CY7C408A
CY7C409A

64 x 8 Cascadable FIFO
64 x 9 Cascadable FIFO

Features

- **64 x 8 and 64 x 9 first-in first-out (FIFO) buffer memory**
- **35-MHz shift in and shift out rates**
- **Almost Full/Almost Empty and Half Full flags**
- **Dual-port RAM architecture**
- **Fast (50-ns) bubble-through**
- **Independent asynchronous inputs and outputs**
- **Output enable (CY7C408A)**
- **Expandable in word width and FIFO depth**
- **5V ± 10% supply**
- **TTL complete**
- **Capable of withstanding greater than 2001V electro-static discharge voltage**
- **300-mil, 28-pin DIP**

Functional Description

The CY7C408A and CY7C409A are 64-word deep by 8- or 9-bit wide first-in first-out (FIFO) buffer memories. In addition to the industry-standard handshaking signals, almost full/almost empty (AFE) and half-full (HF) flags are provided.

AFE is HIGH when the FIFO is almost full or almost empty, otherwise AFE is LOW. HF is HIGH when the FIFO is half full, otherwise HF is LOW.

The CY7C408A has an output enable (OE) function.

The memory accepts 8- or 9-bit parallel words as its inputs (DI_0 – DI_8) under the control of the shift in (SI) input when the input ready (IR) control signal is HIGH. The data is output, in the same order as it was stored on the DO_0 – DO_8 output pins under the control of the shift out (SO) input when the output ready (OR) control signal is HIGH. If the FIFO is full (IR LOW), pulses at the SI input are ignored; if the FIFO is empty (OR LOW), pulses at the SO input are ignored.

The IR and OR signals are also used to connect the FIFOs in parallel to make a wider word or in series to make a deeper buffer, or both.

Parallel expansion for wider words is implemented by logically ANDing the IR an OR outputs (respectively) of the individual FIFOs together (*Figure 5*). The AND operation insures that all of the FIFOs are either ready to accept more data (IR HIGH) or ready to output data (OR HIGH) and thus compensate for variations in propagation delay times between devices.

Serial expansion (cascading) for deeper buffer memories is accomplished by connecting data outputs of the FIFO closet to the data source (upstream device) to the data inputs of the following (downstream) FIFO (*Figure 4*). In addition, to insure proper operation, the SO signal of the upstream FIFO must be connected to the OR output of the upstream FIFO. In this serial expansion configuration, the IR and OR signals are used to pass data through the FIFOs.

Reading and writing operations are completely asynchronous, allowing the FIFO to be used as a buffer between two digital machines of widely differing operating frequencies. The high shift in and shift out rates of these FIFOs, and their throughput rate due to the fast bubblethrough time, which is due to their dual-port RAM architecture, make them ideal for high-speed communications and controllers.

Notes:

6. Test conditions assume signal transition time of 5 ns or less, timing reference levels of 1.5V and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance, as in parts (a) and (b) of AC Test Loads and Waveforms.
7. $1/f_O \geq (t_{PHSI} + t_{PLSI})$, $1/f_O \geq (t_{PHSO} + t_{PLSO})$.
8. t_{SSI} and t_{HSI} apply when memory is not full.
9. t_{SIR} and t_{HIR} apply when memory is full, SI is high and minimum bubble-through (t_{BT}) conditions exist.
10. At any given operating condition $t_{PIR} \geq (t_{PHSO}$ required).
11. At any given operating condition $t_{POR} \geq (t_{PHSI}$ required).
12. t_{DHZOE} and t_{DLZOE} are specified with C_L = 5 pF as in part (b) of AC Test Loads and Waveforms. t_{DHZOE} transition is measured ±500 mV from steady-state voltage. t_{DLZOE} transition is measured ±100 mV from steady-state voltage. These parameters are guaranteed and not 100% tested.
13. All data outputs will be at LOW level after reset goes HIGH until data is entered into the FIFO.

Architecture of the CY7C408A and CY7C409A

The CY7C408A and CY7C409A FIFOs consist of an array of 64 words of 8 or 9 bits each (which are implemented using a dual-port RAM cell), a write pointer, a read pointer, and the control logic necessary to generate the handshaking (SI/IR, SO/OR) signals as well as the almost full/almost empty (AFE) and half full (HF) flags. The handshaking signals operate in a manner identical to those of the industry standard CY7C401/402/403/404 FIFOs.

Dual-Port RAM

The dual-port RAM architecture refers to the basic memory cell used in the RAM. The cell itself enables the read and write operations to be independent of each other, which is necessary to achieve truly asynchronous operation of the inputs and outputs. A second benefit is that the time required to increment the read and write pointers is much less than the time that would be required for data to propagate through the memory, which it would have to do if the memory were implemented using the conventional register array architecture.

Fall-Through and Bubble-Back

The time required for data to propagate from the input to the output of an initially empty FIFO is defined as the fall-through time.

The time required for an empty location to propagate from the output to the input of an initially full FIFO is defined as the bubble-back time.

The maximum rate at which data can be passed through the FIFO (called the throughput) is limited by the fall-through time when it is empty (or near empty) and by the bubble-back time when it is full (or near full).

The conventional definitions of fall-through and bubble-back do not apply to the CY7C408A and CY7C409A FIFOs because the data is not physically propagated through the memory. The read and write pointers are incremented instead of moving the data. However, the parameter is specified because it does represent the worst-case propagation delay for the control signals. That is, the time required to increment the write pointer and propagate a signal from the SI input to the OR output of an empty FIFO or the time required to increment the read pointer and propagate a signal from the SO input to the IR output of a full FIFO.

Resetting the FIFO

Upon power-up, the FIFO must be reset with a master reset ($\overline{MR}$) signal. This causes the device to enter the empty condition, which is signified by the OR signal being LOW at the same time that the IR signal is HIGH. In this condition, the data outputs (DO_0 – DO_8) will be LOW. The AFE flag will be HIGH and the HF flag will be LOW.

Shifting Data Into the FIFO

The availability of an empty location is indicated by the HIGH state of the input ready (IR) signal. When IR is HIGH a LOW to HIGH transition on the shift in (SI) pin will clock the data on the DI_0 - DI_8 inputs into the FIFO. Data propagates through the device at the falling edge of SI.

The IR output will then go LOW, indicating that the data has been sampled. The HIGH-to-LOW transition of the SI signal initiates the LOW-to-HIGH transition of the IR signal if the FIFO is not full. If the FIFO is full, IR will remain LOW.

Shifting Data Out of the FIFO

The availability of data at the outputs of the FIFO is indicated by the HIGH state of the output ready (OR) signal. After the FIFO is reset all data outputs (DO_0 – DO_8) will be in the LOW state. As long as the FIFO remains empty, the OR signal will be LOW and all SO pulses applied to it will be ignored. After data is shifted into the FIFO, the OR signal will go HIGH. The external control logic (designed by the user) should use the HIGH state of the OR signal to generate a SO pulse. The data outputs of the FIFO should be sampled with edge-sensitive type D flip-flops (or equivalent), using the SO signal as the clock input to the flip-flop.

AFE and HF Flags

Two flags, almost full/almost empty (AFE) and half full (HF), describe how many words are stored in the FIFO. AFE is HIGH when there are 8 or fewer or 56 or more words stored in the FIFO. Otherwise the AFE flag is LOW. HF is HIGH when there are 32 or more words stored in the FIFO, otherwise the HF flag is LOW. Flag transitions occur relative to the falling edges of SI and SO (*Figures 1* and *2*).

Due to the asynchronous nature of the SI and SO signals, it is possible to encounter specific timing relationships which may cause short pulses on the AFE and HF flags. These pulses are entirely due to the dynamic relationship of the SI and SO signals. The flags, however, will always settle to their correct state after the appropriate delay (t_{DHAFE}, t_{DLAFE}, t_{DHHF}, or t_{DLHF}). Therefore, use of level-sensitive rather than edge-sensitive flag detection devices is recommended to avoid false flag encoding.

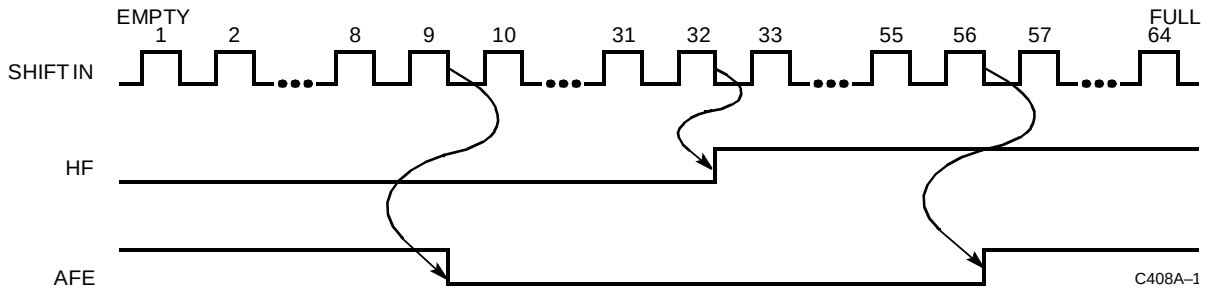

Figure 1. Shifting Words In.

Possible Minimum Pulse Width Violation at the Boundary Conditions

If the handshaking signals IR and OR are not properly used to generate the SI and SO signals, it is possible to violate the minimum (effective) SI and SO positive pulse widths at the full and empty boundaries.

Cascading the 7C408/9A-35 Above 25 MHz

First, the capacity of N cascaded FIFOs is decreased from N $\times$ 64 to (N $\times$ 63) + 1.

If cascaded FIFOs are to be operated with an external clock rate greater than 25 MHz, the interface IR signal must be inverted before being fed back to the interface SO pin (*Figure 3*). Two things should be noted when this configuration is implemented.

Secondly, the frequency at the cascade interface is less than the 35 MHz rate at which the external clocks may operate. Therefore, the first device has its data shifted in faster than it is shifted out, and eventually this device becomes momentarily full. When this occurs, the maximum sustainable external clock frequency changes from 35 MHz to the cascade interface frequency.[28]

When data packets[29] are transmitted, this phenomenon does not occur unless more than three FIFOs are depth cascaded. For example, if two FIFOs are cascaded, a packet of 127 (=2 $\times$ 63 + 1) words may be shifted in at up to 35 MHz and then the entire packet may be shifted out at up to 35 MHz.

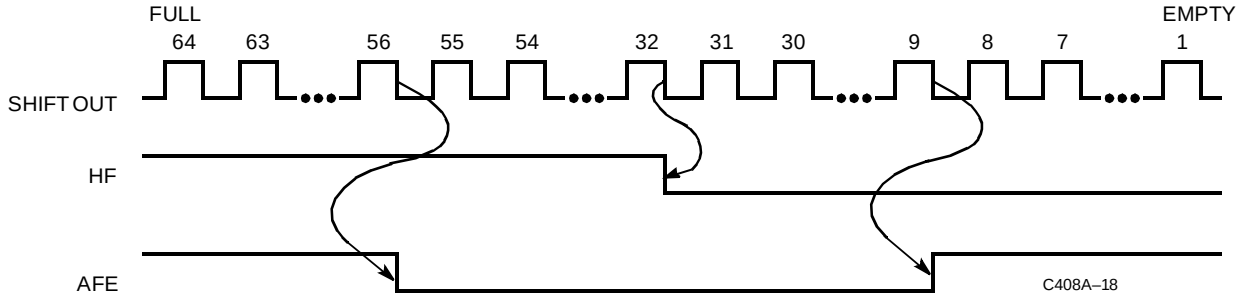

Figure 2. Shifting Words Out.

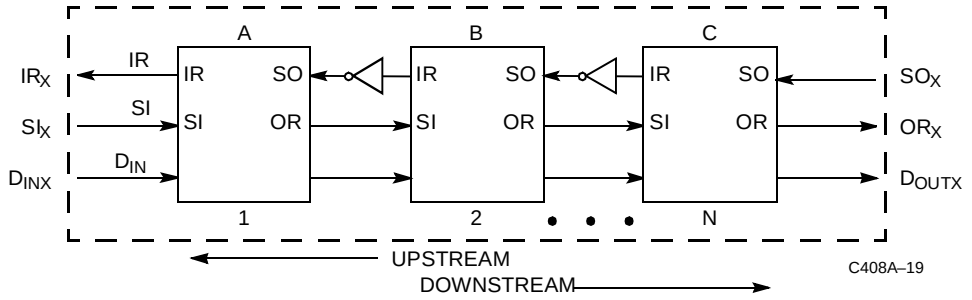

Figure 3. Cascaded Configuration Above 25 MHz.

128 x 9 Configuration

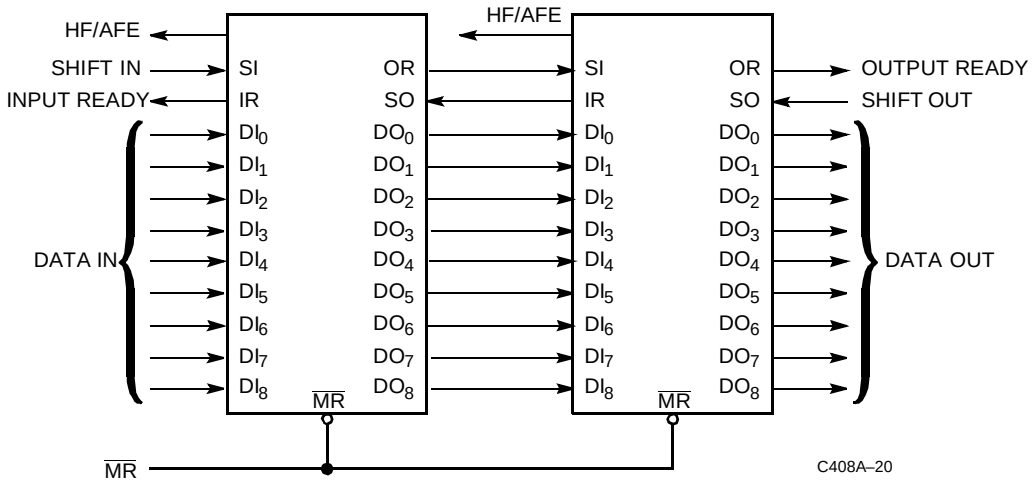

Figure 4. Cascaded Configuration at or below 25 MHz [22,23,24,25,26].

192 x 27 Configuration

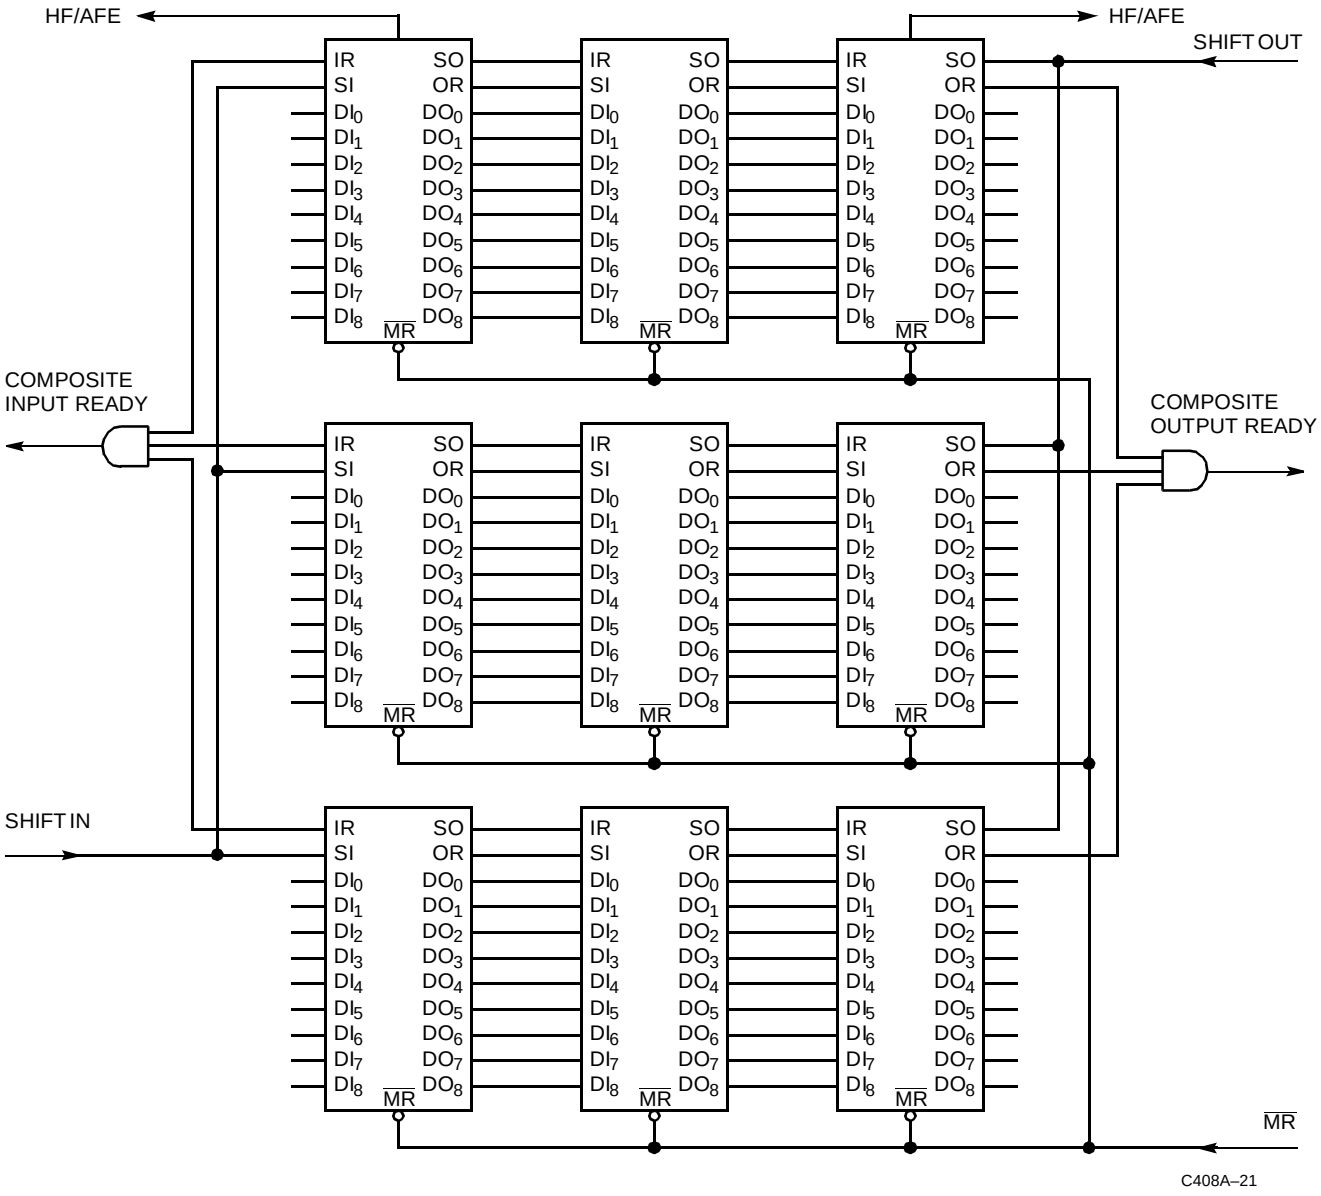

Figure 5. Depth and Width Expansion[23,24,25,26,27].

Notes:

22. FIFOs can be easily cascaded to any desired depth. The handshaking and associated timing between the FIFOs are handled by the inherent timing of the devices.
23. When the memory is empty the last word read will remain on the outputs until the master reset is strobed or a new data word falls through to the output.
24. When the output data changes as a result of a pulse on SO, the OR signal always goes LOW before there is any change in output data and stays LOW until the new data has appeared on the outputs. Anytime OR is HIGH, there is valid stable data on the outputs.
25. If SO is held HIGH while the memory is empty and a word is written into the input, that word will fall through the memory to the output. OR will go HIGH for one internal cycle (at least t_{POR}) and then go back LOW again. The stored word will remain on the outputs. If more words are written into the FIFO, they will line up behind the first word and will not appear on the outputs until SO has been brought LOW.
26. When the master reset is brought LOW, the outputs are cleared to LOW, IR goes HIGH, and OR goes LOW.
27. FIFOs are expandable in depth and width. However, in forming wider words, two external gates are required to generate composite input ready and output ready flags. This need is due to the variation of delays of the FIFOs
28. Because the data throughput in the cascade interface is dependent on the inverter delay, it is recommended that the fastest available inverter be used.
29. Transmission of data packets assumes that up to the maximum cumulative capacity of the FIFOs is shifted in without simultaneous shift out clock occurring. The complement of this holds when data is shifted out as a packet.

If data is to be shifted out simultaneously with the data being shifted in, the concept of "virtual capacity" is introduced. Virtual capacity is simply how large a packet of data can be shifted in at a fixed frequency, e.g., 35 MHz, simultaneously with data being shifted out at any given frequency. *Figure 6* is a graph of packet size[30] vs. shift out frequency (f_{SOx}) for two different values of shift in frequency (f_{SIx}) when two FIFOs are cascaded.

The exact complement of this occurs if the FIFOs initially contain data and a high shift out frequency is to be maintained, i.e., a 35 MHz f_{SOx} can be sustained when reading data packets from devices cascaded two or three deep.[31] If data is shifted in simultaneously, *Figure 6* applies with f_{SIx} and f_{SOx} interchanged.

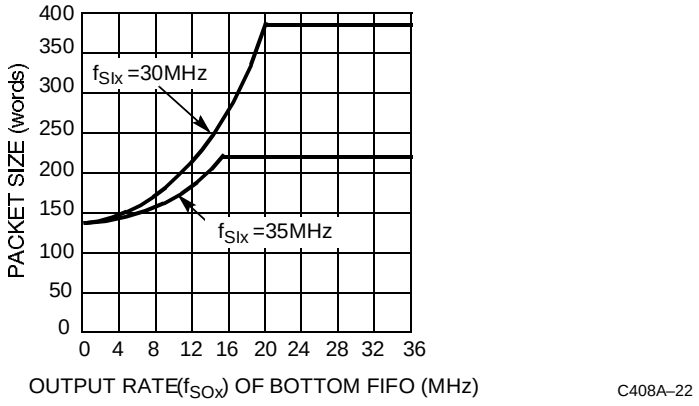

Figure 6. Virtual Capacity vs. Output Rate for Two FIFOs Cascaded Using an Inverter.

Notes:
30. These are typical packet sizes using an inverter whose delay is 4 ns.
31. Only devices with the same speed grade are specified to cascade together.
