations; for example, it cannot be done to erase one plane and program the other plane concurrently. The two-plane operations should be in the same die.

The plane address A18 must be different from each selected plane address. The page address A12-A17 of individual plane must be the same for two-plane operation.

The Status Read command( 70h) may check the device status in the two-plane operation, if the result is failed and then the Status Enhanced Read (78h) may check which plane is failed.

## 6-16. Two-plane Program (ONFI) and Two-plane Cache Program (ONFI)

The two-plane program command (80h-11h) may input data to cache buffer and wait for the final plane data input with command (80h-10h) and then transfer all data to NAND array. As for the two-plane cache program operation, it can be achieved by a two-plane program command (80h-11h) with a cache program command (80h-15h), and the final address input with the confirm command (80h-10h). Please refer to the waveforms of two-plane program and two-plane cache program for details. The random data input command (85h) can be also used in the two-plane program operation for changing the column address, please refer to the waveform of two-plane program with random data input.

### Notes:

1. Page number should be the same for both planes.
2. Block address [29:18] can be different, A30 should be the same for both planes.

For examples:

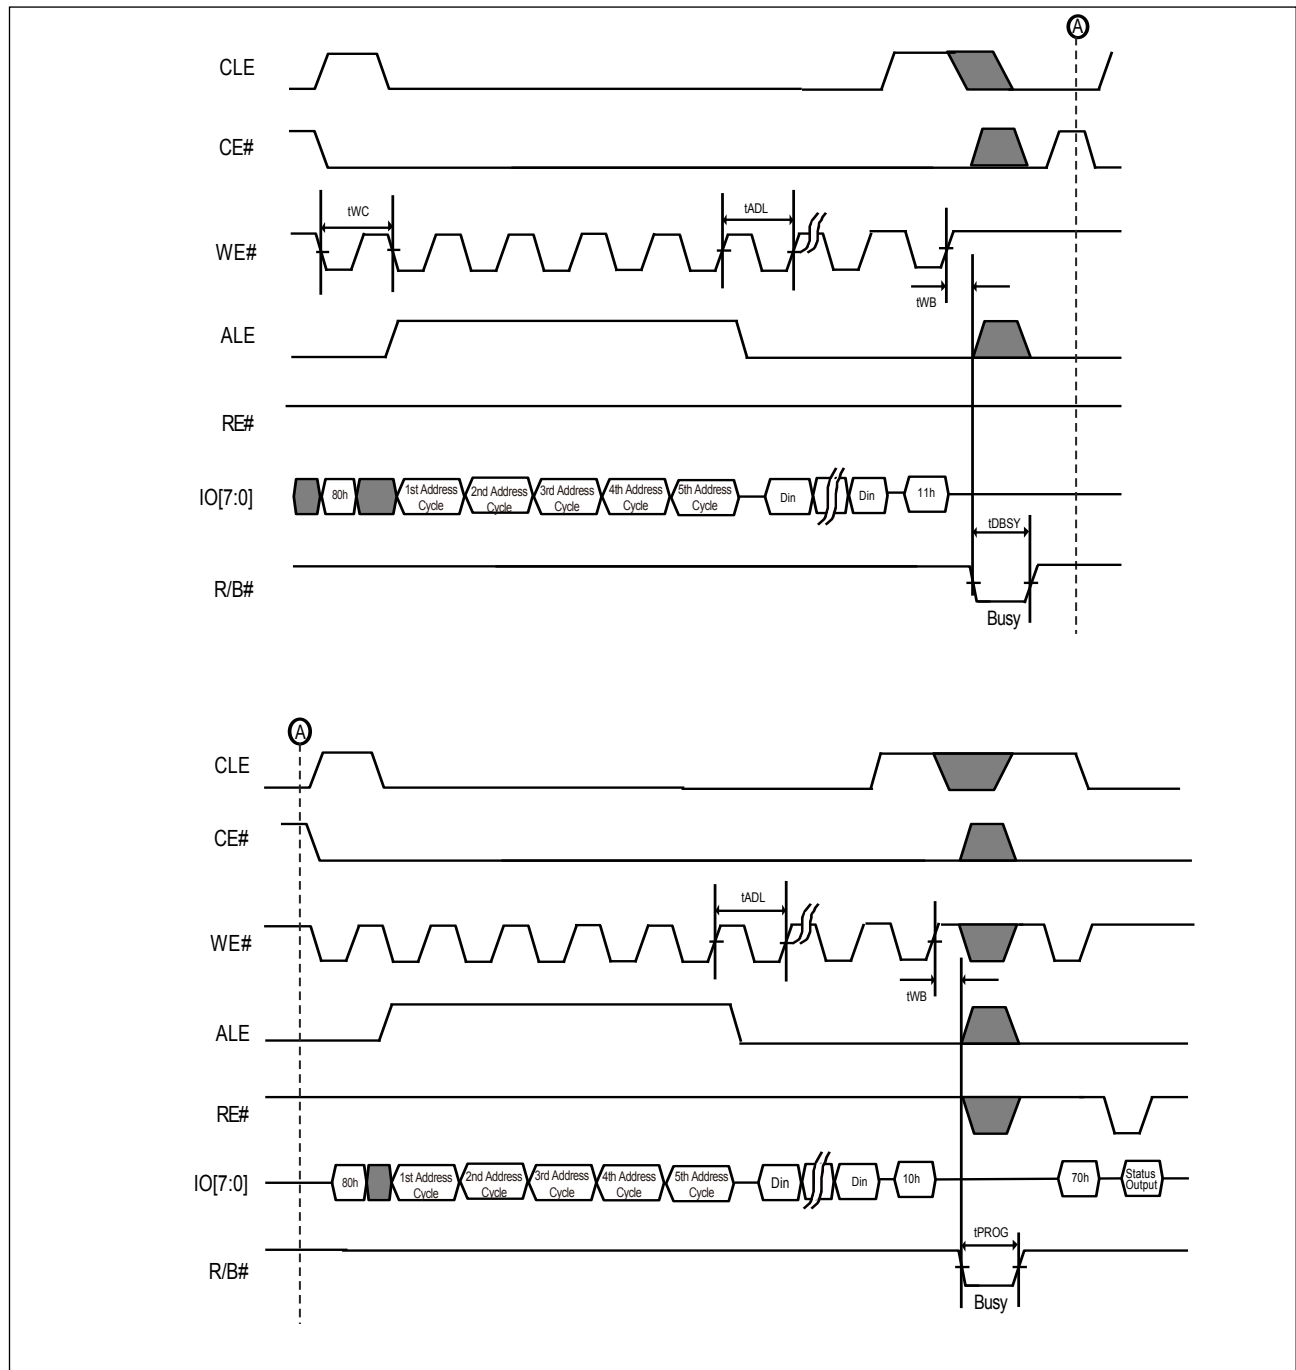

*If the user issues 80h-(block address 5h, page address 5h) -11h - 80h -  
(block address - 18h, page address 5h) - 10h,*

*The programmed page is*

- Plane 0: block address 18h, page address 5h
- Plane 1: block address 5h, page address 5h

**Note:** Die selection address = A30, Block address = A [29:18], Page address = A [17:12]

**Figure 33-1. AC Waveforms for Two-plane Program (ONFI)**

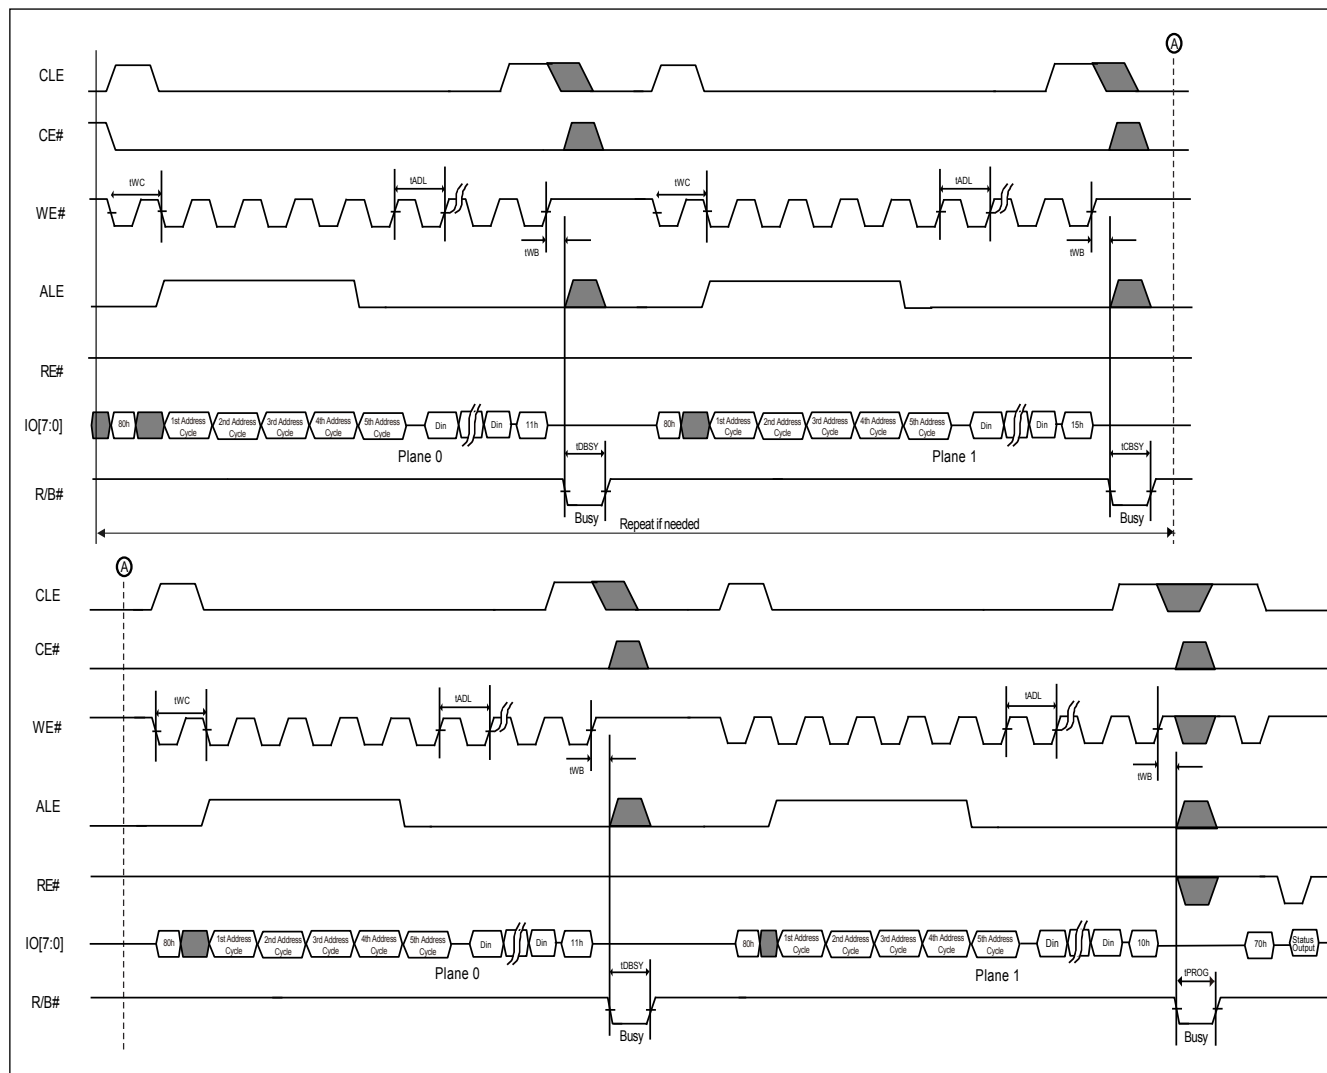

**Figure 33-2. AC Waveforms for Page Program Random Data Two-plane (ONFI)**

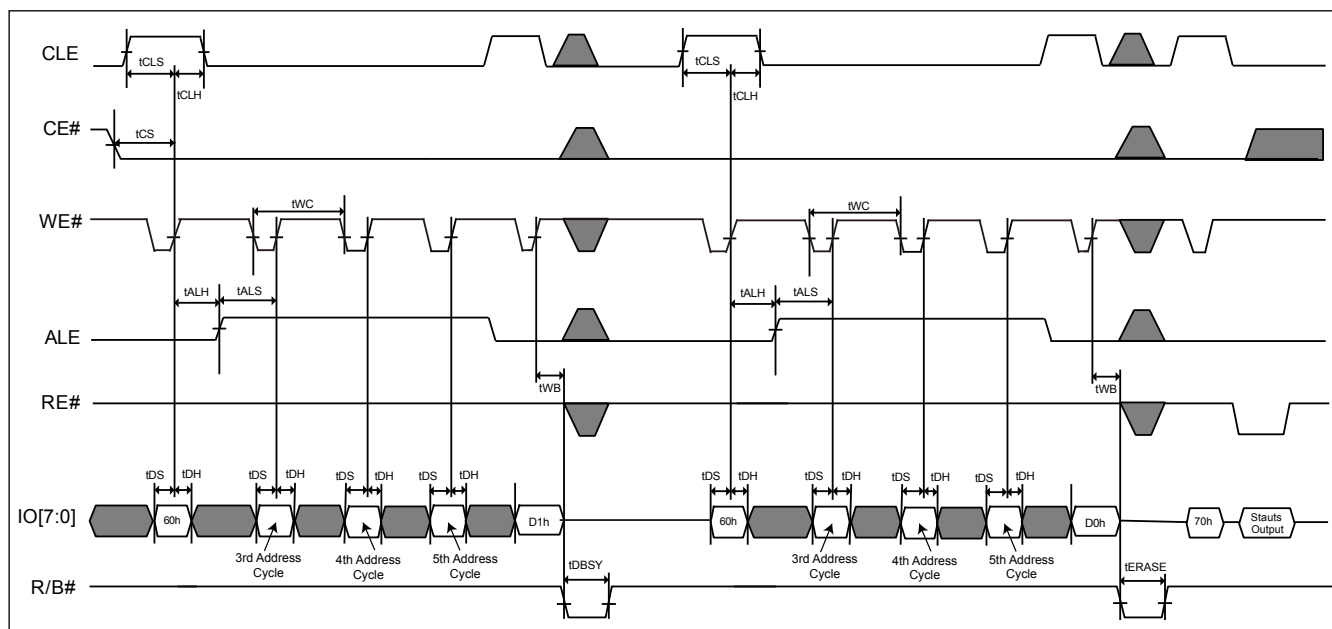

**Figure 34. AC Waveforms for Two-plane Cache Program (ONFI)**

## 6-17. Two-plane Block Erase (ONFI)

The two-plane erase command (60h-D1h) may erase the selected blocks in parallel from each plane, with setting the 1st and 2nd block address by (60h-D1h) & (60h-D0h) command and then erase two selected blocks from NAND array. Please refer to the waveforms of two-plane erase for details.

**Figure 35. AC Waveforms for Two-plane Erase (ONFI)**

## 6-18. Interleaved Die Operations

The interleaved Die Operation can be applied on an idle die while another die is busy. The interleaved Die Operations are allowed on the following commands: Read Mode, Page Program, Two planes Page Program, Cache Program, Two Planes Cache Program, Block Erase and Two planes Block Erase. For the interleaved Die operations with Two planes page program, Two planes cache program and Two planes block erase, the die address (A30) should be the same.

A series program operation must be applied before a series read operation while a interleaved die operation involves a series read operation and a series program operation. To avoid the cache register data be cleared out by 80h command, the data of read operation must be sent to host before the next program operation applies.

To check the operation status during the Interleaved Die Operations, a data polling of R/B# may determine the operation completion of all dies. The R/B# signal is 0, which means any die is busy; R/B# signal is 1, which means all dies are ready. The other way to check the operation completion is to send Status Enhance Read command (78h) to select die for individual die status. Please note the Status Read command (70h) must not be applied for the status check during the Interleaved Die Operation. It will cause data-bus contention.

As for the cache operation during the Interleaved Die Operation, the status bit SR[6] returns to "1" when the internal cache is available to receive new data. When all operations are completed on a die, the SR[5] shows "1".

The Interleaved Die Operations cannot be applied after the following command: RESET (FFh), ID read (90h), Parameter Page Read (ECh), Unique ID Read (EDh), Set Feature (EFh), Get Feature (EEh). After the the SR[5] shows "1" ready, and then the Interleaved Die Operation may be applied.

## 7. PARAMETERS

### 7-1. ABSOLUTE MAXIMUM RATINGS

|  |                 |
|--|-----------------|
| Temperature under Bias                             | -50°C to +125°C |
| Storage temperature                                | -65°C to +150°C |
| All input voltages with respect to ground (Note 2) | -0.6V to 4.6V   |
| VCC supply voltage with respect to ground (Note 2) | -0.6V to 4.6V   |
| ESD protection                                     | >2000V          |

**Notes:**

1. The reliability of device may be impaired by exposing to extreme maximum rating conditions for long range of time.
2. Permanent damage may be caused by the stresses higher than the "Absolute Maximum Ratings" listed.
3. During voltage transitions, all pins may overshoot Vss to -2.0V and Vcc to +2.0V for periods up to 20ns, see the two waveforms as below.

**Figure 37. Maximum Negative Overshoot**

**Figure 38. Maximum Positive Overshoot**

**Table 7. Operating Range**

| Temperature    | VCC   | Tolerance  |
|----------------|-------|------------|
| -40°C to +85°C | +3.3V | 2.7 - 3.6V |

**Table 8. DC Characteristics**

| Symbol     | Parameter                                | Test Conditions                 | Min.     | Typical              | Max.      | Unit | Notes |
|------------|--|---------------------------------|----------|----------------------|-----------|------|-------|
| VIL        | Input low level                          |                                 | -0.3     |                      | 0.2VCC    | V    |       |
| VIH        | Input high level                         |                                 | 0.8VCC   |                      | VCC + 0.3 | V    |       |
| VOL        | Output low voltage                       | IOL = 2.1mA, VCC = VCC Min.     |          |                      | 0.2       | V    |       |
| VOH        | Output high voltage                      | IOH = -400uA, VCC = VCC Min.    | VCC-0.2V |                      |           | V    |       |

| tRST   | Device reset time (Idle/ Read/ Program/ Erase)                      |      |      | 5/5/10/500 | us   | 1    |

**Note 1.** ONFI Mode 5 compliant

## 8. OPERATION MODES: LOGIC AND COMMAND TABLES

Address input, command input and data input/output are managed by the CLE, ALE, CE#, WE#, RE# and WP# signals, as shown in **Table 13. Logic Table** below.

Program, Erase, Read and Reset are four major operations modes controlled by command sets, please refer to **Table 14-1** and **14-2**.

**Table 13. Logic Table**

| Mode                       | CE# | RE#   | WE#   | CLE | ALE | WP#    |
|----------------------------|-----|---|---|-----|-----|--------|
| Address Input (Read Mode)  | L   | H   |  | L   | H   | X      |
| Address Input (Write Mode) | L   | H   |  | L   | H   | H      |
| Command Input (Read Mode)  | L   | H   |  | H   | L   | X      |
| Command Input (Write Mode) | L   | H   |  | H   | L   | H      |
| Data Input                 | L   | H   |  | L   | L   | H      |
| Data Output                | L   |  | H   | L   | L   | X      |
| During Read (Busy)         | X   | H   | H   | L   | L   | X      |
| During Programming (Busy)  | X   | X   | X   | X   | X   | H      |
| During Erasing (Busy)      | X   | X   | X   | X   | X   | H      |
| Program/Erase Inhibit      | X   | X   | X   | X   | X   | L      |
| Stand-by                   | H   | X   | X   | X   | X   | 0V/VCC |

**Notes:**

1. H = VIH; L = VIL; X = VIH or VIL
2. WP# should be biased to CMOS high or CMOS low for stand-by.

**Table 14-1. HEX Command Table**

|                             | First Cycle | Second Cycle | Acceptable While Busy |
|-----------------------------|-------------|--------------|-----------------------|
| Read Mode                   | 00H         | 30H          |                       |
| Random Data Input           | 85H         | -            |                       |
| Random Data Output          | 05H         | E0H          |                       |
| Cache Read Random           | 00H         | 31H          |                       |
| Cache Read Sequential       | 31H         | -            |                       |
| Cache Read End              | 3FH         | -            |                       |
| ID Read                     | 90H         | -            |                       |
| Parameter Page Read (ONFI)  | ECH         | -            |                       |
| Unique ID Read (ONFI)       | EDH         | -            |                       |
| Set Feature (ONFI)          | EFH         | -            |                       |
| Get Feature (ONFI)          | EEH         | -            |                       |
| Reset                       | FFH         | -            | V                     |
| Page Program                | 80H         | 10H          |                       |
| Cache Program               | 80H         | 15H          |                       |
| Block Erase                 | 60H         | D0H          |                       |
| Status Read                 | 70H         | -            | V                     |
| Status Enhanced Read (ONFI) | 78H         | -            | V                     |

**Table 14-2. Two-plane Command Set**

|                                | First Cycle | Second Cycle | Third Cycle | Fourth Cycle |
|--------------------------------|-------------|--------------|-------------|--------------|
| Two-plane Program (ONFI)       | 80H         | 11H          | 80H         | 10H          |
| Two-plane Cache Program (ONFI) | 80H         | 11H          | 80H         | 15H          |
| Two-plane Block Erase (ONFI)   | 60H         | D1H          | 60H         | D0H          |

**Caution:** None of the undefined command inputs can be accepted except for the command set in the above table.

## 8-1. R/B#: Termination for The Ready/Busy# Pin (R/B#)

The R/B# is an open-drain output pin and a pull-up resistor is necessary to add on the R/B# pin. The R/B# outputs the ready/busy status of read/program/ erase operation of the device. When the R/B# is at low, the device is busy for read or program or erase operation. When the R/B# is at high, the read/program/erase operation is finished.

### Rp Value Guidance

The rise time of the R/B# signal depends on the combination of Rp and capacitive loading of the R/B# circuit. It is approximately two times constants (Tc) between the 10% and 90% points on the R/B# waveform.

$$T_c = R \times C$$

Where R = Rp (Resistance of pull-up resistor), and C = CL (Total capacitive load)

The fall time of the R/B# signal majorly depends on the output impedance of the R/B# signal and the total load capacitance.

$$R_p (\text{Min.}) = \frac{V_{cc} (\text{Max.}) - V_{OL} (\text{Max.})}{I_{OL} + \Sigma I_L}$$

#### Notes:

1. Considering of the variation of device-by-device, the above data is for reference to decide the resistor value.
2. Rp maximum value depends on the maximum permissible limit of tr.
3. IL is the total sum of the input currents of all devices tied to the R/B pin.

**Figure 39. R/B# Pin Timing Information**

## 8-2. Power On/Off Sequence

After the Chip reaches the power on level ( $V_{th} = V_{cc \text{ min.}}$ ), the internal power on reset sequence will be triggered. During the internal power on reset period, no any external command is accepted. There are two ways to identify the termination of the internal power on reset sequence. Please refer to **Figure 40. Power On/Off Sequence**.

- R/B# pin
- Wait 1 ms

During the power on and power off sequence, it is recommended to keep the WP# = Low for internal data protection.

**Figure 40. Power On/Off Sequence**

### 8-2-1. WP# Signal

WP# going Low can cause program and erase operations automatically reset.

The enabling & disabling of the both operations are as below:

**Figure 41-1. Enable Programming of WP# Signal**

**Figure 41-2. Disable Programming of WP# Signal**

**Figure 41-3. Enable Erasing of WP# Signal**

**Figure 41-4. Disable Erasing of WP# Signal**

## 9. SOFTWARE ALGORITHM

### 9-1. Invalid Blocks (Bad Blocks)

The bad blocks are included in the device while it gets shipped. During the time of using the device, the additional bad blocks might be increasing; therefore, it is recommended to check the bad block marks and avoid using the bad blocks. Furthermore, please read out the bad block information before any erase operation since it may be cleared by any erase operation.

**Figure 42. Bad Blocks**

While the device is shipped, the value of all data bytes of the good blocks are FFh. The 1st byte of the 1st and 2nd page in the spare area for bad block will be 00h. The erase operation at the bad blocks is not recommended.

After the device is installed in the system, the bad block checking is recommended. The figure shows the brief test flow by the system software managing the bad blocks while the bad blocks were found. When a block gets damaged, it should not be used any more.

Due to the blocks are isolated from bit-line by the selected gate, the performance of good blocks will not be impacted by bad ones.

**Table 15. Valid Blocks**

|                              | Density | Min. | Typ. | Max. | Unit  | Remark                                       |
|------------------------------|---------|------|------|------|-------|--|
| Valid (Good)<br>Block Number | 8Gb     | 8032 |      | 8192 | Block | Block 0 is guaranteed to be good (with ECC). |

**Note:** the 8Gb consists of two 4Gb dies, each die has minimum 4016 valid blocks.

## 9-2. Bad Block Test Flow

Although the initial bad blocks are marked by the flash vendor, they could be inadvertently erased and destroyed by a user that does not pay attention to them. To prevent this from occurring, it is necessary to always know where any bad blocks are located. Continually checking for bad block markers during normal use would be very time consuming, so it is highly recommended to initially locate all bad blocks and build a bad block table and reference it during normal NAND flash use. This will prevent having the initial bad block markers erased by an unexpected program or erase operation. Failure to keep track of bad blocks can be fatal for the application. For example, if boot code is programmed into a bad block, a boot up failure may occur. The following section shows the recommended flow for creating a bad block table.

**Figure 43. Bad Block Test Flow**

**Note:** Read 00h check is at the 1st byte of the 1st and 2nd pages of the block spare area.

## 9-3. Failure Phenomena for Read/Program/Erase Operations

The device may fail during a Read, Program or Erase operation. The following possible failure modes should be considered when implementing a highly reliable system:

**Table 16. Failure Modes**

| Failure Mode               | Detection and Countermeasure | Sequence          |
|----------------------------|------------------------------|-------------------|
| <b>Erase Failure</b>       | Status Read after Erase      | Block Replacement |
| <b>Programming Failure</b> | Status Read after Program    | Block Replacement |
| <b>Read Failure</b>        | Read Failure                 | ECC               |

## 9-4. Program

It is feasible to reprogram the data into another page (Page B) when an error occurred in Page A by loading from an external buffer. Then create a bad block table or by using another appropriate scheme to prevent further system accesses to Page A.

**Figure 44. Failure Modes**

**Figure 45. Program Flow Chart**

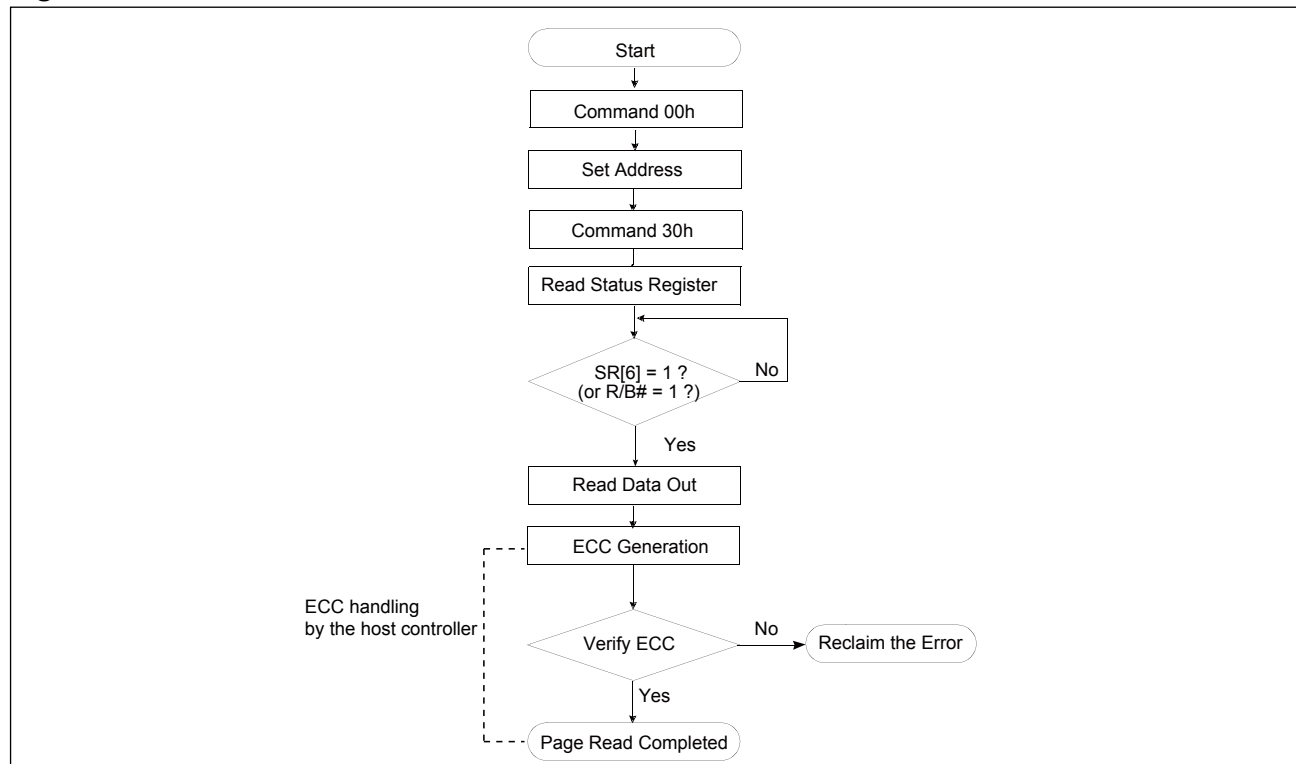

## 9-5. Erase

To prevent future accesses to this bad block, it is feasible to create a table within the system or by using another appropriate scheme when an error occurs in an Erase operation.

**Figure 46. Erase Flow Chart**

**Figure 47. Read Flow Chart**

## 10. PACKAGE INFORMATION

**Title:** Package Outline for TSOP(I) 48L (12X20mm)NORMAL FORM

## 11. REVISION HISTORY

| Rev. No. | Descriptions   | Page   | Date        |
|----------|--|--------|-------------|
| 0.01     | 1. Added interleaved operation waveforms   | P60-63 | JAN/14/2015 |
|          | 2. Corrected waveform of OTP protection tWB timing from WE# high to busy   | P54    |             |
|          | 3. Revised the bad block mark from non-FFh to 00h, also revised the page of bad block mark from 1st or 2nd page to 1st and 2nd page                                | P74-75 |             |
| 0.02     | 1. Changed title from "Advanced information" to "Preliminary"  | ALL    | FEB/02/2015 |
| 1.0      | 1. Removed "Preliminary" title   | ALL    | MAR/16/2015 |
| 1.1      | 1. Added a product statement for Ordering Information  | P9     | JAN/24/2017 |
|          | 2. Aligned the term of "plane 1" & "plane 2" as "plane 0" & "plane 1"  | P58    |             |
|          | 3. Added overshoot/undershoot waveforms  | P64    |             |
|          | 4. Added the tRST=5us for the device reset time from idle  | P67    |             |
|          | 5. Modifications of the power-on/off sequence: supplement the CE# signal, supplement the WE# single waveform with WE#=0 without toggle during the power-on period. | P71    |             |
