

## FEATURES

- 3 MHz switch mode charger
- 1.25 A charge current from dedicated charger
- Up to 680 mA charging current from 500 mA USB host
- Operating input voltage from 4.0 V up to 5.5 V
- Tolerant input voltage  $-0.5\text{ V}$  to  $+20\text{ V}$  (USB VBUS)
- Dead battery isolation FET between battery and charger output
- Battery thermistor input with automatic charger shutdown for when battery temperature exceeds limits
- Compliant with the JEITA Li-Ion battery charging temperature specification
- SYS\_EN\_OK flag to hold off system turn-on until battery is at minimum required level for guaranteed system startup due to minimum battery voltage and/or minimum battery charge level requirements
- EOC programming with C/20, C/10 and specific current level selection

## APPLICATIONS

- Digital still cameras
- Digital video cameras
- Single cell Li-Ion portable equipment
- PDA, audio, GPS devices
- Mobile phones

## GENERAL DESCRIPTION

The **ADP5065** charger is fully compliant with the USB 2.0, USB 3.0, and USB Battery Charging Specification 1.1 and enables charging via the mini USB VBUS pin from a wall charger, car charger, or USB host port.

The **ADP5065** operates from a 4 V to 5.5 V input voltage range but is tolerant of voltages of up to 20 V. This alleviates the concerns about the USB bus spiking during disconnect or connect scenarios.

The **ADP5065** also features an internal FET between the dc-to-dc charger output and the battery. This permits battery isolation and, hence, system powering under a dead battery or no battery scenario, which allows for immediate system function on connection to a USB power supply.

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

Based on the type of USB source, which is detected by an external USB detection chip, the **ADP5065** can be set to apply the correct current limit for optimal charging and USB compliance.

The **ADP5065** comes in a very small and low profile 20-lead WLCSP (0.5 mm pitch spacing) package.

The overall solution requires only five small, low profile external components consisting of four ceramic capacitors (one of which is the battery filter capacitor), one multilayer inductor. In addition to these components, there is one optional dead battery situation default setting resistor. This configuration enables a very small PCB area to provide an integrated and performance enhancing solution to USB battery charging and power rail provision.

Maximum Logic Low Input Voltage	V <sub>IL</sub>			0.5	V	
Minimum Logic High Input Voltage	V <sub>IH</sub>	1.2			V	
Pull-Down Resistance		215	350	610	kΩ	

<sup>1</sup> These values are programmable via I<sup>2</sup>C. Values are given with default register values.

<sup>2</sup> The output current during charging can be limited by  $I_{BUS}$  or by the isothermal charging mode.

<sup>3</sup> Programmable via external resistor programming, if required.

<sup>4</sup> JEITA can be enabled or disabled in I<sup>2</sup>C.

## RECOMMENDED INPUT AND OUTPUT CAPACITANCE

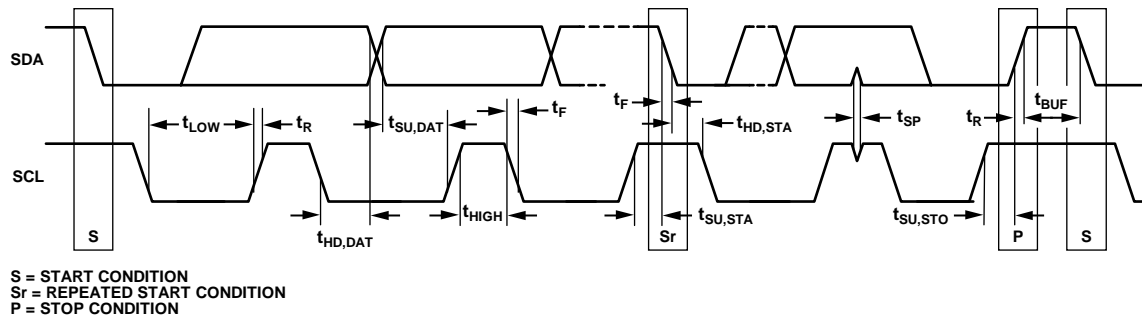

Table 2.

Parameter	Min	Typ	Max	Unit	Test Conditions/Comments
<b>CAPACITANCE</b>					
VINx Capacitance	1.0			$\mu\text{F}$	Effective capacitance
CFILT Pin Total External Capacitance	2.0	4.7	5.0	$\mu\text{F}$	Effective capacitance
ISO_Sx Pin Total Capacitance	10		50	$\mu\text{F}$	Effective capacitance
ISO_Bx Pin Total Capacitance	10			$\mu\text{F}$	Effective capacitance

**I<sup>2</sup>C-COMPATIBLE INTERFACE TIMING SPECIFICATIONS**

Table 3.

Parameter <sup>1</sup>	Symbol	Min	Typ	Max	Unit
<b>I<sup>2</sup>C-COMPATIBLE INTERFACE<sup>2</sup></b>					
Capacitive Load, Each Bus Line	$C_S$			400	pF
SCL Clock Frequency	$f_{SCL}$			400	kHz
SCL High Time	$t_{HIGH}$	0.6			$\mu$ s
SCL Low Time	$t_{LOW}$	1.3			$\mu$ s
Data Setup Time	$t_{SUDAT}$	100			ns
Data Hold Time	$t_{HDDAT}$	0		0.9	$\mu$ s
Setup Time for Repeated Start	$t_{SUSTA}$	0.6			$\mu$ s
Hold Time for Start/Repeated Start	$t_{HDSTA}$	0.6			$\mu$ s
Bus Free Time Between a Stop and a Start Condition	$t_{BUF}$	1.3			$\mu$ s
Setup Time for Stop Condition	$t_{SUSTO}$	0.6			$\mu$ s
Rise Time of SCL/SDA	$t_R$	20		300	ns
Fall Time of SCL/SDA	$t_F$	20		300	ns
Pulse Width of Suppressed Spike	$t_{SP}$	0		50	ns

<sup>1</sup> Guaranteed by design.<sup>2</sup> A master device must provide a hold time of at least 300 ns for the SDA signal to bridge the undefined region of the falling edge of SCL. See Figure 2, the I<sup>2</sup>C timing diagram.**Timing Diagram**Figure 2. I<sup>2</sup>C Timing Diagram

09370-002

**ABSOLUTE MAXIMUM RATINGS**

Table 4.

Parameter	Rating
VIN1, VIN2 to PGND1, PGND2	–0.5 V to +20 V
All Other Pins to AGND	–0.3 V to +6 V
Continuous Drain Current, Battery Supplementary Mode, from ISO_Bx to ISO_Sx	
$T_J \leq 85^\circ\text{C}$	2.2 A
$T_J = 125^\circ\text{C}$	1.1 A
Storage Temperature Range	–65°C to +150°C
Operating Junction Temperature Range	–40°C to +125°C
Soldering Conditions	JEDEC J-STD-020

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**THERMAL RESISTANCE**

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

Package Type	$\theta_{JA}$	$\theta_{JC}$	$\theta_{JB}$	Unit
20-Lead WLCSP <sup>1</sup>	46.8	0.7	9.2	°C/W

<sup>1</sup> 5 × 4 array, 0.5 mm pitch (2.75 mm × 2.08 mm); based on a JEDEC, 2S2P, 4-layer board with 0 m/sec airflow.

**Maximum Power Dissipation**

The maximum safe power dissipation in the [ADP5065](#) package is limited by the associated rise in junction temperature ( $T_J$ ) on the die. At approximately 150°C, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit may change the stresses that the package exerts on the die, permanently shifting the parametric performance of the [ADP5065](#). Exceeding a junction temperature of 175°C for an extended period of time can result in changes in the silicon devices that potentially cause failure.

**ESD CAUTION**

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 3. Pin Configuration

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Type <sup>1</sup>	Description
D3, E3	SW1, SW2	I/O	DC-to-DC Converter Inductor Connection. These pins are high current outputs when in charging mode.
D1, E1	VIN1, VIN2	I/O	Power Connection to USB VBUS. These pins are high current inputs when in charging mode.
D4, E4	PGND1, PGND2	G	Charger Power Ground. These pins are high current inputs when in charging mode.
C2	AGND	G	Analog Ground.
E2	CFILT	I/O	4.7 $\mu$ F Filter Capacitor Connection. This pin is a high current input/output when in charging mode.
C3, C4	ISO_S1, ISO_S2	I/O	Charger Supply Side Input to Internal Isolation FET/Battery Current Regulation FET.
B3, B4	ISO_B1, ISO_B2	I/O	Battery Supply Side Input to Internal Isolation FET/Battery Current Regulation FET.
A2	SCL	I	I <sup>2</sup> C-Compatible Interface Serial Clock.
B1	SDA	I/O	I <sup>2</sup> C-Compatible Interface Serial Data.
A4	IIN_EXT	I	Set Input Current Limit. This pin sets the input current limit directly. When IIN_EXT = low or high-Z, the input limit is 100 mA. When IIN_EXT = high, the input limit is 500 mA.
B2	TRK_EXT	I	Enable Trickle Charge Function. When TRK_EXT = low or high-Z, the trickle charge is enabled. When TRK_EXT = high, the trickle charge is disabled.
A3	THR	I	Battery Pack Thermistor Connection. If not used, connect a dummy 10 k $\Omega$ resistor from THR to GND.
C1	BAT_SNS	I	Battery Voltage Sense Pin.
D2	SYS_ON_OK	O	Battery Okay Open-Drain Output Flag. Active low. This pin enables the system when the battery reaches V <sub>WEAK</sub> .
A1	V_WEAK_SET	I/O	External Resistor Setting Pin for V_WEAK threshold. The use of this pin is optional. When not in use, connect to GND.

<sup>1</sup> I is input, O is output, I/O is input/output, and G is ground.

## THEORY OF OPERATION

### INTRODUCTION

The [ADP5065](#) is a fully I<sup>2</sup>C-programmable charger for single-cell lithium-ion or lithium-polymer batteries suitable for a wide range of portable applications.

The highly efficient switcher dc-to-dc architecture enables higher charging currents as well as a lower temperature charging operation that results in faster charging times because of the following features:

- 3 MHz switch mode charger.
- 1.25 A charge current from dedicated charger.
- Up to 680 mA of charging current from a 500 mA USB host.

The [ADP5065](#) operates from an input voltage from 4 V to 5.5 V but is tolerant of voltages of up to 20 V. This alleviates the concern about USB bus spiking during disconnection or connection scenarios.

The [ADP5065](#) features an internal FET between the dc-to-dc charger output and the battery. This permits battery isolation and, hence, system powering in a dead battery or no battery scenario, which allows for immediate system function on connection to a USB power supply.

The [ADP5065](#) is fully compliant with the USB 3.0 battery charging specification and enables charging via the mini USB VBUS pin from a wall charger, car charger, or USB host port. Based on the type of USB source, which is detected by an external USB detection device, the [ADP5065](#) can be set to apply the correct current limit for optimal charging and USB compliance. The USB charger permits correct operation under all USB compliant sources such as, wall chargers, host chargers, hub chargers, and standard hosts and hubs.

A processor is able to control the USB charger using the I<sup>2</sup>C to program the charging current and numerous other parameters including

- Trickle charge current level.
- Trickle charge voltage threshold.
- Weak charge (constant current) charge current level.
- Fast charge (constant current) charge current level.
- Fast charge (constant voltage) charge voltage level at 1% accuracy.
- Fast charge safety timer period.
- Watchdog safety timer parameters.
- Weak battery threshold detection.
- Charge complete threshold.
- Recharge threshold.
- Charge enable/disable.
- Battery pack temperature detection and automatic charger shutdown.

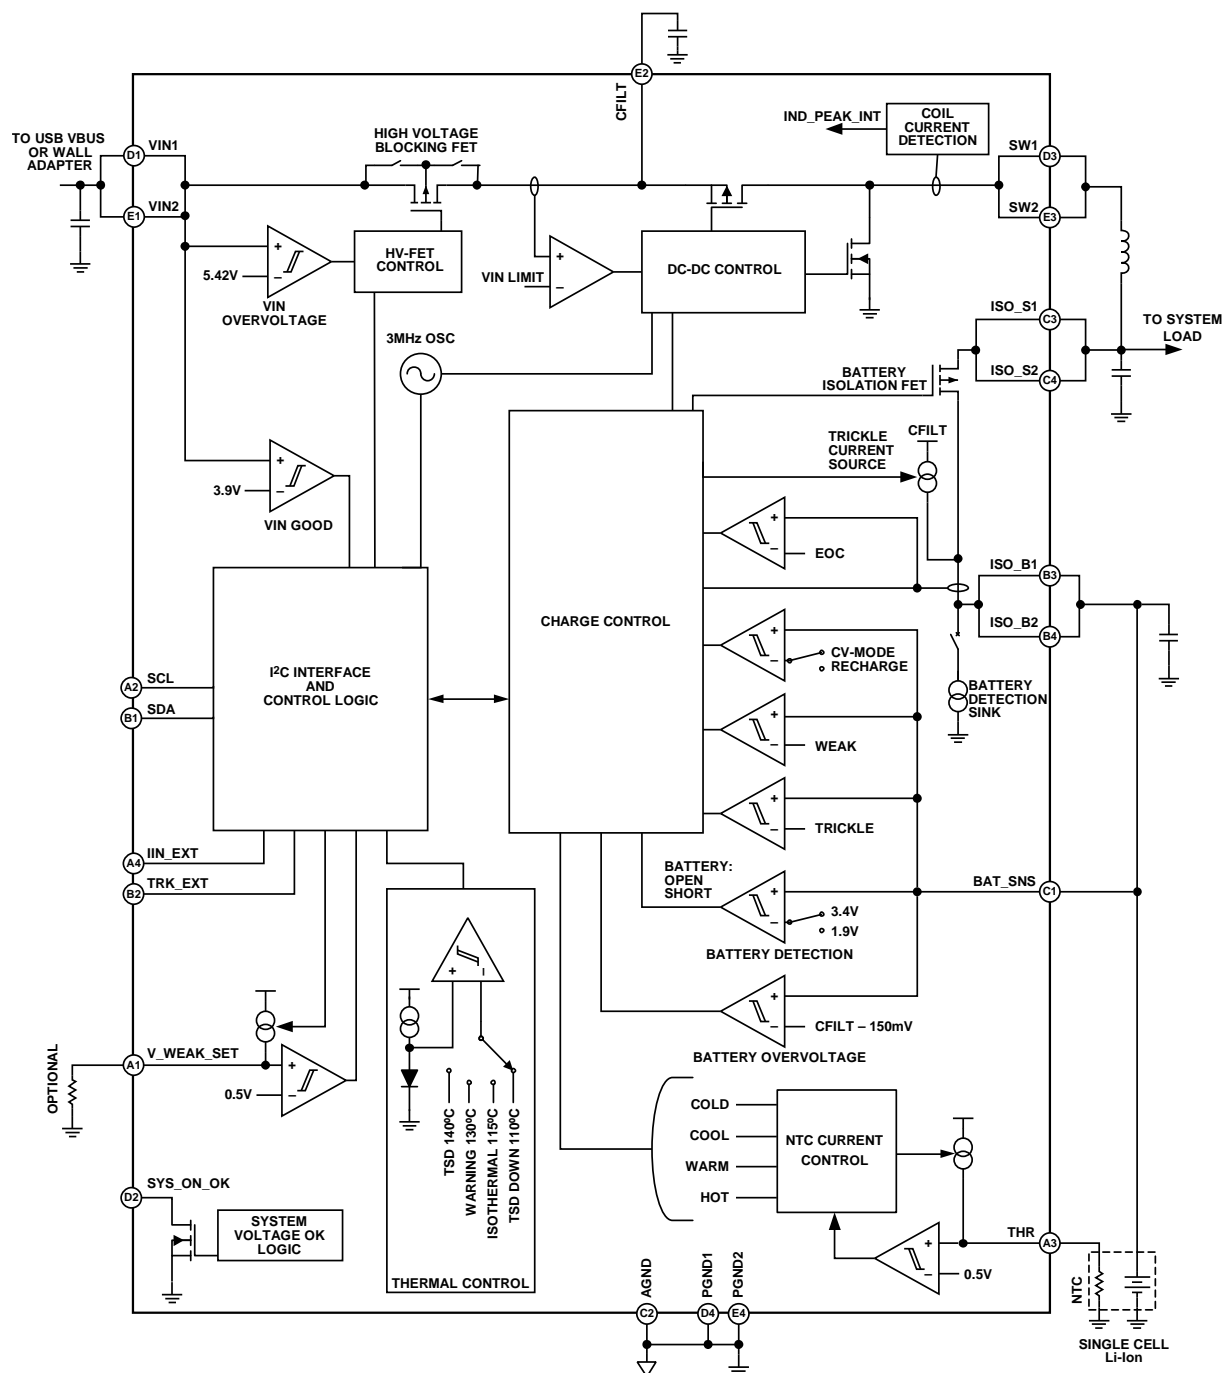

Figure 31. Block Diagram

06370-031

The ADP5065 also includes a number of significant features to optimize charging and functionality, including

- Thermal regulation for maximum performance.
- USB host current-limit accuracy:  $\pm 5\%$ .
- Termination voltage accuracy:  $\pm 1\%$ .
- Battery thermistor input with automatic charger shutdown in the event that the battery temperature exceeds limits. (Compliant with the JEITA Li-Ion battery charging temperature specification.)
- Offloads processor to manage external pin (TRK\_EXT) control to enable/disable trickle charging.
- Direct external pin (IIN\_EXT) control of 100 mA or 500 mA input current limit.
- Optional external resistor programming input, V\_WEAK\_SET, which is used for setting the  $V_{WEAK}$  threshold. When the battery reaches the  $V_{WEAK}$  threshold, the ADP5065 pulls down the SYS\_EN\_OK open-drain output flag. The flag can be used to hold off system turn on until the battery is at the minimum required level for a guaranteed system startup.

## CHARGER MODES

### Input Current Limit

The VINx input current limit is controlled via an internal I<sup>2</sup>C ILIM register. The input current limit can also be controlled via the IIN\_EXT pin as outlined in Table 7. Any change in the I<sup>2</sup>C default from 100 mA dominates over the pin setting.

**Table 7. IIN\_EXT Operation**

IIN_EXT	Function
0	100 mA input current limit or I <sup>2</sup> C programmed value
1	500 mA input current limit or I <sup>2</sup> C programmed value (or reprogrammed I <sup>2</sup> C value from 100 mA default)

### USB Compatibility

The ADP5065 charger provides support for the following connections through the single connector VINx pin.

The ADP5065 features a programmable input current limit to ensure compatibility with the requirements listed in Table 8. The current limit defaults to 100 mA to allow compatibility with a USB host or hub that is not configured.

The I<sup>2</sup>C register default is 100 mA. An I<sup>2</sup>C write command to the ILIM register overrides the IIN\_EXT pin and the I<sup>2</sup>C register default value can be reprogrammed for alternative requirements.

When the input current limiting feature is used, the available input current may be too low for the charger to meet the programmed charging current, I<sub>CHG</sub>, and the rate of charge is reduced. In this case, the VIN\_ILIM flag is set.

When connecting voltage to VINx without having the proper voltage level on the battery side, the HV blocking part is in a state wherein it draws only 1.3 mA (typical) of current until the V<sub>IN</sub> has reached the VIN\_OK level.

**Table 8. Input Current Compatibility with Standard USB Limits**

Mode	Standard USB Limit	ADP5065 Function
USB (China Only)	100 mA limit for standard USB host or hub	100 mA input current limit or I <sup>2</sup> C programmed value
	300 mA limit for Chinese USB specification	300 mA input current limit or I <sup>2</sup> C programmed value
USB 2.0	100 mA limit for standard USB host or hub	100 mA input current limit or I <sup>2</sup> C programmed value
	500 mA limit for standard USB host or hub	500 mA input current limit or I <sup>2</sup> C programmed value
USB 3.0	150 mA limit for super speed USB 3.0 host or hub	150 mA input current limit or I <sup>2</sup> C programmed value
	900 mA limit for super speed, high speed USB host or hub charger	900 mA input current limit or I <sup>2</sup> C programmed value
Dedicated Charger	1500 mA limit for dedicated charger or low/full speed USB host or hub charger	1500 mA input current limit or I <sup>2</sup> C programmed value

### Trickle Charge Mode

A deeply discharged Li-Ion cell may exhibit a very low cell voltage making it unsafe to charge the cell at high current rates. The ADP5065 charger uses a trickle charge mode to reset the battery pack protection circuit and lift the cell voltage to a safe level for fast charging. A cell with a voltage below  $V_{TRK\_DEAD}$  is charged with the trickle mode current, I<sub>TRK\\_DEAD</sub>. During trickle charging mode, the CHARGER\_STATUS register is set.

During trickle charging, the ISO\_Sx node is regulated to V<sub>ISO\_STRK</sub> by the dc-to-dc converter and the battery isolation FET is off, which means the battery is isolated from the system power supply.

Trickle charging can be controlled via the TRK\_EXT external pin (see Table 9). Note that any change in the I<sup>2</sup>C EN\_TRK bit dominates over the pin setting.

**Table 9. TRK\_EXT Operation**

TRK_EXT	Function
0	Trickle charge enabled
1	Trickle charge disabled

### Trickle Charge Mode Timer

The duration of trickle charge mode is monitored to ensure the battery is revived from its deeply discharged state. If trickle charge mode runs for longer than 60 minutes without the cell voltage reaching  $V_{TRK\_DEAD}$ , a fault condition is assumed and charging stops. The fault condition is asserted on the CHARGER\_STATUS register, allowing the user to initiate the fault recovery procedure specified in the Fault Recovery section.

**Weak Charge Mode (Constant Current)**

When the battery voltage exceeds  $V_{TRK\_DEAD}$  but is less than  $V_{WEAK}$ , the charger switches to the intermediate charge mode.

During the weak charge mode, the battery voltage is too low to allow the full system to power-up. Due to the low level of the battery, the USB transceiver cannot be powered and, therefore, cannot enumerate for more current from a USB host. Consequently, the USB limit remains at 100 mA.

The system microcontroller may or may not be powered by the charger output voltage ( $V_{ISO\_SFC}$ ) depending upon the amount of current required by the microcontroller and/or the system architecture. In this case, the battery charge current ( $I_{CHG\_WEAK}$ ) cannot be increased above 20 mA to ensure the microcontroller can still operate (if doing so) nor increased above the 100 mA USB limit. Thus, set the battery charging current as follows:

- Set the default 20 mA via the linear trickle charger branch (to ensure that the microprocessor remains alive if powered by the main switching charger output, ISO\_Sx). Any residual current on the main switching charger output, ISO\_Sx, is used to charge the battery at up to the preprogrammed level in the I<sup>2</sup>C for  $I_{CHG}$  (fast charge current limit) or  $I_{LIM}$  (input current limit).
- During weak current mode, other features may prevent the actual programmed weak charging current from reaching its full programmed value. Isothermal charging mode or input current limiting for USB compatibility may affect the programmed weak charging current value under certain operating conditions. During weak charging, the ISO\_Sx node is regulated to  $V_{ISO\_SFC}$  by the battery isolation FET.

**Fast Charge Mode (Constant Current)**

When the battery voltage exceeds  $V_{TRK\_DEAD}$  and  $V_{WEAK}$ , the charger switches to fast charge mode, charging the battery with the constant current,  $I_{CHG}$ . During fast charge mode (constant current), the CHARGER\_STATUS register is set.

During constant current mode, other features may prevent the current,  $I_{CHG}$ , from reaching its full programmed value. Isothermal charging mode or input current limiting for USB compatibility may affect the value of  $I_{CHG}$  under certain operating conditions. The voltage on ISO\_Sx is regulated to stay at  $V_{ISO\_SFC}$  by the battery isolation FET when  $V_{ISO\_B} < V_{ISO\_SFC}$ .

**Fast Charge Mode (Constant Voltage)**

As the battery charges, its voltage rises and approaches the termination voltage,  $V_{TRM}$ . The ADP5065 charger monitors the voltage on the BAT\_SNS pin to determine when charging should end. However, the internal ESR of the battery pack combined with PCB and other parasitic series resistances creates a voltage drop between the sense point at the BAT\_SNS pin and the cell terminal itself. To compensate for this and ensure a fully charged cell, the ADP5065 enters a constant voltage charging mode when the termination voltage is detected on the BAT\_SNS pin. The ADP5065 reduces charge current gradually as the cell continues to charge, maintaining a voltage of  $V_{TRM}$  on the BAT\_SNS pin. During fast charge mode (constant voltage), the CHARGER\_STATUS register is set.

**Fast Charge Mode Timer**

The duration of fast charge mode is monitored to ensure that the battery is charging correctly. If the fast charge mode runs for longer than  $t_{CHG}$  without the voltage at the BAT\_SNS pin reaching  $V_{TRM}$ , a fault condition is assumed and charging stops. The fault condition is asserted on the CHARGER\_STATUS register allowing the user to initiate the fault recovery procedure specified in the Fault Recovery section.

If the fast charge mode runs for longer than  $t_{CHG}$ , and  $V_{TRM}$  has been reached on the BAT\_SNS pin but the charge current has not yet fallen below  $I_{END}$ , charging stops. No fault condition is asserted in this circumstance and charging resumes as normal if the recharge threshold is breached.

**Watchdog Timer**

The ADP5065 charger features a programmable watchdog timer function to ensure charging is under the control of the processor. The watchdog timer starts running when the ADP5065 charger determines that the processor should be operational, that is, when the processor sets the RESET\_WD bit for the first time or when the battery voltage is greater than the weak battery threshold,  $V_{WEAK}$ . When the watchdog timer has been triggered, it must be reset regularly within the watchdog timer period,  $t_{WD}$ .

If the watchdog timer expires without being reset while in charger mode, the ADP5065 charger assumes there is a software problem and triggers the safety timer,  $t_{SAFE}$ . For more information see the Safety Timer section.

**Safety Timer**

If the watchdog timer (see the Watchdog Timer section for more information) expires while in charger mode, the ADP5065 charger initiates the safety timer,  $t_{SAFE}$ . If the processor has programmed charging parameters by this time, the  $I_{LIM}$  is set to the default value. Charging continues for a period of  $t_{SAFE}$ , then the charger switches off and sets the CHARGER\_STATUS register.

**Charge Complete**

The ADP5065 charger monitors the charging current while in constant voltage fast charge mode. If the current falls below  $I_{END}$  and remains below  $I_{END}$  for  $t_{END}$ , charging stops and the CHDONE flag is set. If the charging current falls below  $I_{END}$  for less than  $t_{END}$  and then rises above  $I_{END}$  again, the  $t_{END}$  timer resets.

**Recharge**

After the detection of charge complete, and the cessation of charging, the ADP5065 charger monitors the BAT\_SNS pin as the battery discharges through normal use. If the BAT\_SNS pin voltage falls to  $V_{RCH}$ , the charger reactivates charging. Under most circumstances, triggering the recharge threshold results in the charger starting directly into fast charge constant voltage mode.

**Battery Charging Enable/Disable**

The ADP5065 charging function can be disabled by setting the I<sup>2</sup>C EN\_CHG bit to low.

**THERMAL MANAGEMENT****Isothermal Charging**

To assist with the thermal management of the ADP5065 charger, the battery charger provides an isothermal charging function. As the on-chip power dissipation and die temperature increase, the ADP5065 charger monitors die temperature and limits output current when the temperature reaches  $T_{LIM}$  (typically at 115°C). The die temperature is maintained at  $T_{LIM}$  through the control of the charging current into the battery. A reduction in power dissipation or ambient temperature may allow the charging current to return to its original value, and the die temperature subsequently drops below  $T_{LIM}$ . During isothermal charging, the THERM\_LIM flag is set to high.

**Thermal Shutdown and Thermal Early Warning**

The ADP5065 switching charger features a thermal shutdown threshold detector. If the die temperature exceeds  $T_{SD}$ , the ADP5065 charger is disabled, and the TSD 140°C bit is set. The ADP5065 charger can be reenabled when the die temperature drops below the  $T_{SD}$  falling limit and the TSD 140°C bit is reset. To reset the TSD 140°C bit, write to the I<sup>2</sup>C Fault Register 0x0D or cycle the power.

Before die temperature reaches  $T_{SD}$ , the early warning bit is set if  $T_{SDL}$  is exceeded. This allows the system to accommodate power consumption before thermal shutdown occurs.

**Fault Recovery**

Before performing the following operation, it is important to ensure that the cause of the fault has been rectified.

To recover from a charger fault (when the CHARGER\_STATUS equals 110), cycle power on VINx or write high to reset the I<sup>2</sup>C fault bits in the fault register.

**BATTERY ISOLATION FET**

The ADP5065 charger features an integrated battery isolation FET for power path control. The battery isolation FET isolates a deeply discharged Li-Ion cell from the system power supply in both trickle and fast charge modes, thereby allowing the system to be powered at all times.

When VINx is below  $V_{VIN\_OK}$ , the battery isolation FET is in full conducting mode.

The battery isolation FET is off during trickle charge mode. When the battery voltage exceeds  $V_{TRK}$ , the battery isolation FET switches to the system voltage regulation mode. During system voltage regulation mode, the battery isolation FET maintains the  $V_{ISO\_SFC}$  voltage on the ISO\_Sx pins. When the battery voltage exceeds  $V_{ISO\_SFC}$ , the battery isolation FET is in full conducting mode.

The battery isolation FET supplements the battery to support high current functions on the system power supply.

When voltage on ISO\_Sx drops below ISO\_Bx, the battery isolation FET enters into full conducting mode.

When voltage on ISO\_Sx rises above ISO\_Bx, the isolation FET enters regulating mode or full conduction mode, depending on the Li-Ion cell voltage and the dc-to-dc charger mode.

## BATTERY DETECTION

### Battery Level Detection

The ADP5065 charger features a battery detection mechanism to detect an absent battery. The charger actively sinks and sources current into the ISO\_Bx/BAT\_SNS node, and voltage vs. time is detected. The sink phase is used to detect a charged battery, whereas the source phase is used to detect a discharged battery.

The sink phase (see Figure 32) sinks  $I_{\text{SINK}}$  current from the ISO\_Bx/ BAT\_SNS pins for a time,  $t_{\text{BATOK}}$ . If the BAT\_SNS pin is below  $V_{\text{BATL}}$  when the  $t_{\text{BATOK}}$  timer expires, the charger assumes no battery is present, and starts the source phase. If the BAT\_SNS exceeds the  $V_{\text{BATL}}$  voltage when the  $t_{\text{BATOK}}$  timer expires, the charger assumes the battery is present, and begins a new charge cycle.

The source phase sources  $I_{\text{SOURCE}}$  current to ISO\_Bx or the BAT\_SNS pins for a time,  $t_{\text{BATOK}}$ . If the BAT\_SNS pin exceeds  $V_{\text{BATH}}$  before the  $t_{\text{BATOK}}$  timer expires, the charger assumes that no battery is present. If the BAT\_SNS does not exceed the  $V_{\text{BATH}}$  voltage when the  $t_{\text{BATOK}}$  timer expires, the charger assumes that a battery is present, and begins a new charge cycle.

### Battery (ISO\_Bx) Short Detection

A battery short occurs under a damaged battery condition or when the battery protection circuitry is enabled.

On commencing trickle charging, the ADP5065 charger monitors the battery voltage. If this battery voltage does not exceed  $V_{\text{BAT_SHR}}$  within the specified timeout period,  $t_{\text{BAT_SHR}}$ , a fault is declared and the charger is stopped by turning the battery isolation FET off but the system voltage is maintained at  $V_{\text{ISO_STRK}}$  by the linear regulator.

The trickle charge branch is active during the battery short scenario, and trickle charge current to the battery is maintained until the 60 minute trickle charge mode timer expires.

After source phase, if the ISO\_Bx or BAT\_SNS level remains below  $V_{\text{BATH}}$ , either the battery voltage is low or the battery node can be shorted. As a result of the battery voltage being low, trickle charging mode is initiated (see Figure 33). If the BAT\_SNS level remains below  $V_{\text{BAT_SHR}}$  after  $t_{\text{BAT_SHR}}$  has elapsed, the ADP5065 assumes that the battery node is shorted.

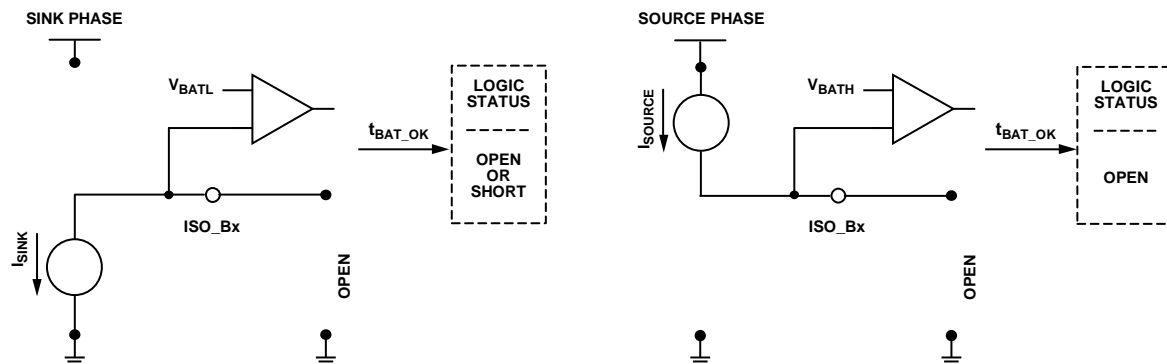

Figure 32. Battery Detection Sequence

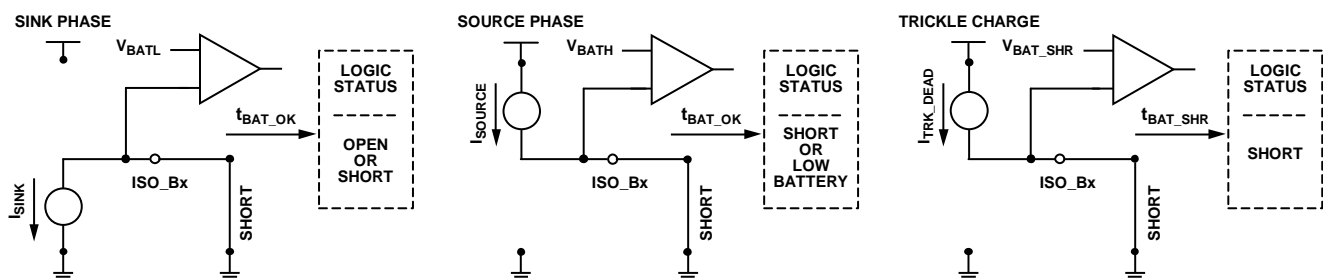

Figure 33. Battery Short Detection Sequence

## BATTERY PACK TEMPERATURE SENSING

### Battery Thermistor Input

The ADP5065 charger features battery pack temperature sensing that precludes charging when the battery pack temperature is outside the specified range. The THR pin provides an on and off switching current source, which should be connected directly to the battery pack thermistor terminal. The activation interval of the THR current source is 167 ms.

The battery pack temperature sensing can be controlled by I<sup>2</sup>C using the conditions shown in Table 10. Note that the I<sup>2</sup>C register default setting for EN\_THR (Register 0x07) is 0 = temperature sensing off.

**Table 10. THR Input Function**

Conditions		THR Function
VINx	V <sub>ISO_B</sub>	
Open or V <sub>IN</sub> = 0 V to 4.0 V	<2.5 V	Off
Open or V <sub>IN</sub> = 0 V to 4.0 V	>2.5 V	Off, controlled by I <sup>2</sup> C
4.0 V to 5.5 V	Don't care	Always on

If the battery pack thermistor is not connected directly to the ADP5065 THR pin, a 10 kΩ (tolerance ±20%) dummy resistor must be connected between the THR input and GND. Leaving the THR pin open results in a false detection of the battery temperature being <0°C and charging is disabled.

The ADP5065 charger monitors the voltage in the THR pin and suspends charging if the current is outside the range of less than 0°C or greater than 60°C. For temperatures greater than 0°C, the THR\_STATUS register is set accordingly, and for temperatures lower than 60°C, the THR\_STATUS register is, likewise, set accordingly.

The ADP5065 charger is designed for use with an NTC thermistor in the battery pack with a nominal room temperature value of either 10 kΩ at 25°C or 100 kΩ at 25°C, which is selected by a fuse.

The ADP5065 charger is designed for use with an NTC thermistor in the battery pack with a temperature coefficient curve (beta). Fuse-selectable beta programming is supported by eight steps covering a range from 3150 to 4400 (see Table 34).

### JEITA Li-Ion Battery Temperature Charging Specification

The ADP5065 is compliant with the JEITA Li-Ion battery charging temperature specifications as outlined in Table 11.

The JEITA function can be enabled via the I<sup>2</sup>C interface. When the ADP5065 detects a JEITA cool condition, charging current is reduced according to Table 12.

When the ADP5065 identifies a hot or cold battery condition, the ADP5065 takes the following actions:

- Stops charging the battery.
- Connects/enables the battery isolation FET such that the system power supply node is connected to the battery.

**Table 11. JEITA Li-Ion Battery Charging Specification Defaults**

Parameter	Symbol	Conditions	Min	Max	Unit
JEITA Cold Temperature Limits	I <sub>JEITA_COLD</sub>	No battery charging occurs.		0	°C
JEITA Cool Temperature Limits	I <sub>JEITA_COOL</sub>	Battery charging occurs at approximately 50% of programmed level. See Table 12 for specific charging current reduction levels.	0	10	°C
JEITA Typical Temperature Limits	I <sub>JEITA_TYP</sub>	Normal battery charging occurs at default/programmed levels.	10	45	°C
JEITA Warm Temperature Limits	I <sub>JEITA_WARM</sub>	Battery termination voltage (V <sub>TRM</sub> ) is reduced by 100 mV from programmed value.	45	60	°C
JEITA Hot Temperature Limits	I <sub>JEITA_HOT</sub>	No battery charging occurs.	60		°C

**Table 12. JEITA Reduced Charge Current Levels**

JEITA Cool Temperature Limit—Reduced Charge Current Levels	
ICHG[2:0] (Default)	ICHG JEITA (mA)
000 = 550 mA	250
001 = 650 mA	300
010 = 750 mA	350
011 = 850 mA	400
100 = 950 mA	450
101 = 1050 mA	500
110 = 1150 mA	550
111 = 1250 mA	600

EXTERNAL RESISTOR FOR V\_WEAK\_SET

The ADP5065 charger features a V<sub>WEAK</sub> threshold, which can be used for enabling the main PMU system. When battery voltage at the BAT\_SNS pin exceeds the V<sub>WEAK</sub> level, the ADP5065 pulls down the SYS\_ON\_OK open-drain flag.

The V<sub>WEAK</sub> threshold can be programmed set either by I<sup>2</sup>C or by an external resistor connected between the V\_WEAK\_SET pin and GND. Recommended resistor values for each threshold are listed in Table 13.

If an external resistor is not used, it is recommended to tie the V\_WEAK\_SET pin to AGND for V<sub>WEAK</sub> to obtain its default value.

Table 13. Resistor Values for V\_WEAK\_SET Pin

Target Resistor Value E24 (kΩ)	Actual Threshold (kΩ)	V <sub>WEAK</sub> Voltage (Rising Threshold)	V <sub>WEAK</sub> Voltage (Falling Threshold)
Short to GND	Not applicable	I <sup>2</sup> C (3.0 V default)	I <sup>2</sup> C programmed – 100 mV
15	13.2	2.7 V	2.6 V
20	17.8	2.8 V	2.7 V
27	23.5	2.9 V	2.8 V
36	31.0	3.0 V	2.9 V
47	41.3	3.1 V	3.0 V
68	56.2	3.2 V	3.1 V
100	79.7	3.3 V	3.2 V
Open	122.4	3.4 V	3.3 V

## I<sup>2</sup>C INTERFACE

The ADP5065 includes an I<sup>2</sup>C-compatible serial interface for control of the charging and for a readback of system status registers. The I<sup>2</sup>C chip address is 0x28 in write mode and 0x29 in read mode.

Register values are reset to the default values, when the supply voltage at the VINx pin falls below the V<sub>VIN\_OK</sub> falling voltage threshold. The I<sup>2</sup>C registers are also reset when the battery is disconnected and V<sub>IN</sub> is 0 V.

See Figure 34 for an example of the I<sup>2</sup>C write sequence to a single register. The subaddress content selects which one of the five ADP5065 registers is written to first. The ADP5065 sends an acknowledgement to the master after the 8-bit data byte has been written. The ADP5065 increments the subaddress automatically and starts receiving a data byte to the following register until the master sends an I<sup>2</sup>C stop as shown in Figure 35.

Figure 36 shows the I<sup>2</sup>C read sequence of a single register. ADP5065 sends the data from the register denoted by the subaddress and increments the subaddress automatically, sending data from the next register until the master sends an I<sup>2</sup>C stop condition as shown in Figure 37.

## APPLICATIONS INFORMATION

### EXTERNAL COMPONENTS

#### Inductor Selection

The high switching frequency of the [ADP5065](#) buck converter allows for the selection of small chip inductors. Suggested inductors are shown in Table 33.

The peak-to-peak inductor current ripple is calculated using the following equation:

$$I_{RIPPLE} = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times L}$$

where:

$V_{OUT}$  is the ISO\_Sx node output voltage.

$V_{IN}$  is the converter input voltage at the CFILT node.

$f_{SW}$  is the switching frequency.

$L$  is the inductor value.

The minimum dc current rating of the inductor must be greater than the inductor peak current. The inductor peak current is calculated using the following equation:

$$I_{PEAK} = I_{CHG} + I_{LOAD(MAX)} + \frac{I_{RIPPLE}}{2}$$

Inductor conduction losses are caused by the flow of current through the inductor, which has an associated internal dc resistance (DCR). Larger sized inductors have smaller DCR, which may decrease inductor conduction losses. Inductor core losses are related to the magnetic permeability of the core material. Because the bucks are high switching frequency dc-to-dc converters, shielded ferrite core material is recommended for its low core losses and low EMI.

#### ISO\_Sx ( $V_{OUT}$ ) and ISO\_Bx Capacitor Selection

To safely obtain stable operation of the [ADP5065](#), the ISO\_Sx and ISO\_Bx effective capacitance (including temperature and dc bias effects) must not be less than 10  $\mu$ F at any point during operation. The combined effective capacitance of the ISO\_Sx capacitor and the system capacitance must not exceed 50  $\mu$ F at any point during operation.

Higher output capacitor values reduce the output voltage ripple and improve load transient response. When choosing this value, it is also important to account for the loss of capacitance due to output voltage dc bias.

Ceramic capacitors are manufactured with a variety of dielectrics, each with a different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate enough to ensure the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended for best performance. Y5V and Z5U dielectrics are not recommended for use with any dc-to-dc converter because of their poor temperature and dc bias characteristics.

The worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage is calculated using the following equation:

$$C_{EFF} = C_{OUT} \times (1 - TEMP_{CO}) \times (1 - TOL)$$

where:

$C_{EFF}$  is the effective capacitance at the operating voltage.

$TEMP_{CO}$  is the worst-case capacitor temperature coefficient.

$TOL$  is the worst-case component tolerance.

In this example, the worst-case temperature coefficient ( $TEMP_{CO}$ ) over  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  is assumed to be 15% for an X5R dielectric. The tolerance of the capacitor ( $TOL$ ) is assumed to be 10%, and  $C_{OUT}$  is 16  $\mu$ F at 4.2 V, as shown in Figure 39.

Substituting these values in the equation yields

$$C_{EFF} = 16 \mu\text{F} \times (1 - 0.15) \times (1 - 0.1) \approx 12.24 \mu\text{F}$$

Figure 39. Murata GRM31CR60J226ME19C DC Characteristic

To guarantee the performance of the charger in various operation modes including trickle charge, constant current charge, and constant voltage charge, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors be evaluated for each application.

The peak-to-peak output voltage ripple for the selected output capacitor and inductor values is calculated using the following equation:

$$V_{RIPPLE} = \frac{I_{RIPPLE}}{8 \times f_{SW} \times C_{OUT}} \approx \frac{V_{IN}}{(2\pi \times f_{SW})^2 \times L \times C_{OUT}}$$

Capacitors with lower effective series resistance (ESR) are preferable to guarantee low output voltage ripple, as shown in the following equation:

$$ESR_{COUT} \leq \frac{V_{RIPPLE}}{I_{RIPPLE}}$$

**VINx Capacitor Selection**

According to the USB 2.0 specification, USB peripherals have a detectable change in capacitance on VBUS when they are attached. The peripheral device VBUS bypass capacitance must be at least 1 µF but not larger than 10 µF. The combined capacitance for the VINx and CFILT pins must not exceed 10 µF at any temperature or dc bias condition. Suggestions for a VINx capacitor is given in Table 32.

**CFILT Capacitor Selection**

CFILT pin serves the ADP5065 as the step-down dc-to-dc converter input capacitor. Maximum input capacitor current is calculated using the following equation:

$$I_{CIN} \geq I_{LOAD+CHG(MAX)} \sqrt{\frac{V_{ISO\_S} (V_{CFILT} - V_{ISO\_S})}{V_{CFILT}}}$$

To minimize supply noise, place the input capacitor as close as possible to the CFILT pin of the charger. As with the output capacitor, a low ESR capacitor is recommended.

The effective capacitance needed for stability, which includes temperature and dc bias effects, is a minimum of 2 µF and a maximum of 5 µF. A list of suggested capacitors is shown in Table 31.

Poor layout can affect [ADP5065](#) performance, causing electromagnetic interference (EMI) and electromagnetic compatibility (EMC) problems, ground bounce, and voltage losses. Poor layout can also affect regulation and stability. A good layout is implemented using the following guidelines:

- Route the output voltage path away from both the inductor and SWxnode to minimize noise and magnetic interference.
- Maximize the size of ground metal on the component side to help with thermal dissipation.
- Use a ground plane with several vias connecting to the component side ground to further reduce noise interference on sensitive circuit nodes.

Figure 1 illustrates the PCB layout for the ADP5065. The layout includes the ADP5065 IC, input capacitors ( $C_{IN}$ ,  $C_{ISO\_B}$ ,  $C_{ISO\_S}$ ), a filter capacitor ( $C_{CFILT}$ ), and an inductor ( $L$ ). The input voltage ( $V_{IN}$ ) is applied to the input section. The layout dimensions are 8mm for the input section and 11.5mm for the main section. The ground connections are labeled PGND.

1000

## POWER DISSIPATION AND THERMAL CONSIDERATIONS

The ADP5065 is a highly efficient USB compliant charger. However, if the device operates at high ambient temperatures and maximum current charging and loading conditions, the junction temperature can reach the maximum allowable operating limit (125°C).

When the temperature exceeds 140°C, the ADP5065 turns off allowing the device to cool down. When the die temperature falls below 110°C and the TSD 140°C fault bit in Register 0x0D is cleared by an I<sup>2</sup>C write, the ADP5065 resumes normal operation.

This section provides guidelines to calculate the power dissipated in the device and ensure that the ADP5065 operates below the maximum allowable junction temperature.

The output power of the ADP5065 charger is given by

$$P_{OUT} = V_{ISO\_S} \times I_{LOAD} + V_{ISO\_B} \times I_{CHG} \quad (1)$$

where:

$P_{OUT}$  is the total output power to the system and battery.

$V_{ISO\_S}$  is the ISO\_Sx pin voltage.

$I_{LOAD}$  is the load current from ISO\_Sx node.

$V_{ISO\_B}$  is the battery voltage.

$I_{CHG}$  is the charge current.

The efficiency of the ADP5065 is given by

$$\eta = \frac{P_{OUT}}{P_{IN}} \times 100\% \quad (2)$$

where:

$\eta$  is the efficiency.

$P_{IN}$  is the input power.

Power loss is given by

$$P_{LOSS} = P_{IN} - P_{OUT} \quad (3a)$$

or

$$P_{LOSS} = P_{OUT} (1 - \eta) / \eta \quad (3b)$$

Power dissipation can be calculated in several ways. The most intuitive and practical is to measure the power dissipated at the input and both outputs (ISO\_Sx and ISO\_Bx). Perform the measurements at the worst-case conditions (voltages, currents, and temperature). The difference between input and output power is dissipated in the device and the inductor. Use Equation 5 to derive the power lost in the inductor and, from this, use Equation 4 to calculate the power dissipation in the ADP5065 charger.

A second method to estimate the power dissipation uses the system voltage and charging efficiency curves provided for the ADP5065. When the efficiency is known, use Equation 3b to derive the total power lost in the dc-to-dc converter, isolation FET and inductor; use Equation 5 to derive the power lost in the inductor, and then calculate the power dissipation in the buck converter using Equation 4.

Note that the ADP5065 efficiency curves are typical values and may not be provided for all possible combinations of  $V_{IN}$ ,  $V_{OUT}$ , and  $I_{OUT}$ . To account for these variations, it is necessary to include a safety margin when calculating the power dissipated in the charger.

### CHARGER POWER DISSIPATION

The power loss of the step-down charger is approximated by

$$P_{LOSS} = P_{DCHG} + P_L \quad (4)$$

where:

$P_{DCHG}$  is the power dissipation of the ADP5065 charger.

$P_L$  is the inductor power losses.

The inductor losses are external to the device, and they do not have any effect on the die temperature. Equation 5 estimates the inductor losses without core losses. Some inductor manufacturers provide web tools to estimate power inductor core losses based on inductor type, switching frequency, and ripple current. At a switching frequency of 3 MHz, the core losses can add inductor losses significantly.

$$P_L \approx I_{OUT(RMS)}^2 \times DCR_L \quad (5)$$

where:

$DCR_L$  is the inductor series resistance.

$I_{OUT(RMS)}$  is the summary of rms load current and charging current ( $I_{LOAD(RMS)} + I_{CHG}$ ).

$$I_{OUT(RMS)} = I_{OUT} \times \sqrt{1 + \frac{r}{12}} \quad (6)$$

where  $r$  is the normalized inductor ripple current.

$$r = V_{OUT} \times (1 - D) / (I_{OUT} \times L \times f_{SW}) \quad (7)$$

where:

$L$  is the inductance.

$f_{SW}$  is the switching frequency.

$D$  is the duty cycle.

$$D = V_{OUT} / V_{IN} \quad (8)$$

## JUNCTION TEMPERATURE

In cases where the ambient temperature,  $T_A$ , is known, the thermal resistance parameter,  $\theta_{JA}$ , can be used to estimate the junction temperature rise.  $T_J$  is calculated from  $T_A$  and  $P_D$  using the formula

$$T_J = T_A + (P_D \times \theta_{JA}) \quad (9)$$

The typical  $\theta_{JA}$  value for the 20-bump WLCSP is 46.8°C/W (see Table 5). A very important factor to consider is that  $\theta_{JA}$  is based on a 4-layer, 4 in × 3 in, 2.5 oz copper board as per JEDEC standard, and real applications may use different sizes and layers. It is important to maximize the copper to remove the heat from the device. Copper exposed to air dissipates heat better than copper used in the inner layers.

When designing an application for a particular ambient temperature range, calculate the expected ADP5065 power dissipation ( $P_D$ ). From this power calculation, the junction temperature,  $T_J$ , can be estimated using Equation 9.

Maximum junction temperature ( $T_J$ ) can also be calculated from the board temperature ( $T_B$ ) and power dissipation ( $P_D$ ) using the formula

$$T_J = T_B + (P_D \times \theta_{JB}) \quad (10)$$

where  $\theta_{JB}$  is the junction-to-board thermal resistance.

The typical value for the 20-bump WLCSP is 9.2°C/W (see Table 5).  $\theta_{JB}$  is based on a 4-layer, 4 in × 3 in, 2.5 oz copper board, as per the JEDEC standard.

For a WLCSP device, where possible, remove heat from every current carrying bump (PGNDx, VINx, SWx, ISO\_Sx, and ISO\_Bx). For example, thermal vias to the board power planes can be placed close to these pins, where available.

The reliable operation of the charger can be achieved only if the estimated die junction temperature of the ADP5065 (Equation 9) is less than 125°C. Reliability and mean time between failures (MTBF) are highly affected by increasing the junction temperature. Additional information about product reliability is available in the *ADI Reliability Handbook* at the following URL: [www.analog.com/reliability\\_handbook](http://www.analog.com/reliability_handbook).

## PACKAGING AND ORDERING INFORMATION

### OUTLINE DIMENSIONS

Figure 42. 20-Ball Wafer Level Chip Scale Package [WLCSP]  
(CB-20-8)

Dimensions shown in millimeters

### ORDERING GUIDE

Model <sup>1</sup>	Temperature Range (Junction)	Package Description	Package Option
ADP5065ACBZ-1-R7	−40°C to +125°C	20-Ball Wafer Level Chip Scale Package [WLCSP]	CB-20-8
ADP5065CB-EVALZ		ADP5065 Evaluation Board	

<sup>1</sup> Z = RoHS Compliant Part.

## NOTES

## NOTES

I<sup>2</sup>C refers to a communications protocol originally developed by Philips Semiconductors (now NXP Semiconductors).
