### 23.17.31 CAN RX IO Control Register (DCAN RIOC)

The CAN\_RX pin of the DCAN module can be used as general-purpose IO pin if CAN function is not needed.

**NOTE:** The values of the IO Control registers are writable only if Init bit of CAN Control Register is set.

The OD, Func, and Dir bits of the CAN RX IO Control register are forced to certain values when Init bit of CAN Control Register is reset, see bit description.

## ***Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)***

---

---

This chapter provides the specifications for a 16-bit configurable synchronous multi-buffered multi-pin serial peripheral interface (MibSPI). This chapter also provides the specifications for MibSPI with Parallel Pin Option (MibSPIP). The MibSPI is a programmable-length shift register used for high-speed communication between external peripherals or other microcontrollers.

Throughout this chapter, all references to SPI also apply to MibSPI/MibSPIP, unless otherwise noted.

---

**NOTE:** This chapter describes a superset implementation of the MibSPI/SPI modules that includes features and functionality that may not be available on some devices. Device-specific content that should be determined by referencing the datasheet includes DMA functionality, MibSPI RAM size, number of transfer groups, number of chip selects, parallel mode support, and availability of 5-pin operation (SPIENA).

---

## 24.1 Overview

The MibSPI/MibSPIP is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (2 to 16 bits) to be shifted in and out of the device at a programmed bit-transfer rate. Typical applications for the SPI include interfacing to external peripherals, such as I/Os, memories, display drivers, and analog-to-digital converters.

The SPI has the following attributes:

- 16-bit shift register
- Receive buffer register
- 11-bit baud clock generator
- Serial clock (SPICLK) pin
- 1 SPISOMI/SPISIMO pin for data transfer, with programmable pin direction
- SPI enable ( $\overline{\text{SPIENA}}$ ) pin
- Up to 6 slave chip select ( $\overline{\text{SPICS}}$ ) pins
- SPICLK can be internally-generated (and driven) or received from an external clock source
- Each word transferred can have a unique format
- SPI pins can be used as functional or digital Input/Output pins (GIOs)

---

**NOTE:** SIMO - Slave In Master Out Pin  
SOMI - Slave Out Master In Pin  
SPICS - SPI Chip Select Pin  
SPIENA - SPI Enable Pin

---

### 24.1.1 Word Format Options

Each word transferred can have a unique format. Several format characteristics are programmable for each word transferred:

- SPICLK frequency
- Character length (2 to 16 bits)
- Phase (with and without delay)
- Polarity (high or low)
- Parity enabled/disabled
- Chip Select(CS) timers for setup and hold
- Shift direction (Most-Significant Bit (MSB) first or Least-Significant Bit (LSB) first)
- Multi-pin parallel modes

### 24.1.2 Multi-buffering (Mib) Support

The MibSPI has a programmable buffer memory that enables programmed transmission to be completed without CPU intervention. The buffers are combined in different Transfer Groups (TGs) that can be triggered by external events (timers, Input/Output activity, and so on) or by the internal tick counter. The internal tick counter supports periodic trigger events. Each buffer of the MibSPI can be associated with different DMA channels in different TGs, allowing the user to move data between internal memory and an external slave with minimal CPU interaction.

### 24.1.2.1 Multi-buffer Mode

Multi-buffer Mode is an extension to the SPI. In multi-buffer mode, many extended features are configurable:

- Number of buffers for each peripheral (or data source/destination, up to 128 buffers supported) or group (up to 8 groupings)
- Triggers for each groups, trigger types, trigger sources for individual groups (14 external trigger sources and 1 internal trigger source supported)
- Memory fault detection via an internal parity circuit
- Number of DMA-controlled buffers and number of DMA request channels (up to 8 for each of transmit and receive)
- Number of DMA transfers for each buffer (up to 65536 words for up to 8 buffers)
- Uninterrupted DMA buffer transfer (NOBREAK buffer)

### 24.1.2.2 Compatibility Mode

Compatibility Mode of the MibSPI makes it behave exactly like a standard platform SPI module and ensures full compatibility with other SPIs. All features in compatibility mode of the MibSPI are directly applicable to a SPI. Multi-buffer Mode features are not available in Compatibility Mode.

---

**NOTE:** The SPIDAT0 register is not accessible in the multi-buffer mode of MibSPI. It is only accessible in compatibility mode.

---

### 24.1.3 Transmission Lock (Multi-Buffer Mode Master Only)

Some slave devices require transmission of a command followed by data. In this case the SPI transaction should not be interrupted by another group transfer. The LOCK bit within each buffer allows a consecutive transfer to happen without being interrupted by another higher-priority group transfer.

## 24.2 Operating Modes

The SPI can be configured via software to operate as either a master or a slave. The MASTER bit (SPIGCR1[0]) selects the configuration of the SPISIMO and SPISOMI pins. CLKMOD bit (SPIGCR1[1]) determines whether an internal or external clock source will be used.

The slave chip select ( $\overline{\text{SPICS}}$ ) pins are used when communicating with multiple slave devices or, with a single slave, to delimit messages containing a leading register address. When a write occurs to SPIDAT1 in master mode, the  $\overline{\text{SPICS}}$  pins are automatically driven to select the specified slave.

Handshaking mechanism, provided by the  $\overline{\text{SPIENA}}$  pin, enables a slave SPI to delay the generation of the clock signal supplied by the master if it is not prepared for the next exchange of data.

---

**NOTE:** If in the slave mode of operation and configured in either 3-pin or 4-pin (without  $\overline{\text{SPIENA}}$ ) modes, there must be a minimum of 8 VCLK cycles of delay between the last SPICLK and the start of the SPICLK for the next buffer transmit. In general, this equates to a VCLK/SPICLK ratio of  $\leq 16$  requiring a minimum of 1 SPICLK delay between transmissions.

---

### 24.2.1 Pin Configurations

The SPI supports data connections as shown in [Table 24-1](#).

**NOTE:**

1. When the SPICS signals are disabled, the chip select field in the transmit data is not used.
2. When the  $\overline{\text{SPIENA}}$  signal is disabled, the  $\overline{\text{SPIENA}}$  pin is ignored in master mode, and not driven as part of the SPI transaction in slave mode.

**Table 24-1. Pin Configurations**

| Pin                        | Master Mode                                                   |                                                                                                      | Slave Mode                                                    |                                                                                                     |
|----------------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|

### 24.2.2 Data Handling

[Figure 24-1](#) shows the SPI transaction hardware. TXBUF and RXBUF are internal buffers that are intended to improve the overall throughput of data transfer. TXBUF is a transmit buffer, while RXBUF is a receive buffer.

#### 24.2.2.1 Data Sequencing when SPIDAT0 or SPIDAT1 is Written

- If both the TX shift register and TXBUF are empty, then the data is directly copied to the TX shift register. For devices with DMA, if DMA is enabled, a transmit DMA request (TX\_DMA\_REQ) is generated to cause the next word to be fetched. If transmit interrupts are enabled, a transmitter-empty interrupt is generated.
- If the TX shift register is already full or is in the process of shifting and if TXBUF is empty then the data written to SPIDAT0 / SPIDAT1 is copied to TXBUF and TXFULL flag is set to 1 at the same time.
- When a shift operation is complete, data from the TXBUF (if it is full) is copied into TX shift register and the TXFULL flag is cleared to 0 to indicate that next data can be fetched. A transmit DMA request (if enabled) or a transmitter-empty interrupt (if enabled) is generated at the same time.

#### 24.2.2.2 Data Sequencing when All Bits Shifted into RXSHIFT Register

- If both SPIBUF and RXBUF are empty, the received data in RX shift register is directly copied into SPIBUF and the receive DMA request (if enabled) is generated and the receive-interrupt (if enabled) is generated. The RXEMPTY flag in SPIBUF is cleared at the same time.
- If SPIBUF is already full at the end of receive completion, the RX shift register contents is copied to RXBUF. A receive DMA request is generated, if enabled. The receive complete interrupt line remains high.
- If SPIBUF is read by the CPU or DMA and if RXBUF is full, then the contents of RXBUF are copied to SPIBUF as soon as SPIBUF is read. RXEMPTY flag remains cleared, indicating that SPIBUF is still full.
- If both SPIBUF and RXBUF are full, then RXBUF will be overwritten and the RXOVR interrupt flag is set and an interrupt is generated, if enabled.

Figure 24-1. SPI Functional Logic Diagram

- 1 This is a representative diagram, which shows three-pin mode hardware.
- 2 TXBUF, RXBUF, and SHIFT\_REGISTER are user-invisible registers.
- 3 SPIDAT0 and SPIDAT1 are user-visible, and are physically mapped to the contents of TXBUF.
- 4 SPISIMO, SPISOMI, SPICLK pin directions depend on the Master or Slave Mode.

### 24.2.2.3 Three-Pin Mode

In master mode configuration (MASTER = 1 and CLKMOD = 1), the SPI provides the serial clock on the SPICLK pin. Data is transmitted on the SPISIMO pin and received on the SPISOMI pin (see [Figure 24-2](#)).

Data written to the shift register (SPIDAT0 / SPIDAT1) initiates data transmission on the SPISIMO pin, MSB first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB of the SPIDAT0 register. When the selected number of bits have been transmitted, the received data in the shift register is transferred to the SPIBUF register for the CPU to read. Data is stored right-justified in SPIBUF.

See [Section 24.2.2.1](#) and [Section 24.2.2.2](#) for details about the data handling for transmit and receive operations.

In slave mode configuration (MASTER = 0 and CLKMOD = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock.

Data written to the SPIDAT0 or SPIDAT1 register is transmitted to the network when the SPICLK signal is received from the network master. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts data on the SPISIMO pin into the RX shift register. If data is to be transmitted by the slave simultaneously, it must be written to the SPIDAT0 or SPIDAT1 register before the beginning of the SPICLK signal.

**Figure 24-2. SPI Three-Pin Operation**

### 24.2.3 Operation with $\overline{\text{SPICS}}$

In master mode, each chip select signal is used to select a specific slave. In slave mode, the chip select signal is used to enable and disable the transfer. Chip-select functionality is enabled by setting one of the  $\overline{\text{SPICS}}$  pins as a chip select. It is disabled by setting all  $\overline{\text{SPICS}}$  pins as GPIOs in SPIPC0.

#### 24.2.3.1 Multiple Chip Selects

The  $\overline{\text{SPICS}}$  pins that are used must be configured as functional pins in the SPIPC0 register. The default pattern to be put on the  $\overline{\text{SPICS}}$  when all the slaves are deactivated is set in the SPIDEF register. This pattern allows different slaves with different chip-select polarity to be activated by the SPI.

The master-mode SPI is capable of driving either 0 or 1 as the active value for any  $\overline{\text{SPICS}}$  output pin. The drive state for the  $\overline{\text{SPICS}}$  pins is controlled by the CSNR field of SPIDAT1. The pattern that is driven will select the slave to which the transmission is dedicated.

In slave mode, the SPI can only be selected by an active value of 0 on any of its selected  $\overline{\text{SPICS}}$  input pins.

Figure 24-3. Operation with  $\overline{\text{SPICS}}$

### 24.2.4 Operation with $\overline{\text{SPIENA}}$

The  $\overline{\text{SPIENA}}$  operates as a WAIT signal pin. For both the slave and the master, the  $\overline{\text{SPIENA}}$  pin must be configured to be functional (SPIPC0[8] = 1). In this mode, an active-low signal from the slave on the  $\overline{\text{SPIENA}}$  pin allows the master SPI to drive the clock pulse stream. A high signal tells the master to hold the clock signal (and delay SPI activity).

If the  $\overline{\text{SPIENA}}$  pin is in high-impedance mode (ENABLE\_HIGHZ = 1), the slave will put  $\overline{\text{SPIENA}}$  into the high-impedance once it completes receiving a new character. If the  $\overline{\text{SPIENA}}$  pin is in push-pull mode (ENABLE\_HIGHZ = 0), the slave will drive  $\overline{\text{SPIENA}}$  to 1 once it completes receiving a new character. The slave will drive  $\overline{\text{SPIENA}}$  low again for the next word to transfer, after new data is written to the slave TX shift register.

In master mode (CLKMOD = 1), if the  $\overline{\text{SPIENA}}$  pin is configured as functional, then the pin acts as an input pin. If configured as a slave SPI and as functional, the  $\overline{\text{SPIENA}}$  pin acts as an output pin.

**NOTE:** During a transfer, if a slave-mode SPI detects a deassertion of its chip select before its internal character length counter overflows, then it places SPISOMI and  $\overline{\text{SPIENA}}$  (if ENABLE\_HIGHZ bit is set to 1) in high-impedance mode. Once this condition has occurred, if a SPICLK edge is detected while the chip select is deasserted, then the SPI stops that transfer and sets an DLENERR error flag and generates an interrupt (if enabled).

**Figure 24-4. Operation with  $\overline{\text{SPIENA}}$**

## 24.2.5 Five-Pin Operation (Hardware Handshaking)

Five-pin operation combines the functionality of three-pin mode, plus the enable pin and one or more chip select pins. The result is full hardware handshaking. To use this mode, both the  $\overline{\text{SPIENA}}$  pin and the required number of  $\overline{\text{SPICS}}$  pins must be configured as functional pins.

If the  $\overline{\text{SPIENA}}$  pin is in high-impedance mode ( $\text{ENABLE\_HIGHZ} = 1$ ), the slave SPI will put this signal into the high-impedance state by default. The slave will drive the signal  $\overline{\text{SPIENA}}$  low when new data is written to the slave shift register and the slave has been selected by the master ( $\overline{\text{SPICS}}$  is low).

If the  $\overline{\text{SPIENA}}$  pin is in push-pull mode ( $\text{ENABLE\_HIGHZ} = 0$ ), the slave SPI drives this pin high by default when it is in functional mode. The slave SPI will drive the  $\overline{\text{SPIENA}}$  signal low when new data is written to the slave shift register ( $\text{SPIDAT0}/\text{SPIDAT1}$ ) and the slave is selected by the master ( $\overline{\text{SPICS}}$  is low). If the slave is deselected by the master ( $\overline{\text{SPICS}}$  goes high), the slave  $\overline{\text{SPIENA}}$  signal is driven high.

**NOTE:** Push-pull mode of the  $\overline{\text{SPIENA}}$  pin can be used only when there is a single slave in the system. When multiple SPI slave devices are connected to the common  $\overline{\text{SPIENA}}$  pin, all of the slaves should configure their  $\overline{\text{SPIENA}}$  pins in high-impedance mode.

In master mode, if the  $\overline{\text{SPICS}}$  pins are configured as functional pins, then the pins will be in output mode. A write to the master's  $\text{SPIDAT1}/\text{SPIDAT0}$  register will automatically drive the  $\overline{\text{SPICS}}$  signals low. The master will drive the  $\overline{\text{SPICS}}$  signals high again after completing the transfer of the bits of the data.

In slave mode ( $\text{CLKMOD} = 0$ ), the  $\overline{\text{SPICS}}$  pins act as SPI functional inputs.

Figure 24-5. SPI Five-Pin Option with  $\overline{\text{SPIENA}}$  and  $\overline{\text{SPICS}}$

## 24.2.6 Data Formats

To support multiple different types of slaves in one SPI network, four independent data word formats are implemented that allow configuration of individual data word length, polarity, phase, and bit rate. Each word transmitted can select which data format to use via the bits DFSEL[1:0] in its control field from one of the four data word formats. Same data format can be supported on multiple chip selects.

Data formats 0, 1, 2, and 3 can be configured through SPIFMTx control registers.

Each SPI data format includes the standard SPI data format with enhanced features:

- Individually-configurable shift direction can be used to select MSB first or LSB first, whereas the position of the MSB depends on the configured data word length.
- Receive data is automatically right-aligned, independent of shift direction and data word length. Transmit data has to be written right-aligned into the SPI and the internal shift register will transmit according to the selected shift direction and data word length for correct transfer.
- To increase fault detection of data transmission and reception, an odd or even parity bit can be added at the end of a data word. The parity generator can be enabled or disabled individually for each data format. If a received parity bit does not match with the locally calculated parity bit, the parity error flag (PARITYERR) is set and an interrupt is asserted (if enabled).

Since the master-mode SPI can drive two consecutive accesses to the same slave, an 8-bit delay counter is available to satisfy the delay time for data to be refreshed in the accessed slave. The delay counter can be programmed as part of the data format.

CHARLEN[4:0] specifies the number of bits (2 to 16) in the data word. The CHARLEN[4:0] value directs the state control logic to count the number of bits received or transmitted to determine when a complete word is transferred.

Data word length **must** be programmed to the same length for both the **master** and the **slave**. However, when chip selects are used, there may be multiple targets with different lengths in the system.

---

**NOTE:** Data must be right-justified when it is written to the SPI for transmission irrespective of its character length or word length.

---

Figure 24-6 shows how a 12-bit word (0xEC9) needs to be written to the transmit buffer to be transmitted correctly.

**Figure 24-6. Format for Transmitting an 12-Bit Word**

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| x   | x   | x   | x   | 1   | 1   | 1  | 0  | 1  | 1  | 0  | 0  | 1  | 0  | 0  | 1  |

---

**NOTE:** The received data is always stored right-justified regardless of the character length or direction of shifting and is padded with leading 0s when the character length is less than 16 bits.

---

Figure 24-7 shows how a 10-bit word (0x0A2) is stored in the buffer once it is received.

**Figure 24-7. Format for Receiving an 10-Bit Word**

| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 1  | 0  |

## 24.2.7 Clocking Modes

**SPICLK** may operate in four different modes, depending on the choice of phase (delay/no delay) and the polarity (rising edge/falling edge) of the clock.

The data input and output edges depend on the values of both **POLARITY** and **PHASE** as shown in [Table 24-2](#).

**Table 24-2. Clocking Modes**

| POLARITY | PHASE | Action                                                                                                                                                     |
|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0        | 0     | Data is output on the rising edge of SPICLK. Input data is latched on the falling edge.                                                                    |
| 0        | 1     | Data is output one half-cycle before the first rising edge of SPICLK and on subsequent falling edges. Input data is latched on the rising edge of SPICLK.  |
| 1        | 0     | Data is output on the falling edge of SPICLK. Input data is latched on the rising edge.                                                                    |
| 1        | 1     | Data is output one half-cycle before the first falling edge of SPICLK and on subsequent rising edges. Input data is latched on the falling edge of SPICLK. |

[Figure 24-8](#) to [Figure 24-11](#) illustrate the four possible configurations of **SPICLK** corresponding to each mode. Having four signal options allows the SPI to interface with many different types of serial devices.

**Figure 24-8. Clock Mode with Polarity = 0 and Phase = 0**

Data is output on the rising edge of SPICLK.  
Input data is latched on the falling edge of SPICLK.

**Figure 24-9. Clock Mode with Polarity = 0 and Phase = 1**

Data is output one-half cycle before the first rising edge of SPICLK and on subsequent falling edges of SPICLK  
Input data is latched on the rising edge of SPICLK

**Figure 24-10. Clock Mode with Polarity = 1 and Phase = 0**

Data is output on the falling edge of SPICLK.  
Input data is latched on the rising edge of SPICLK.

**Figure 24-11. Clock Mode with Polarity = 1 and Phase = 1**

Data is output one-half cycle before the first falling edge of SPICLK and on the subsequent rising edges of SPICLK.  
Input data is latched on the falling edge of SPICLK.

## 24.2.8 Data Transfer Example

Figure 24-12 illustrates a SPI data transfer between two devices using a character length of five bits.

**Figure 24-12. Five Bits per Character (5-Pin Option)**

### 24.2.9 Decoded and Encoded Chip Select (Master Only)

In this device, the SPI can connect to up to 6 individual slave devices using chip-selects by routing one wire to each slave. The 6 chip selects in the control field are directly connected to the 6 pins. The default value of each chip select (not active) can be configured via the register CSDEF. During a transmission, the value of the chip select control field (CSNR) of the SPIDAT1 register (SPIDAT1) is driven on the SPICS pins. When the transmission finishes, the default chip-select value (defined by the CSDEF register) is put on the SPICS pins.

The SPI can support more than 6 slaves by using encoded chip selects. To connect the SPI with encoded slaves devices, the CSNR field allows multiple active SPICS pins at the same time, which enables encoded chip selects from 0 to 16. To use encoded chip selects, all 6 chip select lines have to be connected to each slave device and each slave needs to have a unique chip-select address. The CSDEF register is used to provide the address at which slaves devices are all de-selected.

Users can combine decoded and encoded chip selects. For example,  $n$  SPICS pins can be used for encoding an  $n$ -bit address and the remaining pins can be connected to decoded-mode slaves.

### 24.2.10 Variable Chip Select Setup and Hold Timing (Master Only)

In order to support slow slave devices, a delay counter can be configured to delay data transmission after the chip select is activated. A second delay counter can be configured to delay the chip select deactivation after the last data bit is transferred. Both delay counters are clocked with the peripheral clock (VCLK).

If a particular data format specifically does not require these additional set-up or hold times for the chip select pins, then they can be disabled in the corresponding SPIFMTx register.

### 24.2.11 Hold Chip-Select Active

Some slave devices require the chip select signal to be held continuously active during several consecutive data word transfers. Other slave devices require the chip select signal to be deactivated between consecutive data word transfers.

CSHOLD is programmable in both master and slave modes of the multi-buffer mode of SPI. However, the meaning of CSHOLD in master mode and slave mode are different.

---

**NOTE:** If the CSHOLD bit is set within the current data control field, the programmed hold time and the following programmed set-up time will not be applied between transactions.

---

#### 24.2.11.1 CSHOLD Bit in Master Mode

Each word in a master-mode SPI can be individually initialized for one of the two modes via the CSHOLD bit in its control field.

If the CSHOLD bit is set in the control field of a word, the chip select signal will not be deactivated until the next control field is loaded with new chip select information. Since the chip-select is maintained active between two transfers, the chip-select hold delay (T2CDELAY) is not applied at the end of the current transaction, and the chip-select set-up time delay (C2TDELAY) is not applied as well at the beginning of the following transaction. However, the wait delay (WDELAY) will be still applied between the two transactions, if the WDEL bit is set within the control field.

Figure 24-13 shows the SPI pins when a master-mode SPI transfers a word that has its CSHOLD bit set. The chip-select pins will not be deasserted after the completion of this word. If the next word to transmit has the same chip-select number (CSNR) value, the chip select pins will be maintained until the completion of the second word, regardless of whether the CSHOLD bit is set or not.

**Figure 24-13. Typical Diagram when a Buffer in Master is in CSHOLD Mode (SPI-SPI)**

#### 24.2.11.2 CSHOLD Bit in Slave Mode (Multi-buffered Mode)

If the CSHOLD bit in a buffer is set to 1, then the MibSPI does not wait for the  $\overline{\text{SPICS}}$  pins to be deasserted at the end of the shift operation to copy the received data to the receive RAM. With this feature, it is possible for a slave in multi-buffer mode to do multiple data transfers without requiring the  $\overline{\text{SPICS}}$  pins to be deasserted between two buffer transfers.

If the CSHOLD bit in a buffer is cleared to 0 in a slave MibSPI, even after the shift operation is done, the MibSPI waits until the  $\overline{\text{SPICS}}$  pin (if functional) is deasserted to copy the received data to the RXRAM.

If the CSHOLD bit is maintained as 0 across all the buffers, then the slave in multi-buffer mode requires its  $\overline{\text{SPICS}}$  pins to be deasserted between any two buffer transfers; otherwise, the Slave SPI will be unable to respond to the next data transfer.

**NOTE:** In compatibility mode, the slave does not require the  $\overline{\text{SPICS}}$  pin to be deasserted between two buffer transfers. The CSHOLD bit of the slave will be ignored in compatibility mode.

#### 24.2.12 Detection of Slave Desynchronization (Master Only)

When a slave supports generation of an enable signal (ENA), desynchronization can be detected. With the enable signal a slave indicates to the master that it is ready to exchange data. A desynchronization can occur if one or more clock edges are missed by the slave. In this case, the slave may block the SOMI line until it detects clock edges corresponding to the next data word. This would corrupt the data word of the desynchronized slave and the consecutive data word. A configurable 8-bit time-out counter (T2EDELAY), which is clocked with SPICLK, is implemented to detect this slave malfunction. After the transmission has finished (end of last bit transferred: either last data bit or parity bit) the counter is started. If the ENA signal generated by the slave does not become inactive before the counter overflows, the DESYNC flag is set and an interrupt is asserted (if enabled).

---

**NOTE: Inconsistency of Desynchronization Flag in Compatibility Mode MibSPI**

Because of the nature of this error, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is due to the fact that receive completion flag/interrupt will be generated when the buffer transfer is completed. But desync will be detected after the buffer transfer is completed. So, if VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. This inconsistency in the desync flag is valid only in compatibility mode of MibSPI. In multi-buffer mode, the desync flag is always assured to be for the current buffer.

---

### 24.2.13 ENA Signal Time-Out (Master Only)

The SPI in master mode waits for the hardware handshake signal (ENA) coming from the addressed slave before performing a data transfer. To avoid stalling the SPI by a non-responsive slave device, a time-out value can be configured using C2EDELAY. If the time-out counter overflows before an active ENA signal is sampled, the TIMEOUT flag in the status register SPIFLG is set and the TIMEOUT flag in the status field of the corresponding buffer is set.

---

**NOTE:** When the chip select signal becomes active, no breaks in transmission are allowed. The next arbitration is performed while waiting for the time-out to occur.

---

### 24.2.14 Data-Length Error

A SPI can generate an error flag by detecting any mismatch in length of received or transmitted data and the programmed character length under certain conditions.

**Data-Length Error in Master Mode:** During a data transfer, if the SPI detects a de-assertion of the  $\overline{\text{SPIENA}}$  pin (by the slave) while the character counter is not overflowed, then an error flag is set to indicate a data-length error. This can be caused by a slave receiving extra clocks (for example, due to noise on the SPICLK line).

---

**NOTE:** In a master mode SPI, the data length error will be generated only if the  $\overline{\text{SPIENA}}$  pin is enabled as a functional pin.

---

**Data-Length Error in Slave Mode:** During a transfer, if the SPI detects a de-assertion of the  $\overline{\text{SPICS}}$  pin before its character length counter overflows, then an error flag is set to indicate a data-length error. This situation can arise if the slave SPI misses one or more SPICLK pulses from the master. This error in slave mode implies that both the transmitted and received data were not complete.

---

**NOTE:** In a slave mode SPI, the data-length error flag will be generated only if at least one of the  $\overline{\text{SPICS}}$  pins are configured as functional, and are being used for selecting the slave.

---

### 24.2.15 Parallel Mode (Multiple SIMO/SOMI Support, not available on all devices)

In order to increase throughput, the parallel mode of the SPI enables the module to send data over more than one data line (parallel 2, 4, or 8). When parallel mode is used, the data length must be set as 16 bits. Only module MIBSPIP5 supports Parallel Mode.

This feature increases throughput by 2 for 2 pins, by 4 for 4 pins, or by 8 for 8 pins.

Parallel mode supports the following features:

- Scalable data lines (1, 2, 4, 8) per direction. (SOMI and SIMO lines)
- All clock schemes are supported (clock phase and polarity)
- Parity is supported. The parity bit will be transmitted on bit0 of the SIMO/SOMI lines. The receive parity is expected on bit0 of the SOMI/SIMO pins.

Parallel mode can be programmed using the PMODEx bits of SPIPMCTRL register. See [Section 24.9.25](#) for details about this register.

After reset the parallel mode selection bits are cleared (single SIMO/SOMI lines).

### 24.2.15.1 Parallel Mode Block Diagram

[Figure 24-14](#) and [Figure 24-15](#) show the parallel connections to the SPI shift register.

**Figure 24-14. Block Diagram Shift Register, MSB First**

**Figure 24-15. Block Diagram Shift Register, LSB First**

### 24.2.15.2 Parallel Mode Pin Mapping, MSB First

Table 24-3 and Table 24-4 describe the SOMI and SIMO pin mapping when the SPI is used in parallel mode (1, 2, 4, 8) pin mode, MSB first.

**NOTE:** MSB-first or LSB-first can be configured using the SHIFTDIRx bit of the SPIFMTx registers.

**Table 24-3. Pin Mapping for SIMO Pin with MSB First**

| Parallel Mode | Shift Register Bit | SIMO[7:0] |
|---------------|--------------------|-----------|
| 1             | 15                 | 0         |
| 2             | 15                 | 1         |
|               | 7                  | 0         |
| 4             | 15                 | 3         |
|               | 11                 | 2         |
|               | 7                  | 1         |
|               | 3                  | 0         |
| 8             | 15                 | 7         |
|               | 13                 | 6         |
|               | 11                 | 5         |
|               | 9                  | 4         |
|               | 7                  | 3         |
|               | 5                  | 2         |
|               | 3                  | 1         |
|               | 1                  | 0         |

**Table 24-4. Pin Mapping for SOMI Pin with MSB First**

| Parallel Mode | Shift Register Bit | SOMI[7:0] |
|---------------|--------------------|-----------|
| 1             | 0                  | 0         |
| 2             | 0                  | 0         |
|               | 8                  | 1         |
| 4             | 0                  | 0         |
|               | 4                  | 1         |
|               | 8                  | 2         |
|               | 12                 | 3         |
| 8             | 0                  | 0         |
|               | 2                  | 1         |
|               | 4                  | 2         |
|               | 6                  | 3         |
|               | 8                  | 4         |
|               | 10                 | 5         |
|               | 12                 | 6         |
|               | 14                 | 7         |

### 24.2.15.3 Parallel Mode Pin Mapping, MSB-First, LSB-First

Table 24-5 and Table 24-6 describe the SIMO and SOMI pin mapping when SPI is used in parallel mode (1, 2, 4, 8) pin mode, LSB first.

**Table 24-5. Pin Mapping for SIMO Pin with LSB First**

| Parallel Mode | Shift Register Bit | SIMO[7:0] |
|---------------|--------------------|-----------|
| 1             | 0                  | 0         |
| 2             | 8                  | 1         |
|               | 0                  | 0         |
| 4             | 12                 | 3         |
|               | 8                  | 2         |
|               | 4                  | 1         |
|               | 0                  | 0         |
| 8             | 14                 | 7         |
|               | 12                 | 6         |
|               | 10                 | 5         |
|               | 8                  | 4         |
|               | 6                  | 3         |
|               | 4                  | 2         |
|               | 2                  | 1         |
|               | 0                  | 0         |

**Table 24-6. Pin Mapping for SOMI Pin with LSB First**

| Parallel Mode | Shift Register Bit | SOMI[7:0] |
|---------------|--------------------|-----------|
| 1             | 15                 | 0         |
| 2             | 7                  | 0         |
|               | 15                 | 1         |
| 4             | 3                  | 0         |
|               | 7                  | 1         |
|               | 11                 | 2         |
|               | 15                 | 3         |
| 8             | 1                  | 0         |
|               | 3                  | 1         |
|               | 5                  | 2         |
|               | 7                  | 3         |
|               | 9                  | 4         |
|               | 11                 | 5         |
|               | 13                 | 6         |
|               | 15                 | 7         |

#### 24.2.15.4 2-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 2-data line mode (master mode) the shift register bits 15 and 7 will be connected to the pins SIMO[1] and SIMO[0], and the shift register bits 8 and 0 will be connected to the pins SOMI[1] and SOMI[0] or vice versa in slave mode. After writing to the SPIDAT0/SPIDAT1 register, the bits 15 and 7 will be output on SIMO[1] and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[1] and SOMI[0] will be latched to the shift register bits 8 and 0. The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. (SIMO[1] will shift the data out from bit 15 to 8, SIMO[0] will shift the data out from bit 7 to 0). After eight SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. [Figure 24-16](#) shows the clock /data diagram of the 2-data line mode. [Figure 24-17](#) shows the timing of a two-pin parallel transfer.

**Figure 24-16. 2-data Line Mode (Phase 0, Polarity 0)**

**Figure 24-17. Two-Pin Parallel Mode Timing Diagram (Phase 0, Polarity 0)**

#### 24.2.15.5 4-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 4-data line mode (master mode) the shift register bits 15, 11, 7, and 3 will be connected to the pins SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift register bits 12, 8, 4, and 0 will be connected to the pins SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode). After writing to SPIDAT1/SPIDAT0, the bits 15, 11, 7, and 3 will be output on SIMO[3], SIMO[2], SIMO[1], and SIMO[0] on the rising edge of SPICLK. With the falling clock edge of the SPICLK, the received data on SOMI[3], SOMI[2], SOMI[1] and SOMI[0] will be latched to shift register bits 12, 8, 4, and 0. The subsequent rising edge of SPICLK will shift data in the shift register by 1 bit to the left (SIMO[3] will shift the data out from bit 15 to 12, SIMO[2] will shift the data out from bit 11 to 8, SIMO[1] will shift the data out from bit 7 to 4, SIMO[0] will shift the data out from bit 3 to 0). After four SPICLK cycles, when the full data word is transferred, the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set.

Figure 24-18 shows the clock/data diagram of the four-data line mode. Figure 24-19, shows the timing diagram for four-data line mode.

Figure 24-18. 4-Data Line Mode (Phase 0, Polarity 0)

Figure 24-19. 4 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)

### 24.2.15.6 8-Data Line Mode (MSB First, Phase 0, Polarity 0)

In 8-data line mode (master mode) the shift register bits 15, 13, 11, 9, 7, 5 and 3 will be connected to the pins SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], and the shift-register bits 14, 12, 10, 8, 6, 4, and 0 will be connected to the pins SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] (or vice versa in slave mode).

After writing to SPIDAT0/SPIDAT1, the bits 15, 13, 11, 9, 7, 5, 3, and 1 will be output on SIMO[7], SIMO[6], SIMO[5], SIMO[4], SIMO[3], SIMO[2], SIMO[1], and SIMO[0], on the rising edge of SPICLK. On the falling clock edge of the SPICLK, the received data on SOMI[8], SOMI[7], SOMI[6], SOMI[5], SOMI[4], SOMI[3], SOMI[2], SOMI[1], and SOMI[0] will be latched to the shift register bits 14, 12, 10, 8, 6, 4, 2, and 0.

The subsequent rising edge of SPICLK will shift the data in the shift register by 1 bit to the left. After two SPICLK cycles, when the full data word is transferred the shift register (16 bits) is copied to the receive buffer, and the RXINT flag will be set. [Figure 24-20](#) shows the clock/data diagram of the 8-data line mode. [Figure 24-21](#) shows the pin timings for 8-data line mode.

**Figure 24-20. 8-data Line Mode (Phase 0, Polarity 0)**

#### NOTE: Parity Support

Using the parity support in parallel mode may seriously affect throughput. For an eight-line mode to transfer 16 bits of data, only two SPICLK pulses are enough. If parity is enabled, one extra SPICLK pulse will be used to transfer and receive the parity bit. Parity will be transmitted and received on the 0th line regardless of 1/2/4/8-line modes. During the parity bit transfer, other data bits are not valid.

**Figure 24-21. 8 Pins Parallel Mode Timing Diagram (Phase 0, Polarity 0)**

**NOTE:** Modulo Count Parallel Mode is not supported in this device.

### 24.2.16 Continuous Self-Test (Master/Slave)

During data transfer, the SPI compares its own internal transmit data with its transmit data on the bus. The sample point for the compare is at one-half SPI clock after transmit point. If the data on the bus does not match the expected value, the bit-error (BITERR) flag is set and an interrupt is asserted if enabled.

---

**NOTE:** The compare is made from the output pin using its input buffer.

---

### 24.2.17 Half Duplex Mode

SPI by protocol is Full Duplex in nature, which means simultaneous TX and RX operations happen on two separate data pins, SIMO and SOMI. However, it is possible to use SPI/MibSPI to do the TX-only operation (ignoring the RX data) and the RX-only operation (using dummy TX data and ignoring the TX pin). But this requires that both SOMI and SIMO lines are bonded out in a chip to be able to support both TX-only or RX-only features.

#### 24.2.17.1 Half Duplex Mode in Master

The Half Duplex Mode gives an additional flexibility to use the SIMO pin, which is normally used as a TX pin in Master mode, to work like an RX pin while the HDUPLEX\_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Master mode, the SIMO pin acts as an RX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

#### 24.2.17.2 Half Duplex Mode in Slave

In Half Duplex Slave mode, the SIMO pin, which is normally an RX pin, acts as a TX pin while the HDUPLEX\_ENAx bit in SPIFMTx register is set to 1. In Half Duplex Slave mode, the SIMO pin acts as a TX pin. Switching between Full Duplex and Half Duplex can be achieved using the SPIFMTx register being selected using the DFSEL bit of SPIDAT1 register or TXRAM locations.

## 24.3 Test Features

### 24.3.1 Internal Loop-Back Test Mode (Master Only)

The internal loop-back self-test mode can be utilized to test the SPI transmit and receive paths, including the shift registers, the SPI buffer registers, and the parity generator. In this mode the transmit signal is internally feedback to the receiver, whereas the SIMO, SOMI, and CLK pin are disconnected; that is, the transmitted data is internally transferred to the corresponding receive buffer while external signals remain unchanged.

This mode allows the CPU to write into the transmit buffer, and check that the receive buffer contains the correct transmit data. If an error occurs the corresponding error is set within the status field.

---

**NOTE:** This mode cannot be changed during transmission.

---

## 24.3.2 Input/Output Loopback Test Mode

Input/Output Loopback Test mode supports the testing of all Input/Output pins without the aid of an external interface. Loopback can be configured as either analog-loopback (loopback through the pin-level input/output buffers) or digital loopback (internal to the SPI module). With Input/Output Loopback, all functional features of the SPI can be tested. Transmit data is fed back through the receive-data line(s). See Figure 24-22 for a diagram of the types of feedback available. The IOLPBKTSTCR register defines all of the available control fields.

In loopback mode, it is also possible to induce various error conditions. See Section 24.9.43 for details of the register field controlling these features.

In Input/Output loopback test modes, even when the module is in slave mode, the SPICLK is generated internally. This SPICLK is used for all loopback-mode SPI transactions. Slave-mode features can be tested without the help of another master SPI, using the internally-generated SPICLK. Chip selects are also generated by the slave itself while it is in Input/Output loopback mode.

In Input/Output loopback test modes, if the module is in master mode, the  $\overline{\text{ENA}}$  signal is also generated by internal logic so that an external interface is not required.

### NOTE: Usage Guideline for Input/Output Loopback

Input/Output Loopback mode should be used with caution because, in some configurations, even the receive pins will be driven with transmit data. During testing, it should be ensured that none of the SPI pins are driven by any other device connected to them. Otherwise, if analog loopback is selected in I/O Loopback mode, then testing may damage the device.

**Figure 24-22. I/O Paths during I/O Loopback Modes**

This diagram is intended to illustrate loopback paths and therefore may omit some normal-mode paths.

### 24.3.2.1 Input/Output Loopback Mode Operation in Slave Mode

In multi-buffer slave mode, there are some additional requirements for using I/O loopback mode (IOLPBK). In multi-buffer slave mode, the chip-select pins are the triggers for various TGs. Enabling the IOLPBK mode by writing 0xA to the IOLPBTSTENA bits of the IOLPBKTSTCR register triggers TG0 by driving SPICS to 0. The actual number of chip selects can be programmed to have any or all of the SPICS pins as functional. All other configurations should be completed before enabling the IOLPBK mode in multi-buffer slave mode since it triggers TG0.

After the first buffer transfer is completed, the CSNR field of the current buffer is used to trigger the next buffer. So, if multiple TGs are desired to be tested, then the CSNR field of the final buffer in each TG should hold the number of the next TG to be triggered. As long as TG boundaries are well defined and are enabled, the completion of one TG will trigger the next TG.

To stop the transfer in multi-buffer slave mode in I/O Loopback configuration, either IOLPBK mode can be disabled by writing 0x5 to the IOLPBTSTENA bits or all of the TGs can be disabled.

## 24.4 General-Purpose I/O

All of the SPI pins may be programmed via the SPIPCx control registers to be either functional or general-purpose I/O pins.

If the SPI function is to be used, application software must ensure that at least the SPICLK pin and the SOMI and/or SIMO pins are configured as SPI functional pins, and not as GIO pins, or else the SPI state machine will be held in reset, preventing SPI transactions.

SPI pins support:

- internal pull-up resistors
- internal pull-down resistors
- open-drain or push-pull mode

## 24.5 Low-Power Mode

The SPI can be put into either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SPI. During global low-power mode, all clocks to the SPI are turned off, making the module completely inactive.

Local low-power mode is asserted by setting the POWERDOWN (SPIGCR1[8]) bit; setting this bit stops the clocks to the SPI internal logic and registers. Setting the POWERDOWN bit causes the SPI to enter local low-power mode and clearing the POWERDOWN bit causes SPI to exit from local low-power mode. All registers remain accessible during local power-down mode, since the clock to the SPI registers is temporarily re-enabled for each access. RAM buffers are also accessible during low power mode.

---

**NOTE:** Since entering a low-power mode has the effect of suspending all state-machine activities, care must be taken when entering such modes to ensure that a valid state is entered when low-power mode is active. Application software must ensure that a low power mode is not entered during a data transfer.

---

## 24.6 Interrupts

There are two levels of vectorized interrupts supported by the SPI. These interrupts can be caused under the following circumstances:

- Transmission error
- Receive overrun
- Receive complete (receive buffer full)
- Transmit buffer empty

These interrupts may be enabled or disabled via the SPIINT0 register.

During transmission, if one of the following errors occurs: BITERR, DESYNC, DLENERR, PARITYERR, or TIMEOUT, the corresponding bit in the SPIFLG register is set. If the corresponding enable bit is set, then an interrupt is generated. The level of all the above interrupts is set by the bit fields in the SPILVL register.

The error interrupts are enabled and prioritized independently from each other, but the interrupt generated will be the same if multiple errors are enabled on the same level. The SPIFLG register should be used to determine the actual cause of an error.

---

**NOTE:** Since there are two interrupt lines, one each for Level 0 and Level 1, it is possible for a programmer to separate out the interrupts for receive buffer full and transmit buffer empty. By programming one to Level 0 and the other to Level 1, it is possible to avoid a check on whether an interrupt occurred for transmit or for receive. A programmer can also choose to group all of the error interrupts into one interrupt line and both TX-empty and RX-full interrupts into another interrupt line using the LVL control register. In this way, it is possible to separate error-checking from normal data handling.

---

### 24.6.1 Interrupts in Multi-Buffer Mode

In multi-buffer mode, the SPI can generate interrupts on two levels.

In normal multi-buffer operation, the receive and transmit are not used and therefore the enable bits of SPIINT0 are not used.

The interrupts available in multi-buffer mode are:

- Transmission error interrupt
- Receive overrun interrupt
- TG suspended interrupt
- TG completed interrupt

When a TG has finished and the corresponding enable bit in the TGINTENA register is set, a transfer-finished interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

When a TG is suspended by a buffer that has been set as suspend to wait until TXFULL flag or/and RXEMPTY flag are set, and if the corresponding bit in the TGINTENA register is set, an transfer-suspended interrupt is generated. The level of priority of the interrupt is determined by the corresponding bit in the TGINTLVL register.

[Figure 24-23](#) illustrates the TG interrupts.

Figure 24-23. TG Interrupt Structure

During transmission, if one of the following errors occurs, BITERR, DESYNC, PARITYERR, TIMEOUT, DLENERR, the corresponding flag in the SPIFLG register is set. If the enable bit is set, then an interrupt is generated. The level of the interrupts could be generated according to the bit field in SPILVL register.

The RXOVRN interrupt is generated when a buffer in the RXRAM is overwritten by a new received word. While writing newly received data to a RXRAM location, if the RXEMPTY bit of the corresponding location is 0, then the RXOVR bit will be set to 1 during the write operation, so that the buffer starts to indicate an overrun. This RXOVR flag is also reflected in SPIFLG register as RXOVRNINTFLG and the corresponding vector number is updated in TGINTVECT0/TGINTVECT1 register. If an overrun interrupt is enabled, then an interrupt will be generated indicating an overrun condition.

The error interrupts are enabled and prioritized independently from each other, but the vector generated by the SPI will be the same if multiple errors are enabled on the same level.

Figure 24-24. SPIFLG Interrupt Structure

Since the priority of an error interrupt is lower than a completion/suspend interrupt for a TG, the interrupts can be split into two levels. By programming all the error interrupts into Level 0 and TG-complete / TG-suspend interrupts into Level 1, it is possible to get a clear indication of the source of error interrupts. However, when a vector register shows an error interrupt, the actual buffer for which the error has occurred is not readily identifiable. Since each buffer in the multi-buffer RAM is stored along with its individual status flags, each buffer should be read until a buffer with any error flag set is found.

A separate interrupt line is provided to indicate the uncorrectable error condition in the MibSPI. This line is available (and valid) only in the multi-buffer mode of the MibSPI module and if the parity error detection feature for multi-buffer RAM is enabled.

## 24.7 DMA Interface

In order to reduce CPU overhead in handling SPI message traffic on a character-by-character basis, SPI can use the DMA controller to transfer the data. The DMA request enable bit (DMA REQ EN) controls the assertion of requests to the DMA controller module. When a character is being transmitted or received, the SPI will signal the DMA via the DMA request signals, TX\_DMA\_REQ and RX\_DMA\_REQ. The DMA controller will then perform the required data transfer.

For efficient behavior during DMA operations, the transmitter empty and receive-buffer full interrupts can be disabled. For specific DMA features, see the DMA controller specification.

The SPI generates a request on the TX\_DMA\_REQ line each time the TX data is copied to the TX shift register either from the TXBUF or from peripheral data bus (when TXBUF is empty).

The first TX\_DMA\_REQ pulse is generated when either of the following is true:

- DMAREQEN (SPIINT0[16]) is set to 1 while SPIEN (SPIGCR1[24]) is already 1.
- SPIEN (SPIGCR1[24]) is set to 1 while DMAREQEN (SPIINT0[16]) is already 1.

The SPI generates a request on the RX\_DMA\_REQ line each time the received data is copied to the SPIBUF.

### 24.7.1 DMA in Multi-Buffer Mode

The MibSPI provides sophisticated programmable DMA control logic that completely eliminates the necessity of CPU intervention for data transfers, once programmed. When the multi-buffer mode is used, the DMA enable bit in the SPIINT0 register is ignored. DMA source or destination should be only the multi-buffer RAM and not SPIDAT0 / SPIDAT1 or SPIBUF register as in case of compatibility mode DMA.

The MibSPI offers up to eight DMA channels (for SEND and RECEIVE). All of the DMA channels are programmable individually and can be hooked to any buffer. The MibSPI provides up to 16 DMA request lines, and DMA requests from any channel can be programmed to be routed through any of these 16 lines. A DMA transfer can trigger both transmit and receive.

Each DMA channel has the capability to transfer a block of up to 32 data words without interruption using only one buffer of the array by configuring the DMAxCTRL register. Using the DMAxCOUNT and DMACTNTLEN register, up to 65535 (64K) words of data can be transferred without any interruption using just one buffer of the array. This enables the transfer of memory blocks from or into an external SPI memory.

Figure 24-25. DMA Channel and Request Line (Logical) Structure in Multi-buffer Mode

## 24.8 Module Configuration

MibSPI/MibSPIP can be configured to function as Normal SPI and Multi-buffered SPI. Upon power-up or a system-level reset, each bit in the module registers is set to a default state. The registers are writable only after the RESET bit is set to 1.

### 24.8.1 Compatibility (SPI) Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Configure the SIMO, SOMI, SPICLK, and optional  $\overline{\text{SPICS}}$  and  $\overline{\text{SPIENA}}$  pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Enable the Interrupts using SPIINT0 register if required.
- Select the chip select to be used by setting CSNR bits in SPIDAT1 register.
- Configure CSHOLD and WDEL bits in SPIDAT1 register if required.
- Select the Data word format by setting DFSEL bits. Select the Number of the configured SPIFMTx register (0 to 3) to used for the communication.
- Set LOOPBACK bit to connect the transmitter to the receiver internally. (This feature is used to perform a self-test. Do not configure for normal communication to external devices).
- Set SPIEN bit to 1 after the SPI is configured.
- Perform Transmit and receive data, using SPIDAT1 and SPIBUF register.
- You must wait for TXFULL to reset or TXINT before writing next data to SPIDAT1 register.
- You must wait for RXEMPTY to reset or RXINT before reading the data from SPIBUF register.

### 24.8.2 MibSPI Mode Configuration

The following list details the configuration steps that software should perform prior to the transmission or reception of data in MIBSPI mode. As long as the SPIEN bit in the Global Control Register 1 (SPIGCR1) is cleared to 0 the entire time that the SPI is being configured, the order in which the registers are programmed is not important.

- Enable SPI by setting RESET bit.
- Set MSPIENA bit to 1 to get access to multi-buffer mode registers.
- Configure the SIMO, SOMI, SPICLK, and optional  $\overline{\text{SPICS}}$  and  $\overline{\text{SPIENA}}$  pins for SPI functionality by setting the corresponding bit in SPIPC0 register.
- Configure the module to function as Master or Slave using CLKMOD and MASTER bits.
- Configure the required SPI data format using SPIFMTx register.
- If the module is selected to function as Master, the delay parameters can be configured using SPIDELAY register.
- Check for BUFINITACTIVE bit to be active before configuring MIBSPI RAM. (From Device Power On it take Number of Buffers  $\times$  Peripheral clock period to initialize complete RAM.)
- Enable the Transfer Group interrupts using TGITENST register if required.
- Enable error interrupts using SPIINT0 register if required.
- Set SPIEN bit to 1 after the SPI is configured.
- The Trigger Source, Trigger Event, Transfer Group start address for the corresponding Transfer groups can be configured using the corresponding TGxCTRL register.
- Configure LPEND to specify the end address of the last TG.
- Similar to SPIDAT1 register, the 16 bit control fields in every TXRAM buffer in the TG have to be configured.
- Configure one of the eight BUFMODE available for each buffer.
- Fill the data to be transmitted in TXDATA field in TXRAM buffers.
- Configure TGENA bit to enable the required Transfer groups. (In case of Trigger event always setting TGENA will trigger the transfer group).
- At the occurrence of the correct trigger event, the Transfer group will be triggered and data gets transmitted and received one after the other with out any CPU intervention.
- You can poll Transfer group interrupt flag or wait for a transfer-completed interrupt to read and write new data to the buffers.

## 24.9 Control Registers

This section describes the SPI control, data, and pin registers. The registers support 8-bit, 16-bit and 32-bit writes. The offset is relative to the associated base address of this module in a system. The base address for the control registers is FFF7 F400h for MibSPI1, FFF7 F600h for SPI2, FFF7 F800h for MibSPI3, FFF7 FA00h for SPI4, and FFF7 FC00h for MibSPI5.

**NOTE:** TI highly recommends that write values corresponding to the reserved locations of registers be maintained as 0 consistently. This allows future enhancements to use these reserved bits as control bits without affecting the functionality of the module with any older versions of software.

**Table 24-7. SPI Registers**

| Offset  | Acronym               | Register Description                          | Section                         |
|---------|-----------------------|-----------------------------------------------|---------------------------------|

| 16    | LOOPBACK  | 0<br>1 | <p>Internal loop-back test mode. The internal self-test option can be enabled by setting this bit. If the SPISIMO and SPISOMI pins are configured with SPI functionality, then the SPISIMO[7:0] pins are internally connected to the SPISOMI[7:0] pins (transmit data is looped back as receive data). GIO mode for these pins is not supported in loopback mode. Externally, during loop-back operation, the SPICLK pin outputs an inactive value and SPISOMI[7:0] remains in the high-impedance state. If the SPI is initialized in slave mode or a data transfer is ongoing, errors may result.</p> <p><b>Note: This loopback mode can only be used in master mode. Master mode must be selected before setting LOOPBACK. When this mode is selected, the CLKMOD bit should be set to 1, meaning that SPICLK is internally generated.</b></p> <p>Internal loop-back test mode is disabled.</p> <p>Internal loop-back test mode is enabled.</p> |

**Table 24-10. SPI Interrupt Register (SPIINT0) Field Descriptions**

| Bit   | Field       | Value | Description                                                                                                                                                                                                                                                                                                                        |
|-------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved    | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                             |
| 24    | ENABLEHIGHZ |       | $\overline{\text{SPIEN}}_{\text{A}}$ pin high-impedance enable. When active, the $\overline{\text{SPIEN}}_{\text{A}}$ pin (when it is configured as a WAIT functional output signal in a slave SPI) is forced to high-impedance when not driving a low signal. If inactive, then the pin will output both a high and a low signal. |
|       |             | 0     | $\overline{\text{SPIEN}}_{\text{A}}$ pin is pulled high when not active.                                                                                                                                                                                                                                                           |
|       |             | 1     | $\overline{\text{SPIEN}}_{\text{A}}$ pin remains high-impedance when not active.                                                                                                                                                                                                                                                   |
| 23-17 | Reserved    | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                             |
| 16    | DMAREQEN    |       | DMA request enable. Enables the DMA request signal to be generated for both receive and transmit channels. Enable DMA REQ only after setting the SPIEN bit to 1.                                                                                                                                                                   |
|       |             | 0     | DMA is not used.                                                                                                                                                                                                                                                                                                                   |
|       |             | 1     | DMA requests will be generated.                                                                                                                                                                                                                                                                                                    |
|       |             |       | <b>Note: A DMA request will be generated on the TX DMA REQ line each time a word is copied to the shift register either from TXBUF or directly from SPIDAT0/SPIDAT1 writes.</b>                                                                                                                                                    |
|       |             |       | <b>Note: A DMA request will be generated on the RX DMA REQ line each time a word is copied to the SPIBUF register either from RXBUF or directly from the shift register.</b>                                                                                                                                                       |
| 15-10 | Reserved    | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                             |

**Table 24-10. SPI Interrupt Register (SPIINT0) Field Descriptions (continued)**

| Bit | Field        | Value                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 24    | BUFINITACTIVE | 0<br>1 | Indicates the status of multi-buffer initialization process. Software can poll for this bit to determine if it can proceed with the register configuration of multi-buffer mode registers or buffer handling.<br><br><b>Note: If the SPIFLG register is read while the multi-buffer RAM is being initialized, the BUFINITACTIVE bit will be read as 1. If SPIFLG is read after the internal automatic buffer initialization is complete, this bit will be read as 0. This bit will show a value of 1 as long as the nRESET bit is 0, but does not really indicate that buffer initialization is underway. Buffer initialization starts only when the nRESET bit is set to 1.</b><br><br>0 Multi-buffer RAM initialization is complete.<br>1 Multi-buffer RAM is still being initialized. Do not attempt to write to either multi-buffer RAM or any multi-buffer mode registers. |
| 23-10 | Reserved      | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9     | TXINTFLG      | 0<br>1 | Transmitter-empty interrupt flag. Serves as an interrupt flag indicating that the transmit buffer (TXBUF) is empty and a new word can be written to it. This flag is set when a word is copied to the shift register either directly from SPIDAT0/SPIDAT1 or from the TXBUF register. This bit is cleared by one of following methods:<br><ul style="list-style-type: none"> <li>Writing a new data to either SPIDAT0 or SPIDAT1</li> <li>Writing a 0 to SPIEN (SPIGCR1[24])</li> </ul> 0 Transmit buffer is now full. No interrupt pending for transmitter empty.<br>1 Transmit buffer is empty. An interrupt is pending to fill the transmitter.                                                                                                                                                                                                                              |

**Table 24-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)**

| Bit | Field        | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----|--------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | RXINTFLG     | <div>0</div> <div>1</div> | <p>Receiver-full interrupt flag. This flag is set when a word is received and copied into the buffer register (SPIBUF). If RXINTEN is enabled, an interrupt is also generated. This bit is cleared under the following methods:</p> <ul style="list-style-type: none"><li>• Reading the SPIBUF register</li><li>• Reading TGINTVECT0 or TGINTVECT1 register when there is a receive buffer full interrupt</li><li>• Writing a 1 to this bit</li><li>• Writing a 0 to SPIEN (SPIGCR1[24])</li><li>• System reset</li></ul> <p>During emulation mode, however, a read to the emulation register (SPIEMU) does not clear this flag bit.</p> <p><b>Note: Clearing RXINTFLG bit by writing a 1 before reading the SPIBUF sets the RXEMPTY bit of the SPIBUF register too. In this way, one can ignore a received word. However, if the internal RXBUF is already full, the data from RXBUF will be copied to SPIBUF and the RXEMPTY bit will be cleared again. The SPIBUF contents should be read first if this situation needs to be avoided.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 6   | RXOVRNINTFLG | <div>0</div> <div>1</div> | <p>Receiver overrun flag. The SPI hardware sets this bit when a receive operation completes before the previous character has been read from the receive buffer. The bit indicates that the last received character has been overwritten and therefore lost. The SPI will generate an interrupt request if this bit is set and the RXOVRN INTEN bit (SPIINT0.6) is set high. This bit is cleared under the following conditions in compatibility mode of MibSPI:</p> <ul style="list-style-type: none"><li>• Reading TGINTVECT0 or TGINTVECT1 register when there is a receive-buffer-overrun interrupt</li><li>• Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself</li><li>• Writing a 0 to SPIEN</li><li>• Reading the data field of the SPIBUF register</li></ul> <p><b>Note: Reading the SPIBUF register does not clear this RXOVRNINTFLG bit. If an RXOVRN interrupt is detected, then the SPIBUF may need to be read twice to get to the overrun buffer. This is due to the fact that the overrun will always occur to the internal RXBUF. Each read to the SPIBUF will result in RXBUF contents (if it is full) getting copied to SPIBUF.</b></p> <p><b>Note: There is a special condition under which the RXOVRNINTFLG flag gets set. If both SPIBUF and RXBUF are already full and while another reception is underway, if any errors (TIMEOUT, BITERR, and DLEN_ERR) occur, then RXOVRN in RXBUF and RXOVRNINTFLG in SPIFLG registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a receive overrun.</b></p> <p>In multi-buffer mode of MibSPI, this bit is cleared under the following conditions:</p> <ul style="list-style-type: none"><li>• Reading the RXOVRN_BUF_ADDR register</li><li>• Writing a 1 to RXOVRNINTFLG in the SPI Flag Register (SPIFLG) itself</li></ul> <p>In multi-buffer mode, if RXOVRNINTFLG is set, then the address of the buffer which experienced the overrun is available in RXOVRN_BUF_ADDR.</p> |

This flag can be cleared by one of the following methods.</p> <ul style="list-style-type: none"><li>• Write a 1 to this bit</li><li>• Clear the SPIEN bit to 0</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 24-12. SPI Flag Register (SPIFLG) Field Descriptions (continued)**

| Bit | Field      | Value                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | DESYNCFLG  | <div><div>0</div><div>1</div></div> | <div>Desynchronization of slave device. Desynchronization monitor is active in master mode only. This flag can be cleared by one of the following methods:<ul style="list-style-type: none"><li>• Write a 1 to this bit</li><li>• Clear the SPIEN bit to 0</li></ul></div> <div>No slave desynchronization is detected.</div> <div>A slave device is desynchronized. The master monitors the ENable signal coming from the slave device and sets the DESYNC flag after the last bit is transmitted plus <math>t_{T2EDELAY}</math>. If DESYNCENA is set an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</div>                                                                                                                                          |
| 2   | PARERRFLG  | <div><div>0</div><div>1</div></div> | <div>Calculated parity differs from received parity bit. If the parity generator is enabled (can be selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word the parity generator calculates the reference parity and compares it to the received parity bit. In the event of a mismatch the PARITYERR flag is set and an interrupt is asserted if PARERRENA is set. This flag can be cleared by one of the following methods:<ul style="list-style-type: none"><li>• Write a 1 to this bit</li><li>• Clear the SPIEN bit to 0</li></ul></div> <div>No parity error is detected.</div> <div>A parity error occurred.</div>                                                                                                                  |
| 1   | TIMEOUTFLG | <div><div>0</div><div>1</div></div> | <div>Time-out caused by nonactivation of ENA signal. This flag can be cleared by one of the following methods:<ul style="list-style-type: none"><li>• Write a 1 to this bit</li><li>• Clear the SPIEN bit to 0</li></ul></div> <div>No ENA-signal time-out occurred.</div> <div>An ENA signal time-out occurred. The SPI generates a time-out because the slave hasn't responded in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition the TIMEOUT flag in the status field of the corresponding buffer is set. The transmit request of the concerned buffer is cleared, that is, the SPI does not re-start a data transfer from this buffer.</div> |
| 0   | DLENERRFLG | <div><div>0</div><div>1</div></div> | <div>Data-length error flag. This flag can be cleared by one of the following methods:<ul style="list-style-type: none"><li>• Write a 1 to this bit</li><li>• Clear the SPIEN bit to 0</li></ul></div> <div><b>Note: Whenever any transmission errors (TIMEOUT, BITERR, DLEN_ERR, PARITY_ERR, DESYNC) are detected and the error flags are cleared by writing to the error bit in the SPIFLG register, the corresponding error flag in SPIBUF does not get cleared. Software needs to read the SPIBUF until it becomes empty before proceeding. This ensures that all of the old status bits in SPIBUF are cleared before starting the next transfer.</b></div> <div>No data length error has occurred.</div> <div>A data length error has occurred.</div>                                                                |

## 24.9.6 SPI Pin Control Register 0 (SPIPC0)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

### 24.9.7 SPI Pin Control Register 1 (SPIPC1)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

If the SPISOMI[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.                                                                                            |
|       |          | 0     | The SPISOMI[0] pin is an input.                                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | The SPISOMI[0] pin is an output.                                                                                                                                                                                                                                                                                                                       |
| 10    | SIMODIR0 |       | SPISIMO[0] direction. This bit controls the direction of the SPISIMO[0] pin when it is used as a general-purpose I/O pin. If the SPISIMO[0] pin is used as a SPI functional pin, the I/O direction is determined by the MASTER bit in the SPIGCR1 register.                                                                                            |
|       |          | 0     | The SPISIMO[0] pin is an input.                                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | The SPISIMO[0] pin is an output.                                                                                                                                                                                                                                                                                                                       |
| 9     | CLKDIR   |       | SPICLK direction. This bit controls the direction of the SPICLK pin when it is used as a general-purpose I/O pin. In functional mode, the I/O direction is determined by the CLKMOD bit.                                                                                                                                                               |
|       |          | 0     | The SPICLK pin is an input.                                                                                                                                                                                                                                                                                                                            |
|       |          | 1     | The SPICLK pin is an output.                                                                                                                                                                                                                                                                                                                           |
| 8     | ENADIR   |       | $\overline{\text{SPIENA}}$ direction. This bit controls the direction of the $\overline{\text{SPIENA}}$ pin when it is used as a general-purpose I/O. If the $\overline{\text{SPIENA}}$ pin is used as a functional pin, then the I/O direction is determined by the CLKMOD bit (SPIGCR1[1]).                                                          |
|       |          | 0     | The $\overline{\text{SPIENA}}$ pin is an input.                                                                                                                                                                                                                                                                                                        |
|       |          | 1     | The $\overline{\text{SPIENA}}$ pin is an output.                                                                                                                                                                                                                                                                                                       |
| 7-0   | SCSDIR   |       | $\overline{\text{SPICS}}$ direction. These bits control the direction of each $\overline{\text{SPICS}}$ pin when it is used as a general-purpose I/O pin. Each pin could be configured independently from the others if the $\overline{\text{SPICS}}$ is used as a SPI functional pin. The I/O direction is determined by the CLKMOD bit (SPIGCR1[1]). |
|       |          | 0     | The $\overline{\text{SPICS}}$ pin is an input.                                                                                                                                                                                                                                                                                                         |
|       |          | 1     | The $\overline{\text{SPICS}}$ pin is an output.                                                                                                                                                                                                                                                                                                        |

## 24.9.8 SPI Pin Control Register 2 (SPIPC2)

**NOTE: Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

## 24.9.9 SPI Pin Control Register 3 (SPIPC3)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

### 24.9.10 SPI Pin Control Register 4 (SPIPC4)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

|       |          | 1     | Read: $\overline{\text{SPICS}}$ is logic 1.<br>Write: Logic 1 is placed on $\overline{\text{SPICS}}$ pin, if it is in general-purpose output mode.                                                                                                                                                                              |

## 24.9.11 SPI Pin Control Register 5 (SPIPC5)

**NOTE: Register bits vary by device**

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

**Figure 24-36. SPI Pin Control Register 5 (SPIPC5) [offset = 28h]**

LEGEND: R/W = Read/Write; R = Read only; U = Undefined; -n = value after reset

**Table 24-18. SPI Pin Control Register 5 (SPIPC5) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                           |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | SOMICLR  |       | SPISOMI[x] data out clear. This pin is only active when the SPISOMI[x] pin is configured as a general-purpose output pin.                                                                                                             |
|       |          | 0     | <b>Bit 11 or bit 24 can be used to set the SPISOMI[0] pin. If a 32-bit write is performed, bit 11 will have priority over bit 24.</b><br>Read: The current value on SPISOMI[x] is 0.<br>Write: Writing a 0 to this bit has no effect. |
|       |          | 1     | Read: The current value on SPISOMI[x] is 1.<br>Write: Logic 0 is placed on SPISOMI[x] pin, if it is in general-purpose output mode.                                                                                                   |
| 23-16 | SIMOCLR  |       | SPISIMO[x] data out clear. This bit is only active when the SPISIMO[x] pin is configured as a general-purpose output pin.                                                                                                             |
|       |          | 0     | <b>Bit 10 or bit 16 can be used to set the SPISIMO[0] pin. If a 32-bit write is performed, bit 10 will have priority over bit 16.</b><br>Read: The current value on SPISIMO[x] is 0.<br>Write: Writing a 0 to this bit has no effect. |
|       |          | 1     | Read: The current value on SPISIMO[x] is 1.<br>Write: Logic 0 is placed on SPISIMO[x] pin, if it is in general-purpose output mode.                                                                                                   |
| 15-12 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                |
| 11    | SOMICLR0 |       | SPISOMI[0] data out clear. This pin is only active when the SPISOMI[0] pin is configured as a general-purpose output pin.                                                                                                             |

### 24.9.12 SPI Pin Control Register 6 (SPIPC6)

**NOTE:** Register bits vary by device

Register bits 31:24 and 23:16 of SPIPC0 to SPIPC9 reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

## 24.9.13 SPI Pin Control Register 7 (SPIPC7)

### NOTE: Register bits vary by device

Register bits 31:24 and 23:16 of this register reflect the number of SIMO/SOMI data lines per device. On devices with 8 data-line support, all of bits 31 to 16 are implemented. On devices with less than 8 data lines, only a subset of these bits are available. Unimplemented bits return 0 upon read and are not writable.

### NOTE: Default Register Value

The default values of these register bits vary by device. See your device datasheet for information about default pin states, which correspond to the register reset values (see the pin-list table).

| 15-0  | TXDATA   | 0-FFFFh | <p>SPI transmit data. When written, these bits will be copied to the shift register if it is empty. If the shift register is not empty, TXBUF holds the written data. SPIEN (SPICGR1[24]) must be set to 1 before this register can be written to. Writing a 0 to the SPIEN register forces the lower 16 bits of the SPIDAT0 to 0x00.</p> <p><b>Note:</b> When this register is read, the contents TXBUF, which holds the latest written data, will be returned.</p> <p><b>Note:</b> Regardless of character length, the transmit word should be right-justified before writing to the SPIDAT1 register.</p> <p><b>Note:</b> The default data format control register for SPIDAT0 is SPIFMT0. However, it is possible to reprogram the DFSEL[1:0] fields of SPIDAT1 before using SPIDAT0, to select a different SPIFMTx register.</p> <p><b>Note:</b> It is highly recommended to use SPIDAT1 register, SPIDAT0 is supported for compatibility reasons.</p> |

## 24.9.16 SPI Transmit Data Register 1 (SPIDAT1)

**NOTE:** Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 28    | CSHOLD   | 0     | Chip select hold mode. The CSHOLD bit is supported in master mode only in compatibility-mode of SPI, (it is ignored in slave mode). CSHOLD defines the behavior of the chip select line at the end of a data transfer.<br>The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.                                        |
|       |          | 1     | The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.                                                                                                                                                                                                |
| 27    | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 26    | WDEL     | 0     | Enable the delay counter at the end of the current transaction.<br><b>Note: The WDEL bit is supported in master mode only. In slave mode, this bit will be ignored.</b><br>No delay will be inserted. However, the <b>SPICS</b> pins will still be de-activated for at least for 2VCLK cycles if CSHOLD = 0.                                                                                                                                                                                                                               |
|       |          | 1     | <b>Note: The duration for which the SPICS pin remains deactivated depends upon the time taken to supply a new word after completing the shift operation. If TXBUF is already full, then the SPICS pin will be deasserted for at least two VCLK cycles (if WDEL = 0).</b><br>After a transaction, WDELAY of the corresponding data format will be loaded into the delay counter. No transaction will be performed until the WDELAY counter overflows. The SPICS pins will be de-activated for at least (WDELAY + 2) × VCLK_Period duration. |

| 23-16 | CSNR     | 0-FFh | Chip select (CS) number. CSNR defines the chip select pins that will be activated during the data transfer. CSNR is a bit-mask that controls all chip select pins. See <a href="#">Table 24-24</a> .<br><b>Note: If your MibSPI has less than 8 chip select pins, all unused upper bits will be 0. For example, MiBSP13 has 6 chip select pins, if you write FFh to CSNR, the actual number stored in CSNR is 3Fh.</b>                                                                                                                     |

**Table 24-23. SPI Transmit Data Register 1 (SPIDAT1) Field Descriptions (continued)**

| Bit  | Field  | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|--------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | TXDATA | 0-FFFFh | <p>Transfer data. When written, these bits are copied to the shift register if it is empty. If the shift register is not empty, then they are held in TXBUF.</p> <p>SPIEN must be set to 1 before this register can be written to. Writing a 0 to SPIEN forces the lower 16 bits of SPIDAT1 to 0x0000.</p> <p>A write to this register (or to the TXDATA field only) drives the contents of the CSNR field on the <math>\overline{\text{SPICS}}</math> pins, if the pins are configured as functional pins (automatic chip select, see <a href="#">Section 24.2</a>).</p> <p>When this register is read, the contents of TXBUF, which holds the latest data written, will be returned.</p> <p><b>Note:</b> Regardless of the character length, the transmit data should be right-justified before writing to the SPIDAT1 register.</p> |

| 31  | RXEMPTY | 0<br>1 | <p>Receive data buffer empty. When the host reads the RXDATA field or the entire SPIBUF register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into RXDATA.</p> <p>No data has been received since the last read of RXDATA.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> <li>Reading the RXDATA field of the SPIBUF register</li> <li>Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG)</li> </ul> <p>Write-clearing the RXINTFLG bit before reading the SPIBUF indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of SPIBUF (or the entire register).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30  | RXOVR   | 0<br>1 | <p>Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to SPIBUF; the contents of SPIBUF are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVCTx shows the RXOVRN condition. Two read operations from the SPIBUF register are required to reach the overwritten buffer word (one to read SPIBUF, which then transfers RXDATA into SPIBUF for the second read).</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p><b>Note: A special condition under which RXOVR flag gets set. If both SPIBUF and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</b></p> <p>No receive data overrun condition occurred since last read of the data field.</p> <p>A receive data overrun condition occurred since last read of the data field.</p> |
| 29  | TXFULL  | 0<br>1 | <p>Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.</p> <p>The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.</p> <p>The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 24-25. SPI Receive Buffer Register (SPIBUF) Field Descriptions (continued)**

| Bit   | Field     | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28    | BITERR    | 0<br>1  | <p>Bit error. There was a mismatch of internal transmit data and transmitted data.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p>No bit error occurred.</p> <p>A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 27    | DESYNC    | 0<br>1  | <p>Desynchronization of slave device. This bit is valid in master mode only.</p> <p>The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus <math>t_{2EDELAY}</math>. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</p> <p><b>Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always assured to be for the current buffer.</b></p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p>No slave desynchronization is detected.</p> <p>A slave device is desynchronized.</p> |
| 26    | PARITYERR | 0<br>1  | <p>Parity error. The calculated parity differs from the received parity bit.</p> <p>If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p>No parity error is detected.</p> <p>A parity error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25    | TIMEOUT   | 0<br>1  | <p>Time-out because of non-activation of <math>\overline{\text{SPIEN}}_A</math> pin.</p> <p>The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.</p> <p><b>Note: This bit is valid only in master mode.</b></p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p>No <math>\overline{\text{SPIEN}}_A</math> pin time-out occurred.</p> <p>An <math>\overline{\text{SPIEN}}_A</math> signal time-out occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 24    | DLENERR   | 0<br>1  | <p>Data length error flag.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the SPIBUF register is read.</b></p> <p>No data-length error occurred.</p> <p>A data length error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23-16 | LCSNR     | 0-FFh   | <p>Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. | Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | C2TDELAY | 0-FFh | <p>Chip-select-active to transmit-start delay. See <a href="#">Figure 24-45</a> for an example. C2TDELAY is used only in master mode. It defines a setup time (for the slave device) that delays the data transmission from the chip select active edge by a multiple of VCLK cycles.</p> <p>The setup time value is calculated as follows.</p> $t_{C2TDELAY} = (C2TDELAY + 2) \times VCLK \text{ Period}$ <p>Example: VCLK = 25 MHz -&gt; VCLK Period = 40ns; C2TDELAY = 07h;<br/> <math>t_{C2TDELAY} = 360 \text{ ns}</math></p> <p>When the chip select signal becomes active, the slave has to prepare data transfer within 360 ns.</p> <p><b>Note:</b> If phase = 1, the delay between SPICS falling edge to the first edge of SPICLK will have an additional 0.5 SPICLK period delay. This delay is as per the SPI protocol.</p> |

**Table 24-27. SPI Delay Register (SPIDELAY) Field Descriptions (continued)**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23-16 | T2CDELAY | 0-FFh | <p>Transmit-end-to-chip-select-inactive-delay. See <a href="#">Figure 24-46</a> for an example. T2CDELAY is used only in master mode. It defines a hold time for the slave device that delays the chip select deactivation by a multiple of VCLK cycles after the last bit is transferred.</p> <p>The hold time value is calculated as follows:<br/> <math>t_{T2CDELAY} = (T2CDELAY + 1) \times VCLK \text{ Period}</math><br/> Example: VCLK = 25 MHz → VCLK Period = 40ns; T2CDELAY = 03h;<br/> <math>&gt; t_{T2CDELAY} = 160 \text{ ns}</math></p> <p>After the last data bit (or parity bit) is being transferred the chip select signal is held active for 160 ns.</p> <p><b>Note: If phase = 0, then between the last edge of SPICLK and rise-edge of SPICS there will be an additional delay of 0.5 SPICLK period. This is as per the SPI protocol.</b></p> <p>Both C2DELAY and T2CDELAY counters do not have any dependency on the <math>\overline{SPIENA}</math> pin value. Even if the <math>\overline{SPIENA}</math> pin is asserted by the slave, the master will continue to delay the start of SPICLK until the C2DELAY counter overflows.</p> <p>Similarly, even if the <math>\overline{SPIENA}</math> pin is deasserted by the slave, the master will continue to hold the SPICS pins active until the T2CDELAY counter overflows. In this way, it is assured that the setup and hold times of the SPICS pins are determined by the delay timers alone. To achieve better throughput, it should be ensured that these two timers are kept at the minimum possible values.</p> |
| 15-8  | T2EDELAY | 0-FFh | <p>Transmit-data-finished to ENA-pin-inactive time-out. T2EDELAY is used in master mode only. It defines a time-out value as a multiple of SPI clock before <math>\overline{SPIENA}</math> signal has to become inactive and after SPICS becomes inactive. SPICLK depends on which data format is selected. If the slave device is missing one or more clock edges, it becomes de-synchronized. In this case, although the master has finished the data transfer, the slave is still waiting for the missed clock pulses and the ENA signal is not disabled.</p> <p>The T2EDELAY defines a time-out value that triggers the DESYNC flag, if the <math>\overline{SPIENA}</math> signal is not deactivated in time. The DESYNC flag is set to indicate that the slave device did not de-assert its <math>\overline{SPIENA}</math> pin in time to acknowledge that it received all bits of the sent word. See <a href="#">Figure 24-47</a> for an example of this condition.</p> <p><b>Note: DESYNC is also set if the SPI detects a de-assertion of <math>\overline{SPIENA}</math> before the end of the transmission.</b></p> <p>The time-out value is calculated as follows:<br/> <math>t_{T2EDELAY} = T2EDELAY / SPIclock</math><br/> Example: SPIclock = 8 Mbit/s; T2EDELAY = 10h;<br/> <math>&gt; t_{T2EDELAY} = 2 \mu s</math></p> <p>The slave device has to disable the ENA signal within 2 <math>\mu s</math>, otherwise DESYNC is set and an interrupt is asserted (if enabled).</p>                                                                                                  |
| 7-0   | C2EDELAY | 0-FFh | <p>Chip-select-active to ENA-signal-active time-out. C2EDELAY is used only in master mode and it applies only if the addressed slave generates an ENA signal as a hardware handshake response. C2EDELAY defines the maximum time between when the SPI activates the chip-select signal and the addressed slave has to respond by activating the ENA signal. C2EDELAY defines a time-out value as a multiple of SPI clocks. The SPI clock depends on whether data format 0 or data format 1 is selected. See <a href="#">Figure 24-48</a> for an example of this condition.</p> <p><b>Note: If the slave device does not respond with the ENA signal before the time-out value is reached, the TIMEOUT flag in the SPIFLG register is set and a interrupt is asserted (if enabled).</b></p> <p>If a time-out occurs, the SPI clears the transmit request of the timed-out buffer, sets the TIMEOUT flag for the current buffer, and continues with the transfer of the next buffer in the sequence that is enabled.</p> <p>The timeout value is calculated as follows:<br/> <math>t_{C2EDELAY} = C2EDELAY / SPIclock</math><br/> Example: SPIclock = 8 Mbit/s; C2EDELAY = 30h;<br/> <math>&gt; t_{C2EDELAY} = 6 \text{ ms}</math></p> <p>The slave device has to activate the ENA signal within 6 ms after the SPI has activated the chip select signal (SPICS), otherwise the TIMEOUT flag is set and an interrupt is asserted (if enabled).</p>                                                                                                                                              |

| Bit   | Field     | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | WDELAY    | 0-FFh  | Delay in between transmissions for data format x (x= 0,1,2,3). Idle time that will be applied at the end of the current transmission if the bit WDEL is set in the current buffer. The delay to be applied is equal to:<br>$WDELAY \times P_{VCLK} + 2 \times P_{VCLK}$<br>$P_{VCLK} \rightarrow$ Period of VCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 23    | PARPOL    | 0<br>1 | Parity polarity: even or odd. PARPOLx can be modified in privilege mode only. It can be used for data format x (x= 0,1,2,3).<br>0<br>An even parity flag is added at the end of the transmit data stream.<br>1<br>An odd parity flag is added at the end of the transmit data stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 22    | PARITYENA | 0<br>1 | Parity enable for data format x.<br>No parity generation/ verification is performed for this data format.<br>0<br>A parity bit is transmitted at the end of each transmitted word. At the end of a transfer the parity generator compares the received parity bit with the locally-calculated parity flag. If the parity bits do not match, the RXERR flag is set in the corresponding control field. The parity type (even or odd) can be selected via the PARPOL bit.<br>1<br><b>Note: If an uncorrectable error flag is set in a slave-mode SPI, then the wrong parity bit will be transmitted to indicate to the master that there has been some issue with the data parity. The SPISOMI pins will be forced to transmit all 0s, and the parity bit will be transmitted as 1 if even parity is selected and as 0 if odd parity is selected (using the PARPOLx bit of this register). This behavior occurs regardless of an uncorrectable parity error on either TXRAM or RXRAM.</b> |
| 21    | WAITENA   | 0<br>1 | The master waits for the ENA signal from slave for data format x. WAITENA is valid in master mode only. WAITENA enables a flexible SPI network where slaves with ENA signal and slaves without ENA signal can be mixed. WAITENA defines, for each transferred word, whether the addressed slave generates the ENA signal or not.<br>0<br>The SPI does not wait for the ENA signal from the slave and directly starts the transfer.<br>1<br>Before the SPI starts the data transfer it waits for the ENA signal to become low. If the ENA signal is not pulled down by the addressed slave before the internal time-out counter (C2EDELAY) overflows, then the master aborts the transfer and sets the TIMEOUT error flag.                                                                                                                                                                                                                                                               |
| 20    | SHIFTDIR  | 0<br>1 | Shift direction for data format x. With bit SHIFTDIRx, the shift direction for data format x (x=0,1,2,3) can be selected.<br>0<br>MSB is shifted out first.<br>1<br>LSB is shifted out first.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 24-29. SPI Data Format Registers (SPIFMT) Field Descriptions (continued)**

| Bit  | Field         | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|---------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19   | HDUPLEX_ENAx  | 0<br>1 | <p>Half Duplex transfer mode enable for Data Format x. This bit controls the I/O function of SOMI/SIMO lines for a specific requirement where in the case of Master mode, TX pin - SIMO will act as an RX pin, and in the case of Slave mode, RX pin - SIMO will act as a TX pin.</p> <p>Normal Full Duplex transfer.</p> <p>If MASTER = 1, SPISIMO pin will act as an RX pin (No TX possible) If MASTER = 0, SPISIMO pin will act as a TX pin (No RX possible).</p> <p>For all normal operations, HDUPLEX_ENAx bits should always remain 0. It is intended for the usage when the SPISIMO pin is used for both TX and RX operations at different times.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 18   | DIS CS TIMERS | 0<br>1 | <p>Disable chip-select timers for this format. The C2TDELAY and T2CDELAY timers are by default enabled for all the data format registers. Using this bit, these timers can be disabled for a particular data format, if they are not required. When a master is handling multiple slaves, with varied set-up hold requirement, the application can selectively choose to include or not include the chip-select delay timers for any slaves.</p> <p>Both C2TDELAY and T2CDELAY counts are inserted for the chip selects.</p> <p>No C2TDELAY or T2CDELAY is inserted in the chip select timings.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 17   | POLARITY      | 0<br>1 | <p>SPI data format x clock polarity. POLARITYx defines the clock polarity of data format x. The following restrictions apply when switching clock phase and/or polarity:</p> <ul style="list-style-type: none"> <li>In 3-pin/4-pin with <math>\overline{\text{SPIEN}}_A</math> pin configuration of a slave SPI, the clock phase and polarity cannot be changed on-the-fly between two transfers. The slave should be reset and reconfigured if clock phase/polarity needs to be switched. In summary, SPI format switching is not fully supported in slave mode.</li> <li>Even while using chip select pins, the polarity of SPICLK can be switched only while the slave is not selected by a valid chip select. The master SPI should ensure that while switching SPICLK polarity, it has deselected all of its slaves. Otherwise, the switching of SPICLK polarity may be incorrectly treated as a clock edge by some slaves.</li> </ul> <p>If POLARITYx is cleared to 0, the SPI clock signal is low-inactive, that is, before and after data transfer the clock signal is low.</p> <p>If POLARITYx is set to 1, the SPI clock signal is high-inactive, that is, before and after data transfer the clock signal is high.</p> |
| 16   | PHASE         | 0<br>1 | <p>SPI data format x clock delay. PHASEx defines the clock delay of data format x.</p> <p>If PHASEx is cleared to 0, the SPI clock signal is not delayed versus the transmit/receive data stream. The first data bit is transmitted with the first clock edge and the first bit is received with the second (inverse) clock edge.</p> <p>If PHASEx is set to 1, the SPI clock signal is delayed by a half SPI clock cycle versus the transmit/receive data stream. The first transmit bit has to output prior to the first clock edge. The master and slave receive the first bit with the first edge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 15-8 | PRESCALE      |        | <p>SPI data format x prescaler. PRESCALEx determines the bit transfer rate of data format x if the SPI is the network master. PRESCALEx is use to derive SPICLK from VCLK. If the SPI is configured as slave, PRESCALEx <b>does not need</b> to be configured. The clock rate for data format x can be calculated as:</p> $\text{BR}_{\text{Formatx}} = \text{VCLK} / (\text{PRESCALEx} + 1)$ <p><b>Note: When PRESCALEx is cleared to 0, the SPI clock rate defaults to VCLK/2.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 7-5  | Reserved      | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 4-0  | CHARLEN       | 0-1Fh  | SPI data format x data-word length. CHARLENx defines the word length of data format x. Legal values are 0x02 (data word length = 2 bit) to 10h (data word length = 16). Illegal values, such as 00 or 1Fh are not allowed; their effect is indeterminate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 24.9.22 Interrupt Vector 0 (INTVECT0)

**NOTE:** The TG interrupt is not available in MibSPI in compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

**NOTE:** Reading from the INTVECT0 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

**NOTE:** In multi-buffer mode, INTVECT0 contains the interrupt for the highest priority transfer group. A read from INTVECT0 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT0 and its corresponding SUSPEND flag to get loaded into SUSPEND0. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT0 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXRAM Overrun Buffer Address Register (RXOVRN\_BUF\_ADDR).

### 24.9.23 Interrupt Vector 1 (INTVECT1)

**NOTE:** The TG interrupt is not available in SPI in compatibility mode compatibility mode. Therefore, there is no possibility to access this register in compatibility mode.

**Figure 24-52. Interrupt Vector 1 (INTVECT1) [offset = 64h]**

---

**NOTE:** Reading from the INTVECT1 register when Transmit Empty is indicated does not clear the TXINTFLG flag in the SPI Flag Register (SPIFLG). Writing a new word to the SPIDATx register clears the Transmit Empty interrupt.

---

---

**NOTE:** In multi-buffer mode, INTVECT1 contains the interrupt for the highest priority transfer group. A read from INTVECT1 automatically causes the next-highest priority transfer group's interrupt status to get loaded into INTVECT1 and its corresponding SUSPEND flag to get loaded into SUSPEND1. The transfer group with the lowest number has the highest priority, and the transfer group with the highest number has the lowest priority.

Reading the INTVECT1 register when the RXOVRN interrupt is indicated in multi-buffer mode does not clear the RXOVRN flag and hence does not clear the vector. The RXOVRN interrupt vector may be cleared in multi-buffer mode either by write-clearing the RXOVRN flag in the SPI Flag Register (SPIFLG) or by reading the RXOVERN\_BUF\_ADDR register.

## 24.9.25 Parallel/Modulo Mode Control Register (SPIPMCTRL)

**NOTE:** Do not configure MODCLKPOLx and MMODEx bits since this device does not support modulo mode.

**NOTE:** The bits of this register are used in conjunction with the SPIFMTx registers. Each byte of this register corresponds to one of the SPIFMTx registers.

1. Byte0 (Bits 7:0) are used when SPIFMT0 register is selected by DFSEL[1:0] = 00 in the control field of a buffer.
2. Byte1 (Bits 15:8) are used when SPIFMT1 register is selected by DFSEL[1:0] = 01 in the control field of a buffer.
3. Byte2 (Bits 23:16) are used when SPIFMT2 register is selected by DFSEL[1:0] = 10 in the control field of a buffer.
4. Byte3 (Bits 31:24) are used when SPIFMT3 register is selected by DFSEL[1:0] = 11 in the control field of a buffer.

## 24.9.26 Multi-buffer Mode Enable Register (MIBSPIE)

### NOTE: Accessibility of Multi-Buffer RAM

The multi-buffer RAM is not accessible unless the MSPIENA bit set to 1. The only exception to this is in test mode, where, by setting RXRAMACCESS to 1, the multi-buffer RAM can be fully accessed for both read and write.

**Figure 24-55. Multi-buffer Mode Enable Register (MIBSPIE) [offset = 70h]**

| 16    | RXRAM ACCESS | 0<br>1 | Receive-RAM access control. During normal operating mode of SPI, the receive data/status portion of multi-buffer RAM is read-only. To enable testing of receive RAM, direct read/write access is enabled by setting this bit.<br>The RX portion of multi-buffer RAM is not writable by the CPU.<br>The whole of multi-buffer RAM is fully accessible for read/write by the CPU.<br><b>Note: The RX RAM ACCESS bit remains 0 after reset and it should remain cleared to 0 at all times, except when testing the RAM. SPI should be given a local reset by using the nRESET (SPIGCR0[0]) bit after RAM testing is performed so that the multi-buffer RAM gets re-initialized.</b> |
| 15-1  | Reserved     | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0     | MSPIENA      | 0<br>1 | Multi-buffer mode enable. After power-up or reset, MSPIENA remains cleared, which means that the SPI runs in compatibility mode by default. If multi-buffer mode is desired, this register should be configured first after configuring the SPIGCR0 register. If MSPIENA is not set to 1, the multi-buffer mode registers are not writable.<br>The SPI runs in compatibility mode, that is, in this mode the MibSPI is fully code-compliant to the standard device SPI. No multi-buffered-mode features are supported.<br>The SPI is configured to run in multi-buffer mode.                                                                                                     |

### NOTE: Accessibility of Registers

Registers from this offset address onwards are not accessible in SPI compatibility mode. They are accessible only in the multi-buffer mode.

### 24.9.27 TG Interrupt Enable Set Register (TGITENST)

The register TGITENST contains the TG interrupt enable flags for transfer-finished and for transfer-suspended events. Each of the enable bits in the higher half-word and the lower half-word of TGITENST belongs to one TG.

The register map shown in [Figure 24-56](#) and [Table 24-35](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 24-56. TG Interrupt Enable Set Register (TGITENST) [offset = 74h]**

## 24.9.29 Transfer Group Interrupt Level Set Register (TGITLVST)

The register TGITLVST sets the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 1.

The register map shown in [Figure 24-58](#) and [Table 24-37](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 24-58. Transfer Group Interrupt Level Set Register (TGITLVST) [offset = 7Ch]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 24-37. Transfer Group Interrupt Level Set Register (TGITLVST) Field Descriptions**

| Bit   | Field           | Value | Description                                                                                                    |

| 15-0  | SETINTLVLSUS[n] |       | Transfer-group suspended interrupt level set. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.   |
|       |                 | 0     | Read: The TGx-suspended interrupt is set to INT0.<br>Write: A write of 0 to this bit has no effect.            |
|       |                 | 1     | Read: The TGx-suspended interrupt is set to INT1.<br>Write: Set the TGx-suspended interrupt to INT1.           |

### 24.9.30 Transfer Group Interrupt Level Clear Register (TGITLVCR)

The register TGITLVCR clears the level of interrupts for transfer completed interrupt and for transfer suspended interrupt to level 0.

The register map shown in [Figure 24-59](#) and [Table 24-38](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 24-59. Transfer Group Interrupt Level Clear Register (TGITLVCR) [offset = 80h]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 24-38. Transfer Group Interrupt Level Clear Register (TGITLVCR) Field Descriptions**

| Bit   | Field           | Value | Description                                                                                                      |
|-------|-----------------|-------|------------------------------------------------------------------------------------------------------------------|
| 31-16 | CLRINTLVLRDY[n] |       | Transfer-group completed interrupt level clear. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on. |

|       |                 | 1     | Read: The TGx-completed interrupt is set to INT1.<br>Write: Clear the TGx-completed interrupt to INT0.           |
| 15-0  | CLRINTLVLSUS[n] |       | Transfer group suspended interrupt level clear. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.   |
|       |                 | 0     | Read: The TGx-suspended interrupt is set to INT0.<br>Write: A write of 0 to this bit has no effect.              |
|       |                 | 1     | Read: The TGx-suspended interrupt is set to INT1.<br>Write: Clear the TGx-suspended interrupt to INT0.           |

### 24.9.31 Transfer Group Interrupt Flag Register (TGINTFLG)

The TGINTFLG register comprises the transfer group interrupt flags for transfer-completed interrupts (INTFLGRDYx) and for transfer-suspended interrupts (INTFLGSUSx). Each of the interrupt flags in the higher half-word and the lower half-word of TGINTFLG belongs to one TG.

The register map shown in [Figure 24-60](#) and [Table 24-39](#) represents a super-set device with the maximum number of TGs (16) assumed. The actual number of bits available varies per device.

**Figure 24-60. Transfer Group Interrupt Flag Register (TGINTFLG) [offset = 84h]**

|                 |    |

| R/W1C-0         |    |

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -n = value after reset

**Table 24-39. Transfer Group Interrupt Flag Register (TGINTFLG) Field Descriptions**

| Bit   | Field        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|--------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | INTFLGRDY[n] |       | Transfer-group interrupt flag for a transfer-completed interrupt. Bit 16 corresponds to TG0, bit 17 corresponds to TG1, and so on.<br><br><b>Note: Read Clear Behavior.</b> Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGRDYx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the vector registers is 0.           |
|       |              | 0     | Read: No transfer-completed interrupt occurred since last clearing of the INTFLGRDYx flag.<br>Write: A write of 0 to this bit has no effect.                                                                                                                                                                                                                                                                                        |
|       |              | 1     | Read: A transfer finished interrupt from transfer group x occurred. No matter whether the interrupt is enabled or disabled (INTENRDYx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGRDYx is set right after the transfer from TGx is finished.<br>Write: The corresponding bit flag is cleared.                                                                                                           |
| 15-0  | INTFLGSUS[n] |       | Transfer-group interrupt flag for a transfer-suspend interrupt. Bit 0 corresponds to TG0, bit 1 corresponds to TG1, and so on.<br><br><b>Note: Read Clear Behavior.</b> Reading the interrupt vector registers TGINTVECT0 or TGINTVECT1 automatically clears the interrupt flag bit INTFLGSUSx referenced by the vector number given by INTVECT0/INTVECT1 bits, if the SUSPEND[0:1] bit in the corresponding vector registers is 1. |
|       |              | 0     | Read: No transfer-suspended interrupt occurred since the last clearing of the INTFLGSUSx flag.<br>Write: A write of 0 to this bit has no effect.                                                                                                                                                                                                                                                                                    |
|       |              | 1     | Read: A transfer-suspended interrupt from TGx occurred. No matter whether the interrupt is enabled or disabled (INTENSUSx = don't care) or whether the interrupt is mapped to INT0 or INT1, INTFLGSUSx is set right after the transfer from transfer group x is suspended.<br>Write: The corresponding bit flag is cleared.                                                                                                         |

### 24.9.32 Tick Count Register (TICKCNT)

One of the trigger sources for TGs is an internal periodic time trigger. This time trigger is called a tick counter and is basically a down-counter with a preload/reload value. Every time the tick counter detects an underflow it reloads the initial value and toggles the trigger signal provided to the TGs.

The trigger signal, shown in Figure 24-61 as a square wave, illustrates the different trigger event types for the TGs (for example, rising edge, falling edge, and both edges).

**Figure 24-61. Tick Counter Operation**

This register is shown in Figure 24-62 and described in Table 24-40.

**Figure 24-62. Tick Count Register (TICKCNT) [offset = 90h]**

| 14-8  | LPEND         | 0-7Fh                          | Last TG end pointer. Usually the TG end address (PEND) is inherently defined by the start value of the starting pointer of the subsequent TG (PSTART). The TG ends one word before the next TG starts (PEND[x] = PSTART[x+1] - 1). For a full configuration of MibSPI, the last TG has no subsequent TG, that is, no end address is defined. Therefore, LPEND has to be programmed to specify explicitly the end address of the last TG.<br><b>Note: When using all 8 transfer groups, program the LPEND bits to define the end of the last transfer group. When using less than 8 transfer groups, leave the LPEND bits programmed to point to the end of the buffer and create a dummy transfer group that defines the end of your last intentional transfer group and occupies all the remaining buffer space.</b> |

### 24.9.34 TGx Control Registers (TGxCTRL)

Each TG can be configured via one dedicated control register. The register description shows one control register (x) that is identical for all TGs. For example, the control register for TG2 is named TG2CTRL and is located at *base address + 98h + 4 × 2*. The actual number of available control registers varies by device.

| 31  | TGENA                | 0<br>1 | TGx enable.<br><br>If the correct event (TRIGEV <sub>x</sub> ) occurs at the selected source (TRIGSRC <sub>x</sub> ), a group transfer is initiated if no higher-priority TG is in active-transfer mode or if one or more higher-priority TGs are in transfer-suspend mode.<br><br>Disabling a TG while a transfer is ongoing will finish the ongoing word transfer but not the whole group transfer.<br><br>0<br>TGx is disabled.<br>1<br>TGx is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 30  | ONESHOT <sub>x</sub> | 0<br>1 | Single transfer for TGx.<br><br>0<br>TGx initiates a transfer every time a trigger event occurs and TGENA is set.<br>1<br>A transfer from TGx will be performed only once (one shot) after a valid trigger event at the selected trigger source. After the transfer is finished the TGENA <sub>x</sub> control bit will be cleared and therefore no additional transfer can be triggered before the host enables the TG again. This one shot mode ensures that after one group transfer the host has enough time to read the received data and to provide new transmit data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 29  | PRST <sub>x</sub>    | 0<br>1 | TGx pointer reset mode. Configures the way to resolve trigger events during an ongoing transfer. This bit is meaningful only for level-triggered TGs. Edge-triggered TGs cannot be restarted before their completion by another edge. The PRST bit will have no effect on this behavior.<br><br><b>Note: When the PRST bit is set, if the buffer being transferred at the time of a new trigger event is a LOCK, CSHOLD or NOBRK buffer, then only after finishing those transfers, the TG will be restarted. This means that even if the TG is retriggered, the TG will only be restarted after finishing the transfer of the first non-LOCK or non-CSHOLD buffer. In the case of the NOBRK buffer, after completing the ICOUNT number of transfers, the TG will be restarted from its PSTART.</b><br><br>This means that TX control fields such as LOCK and CSHOLD, and DMA control fields such as NOBRK have higher priority over anything else. They have the capability to delay the restart of the TG even if it is retriggered when PRST is 1.<br><br>0<br>If a trigger event occurs during a transfer from TGx, the event is ignored and is not stored internally. The TGx transfer has priority over additional trigger events.<br>1<br>The TGx pointer (PCURRENT <sub>x</sub> ) will be reset to the start address (PSTART <sub>x</sub> ) when a valid trigger event occurs at the selected trigger source while a transfer from the same TG is ongoing. Every trigger event resets PCURRENT <sub>x</sub> no matter whether the concerned TG is in transfer mode or not. The trigger events have priority over the ongoing transfer. |
| 28  | TGTD <sub>x</sub>    | 0<br>1 | TG triggered.<br><br>0<br>TGx has not been triggered or is no longer waiting for service.<br>1<br>TGx has been triggered and is either currently being serviced or waiting for servicing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 23-20 | TRIGEVTx |       | <p>Type of trigger event. A level-triggered TG can be stopped by de-activating the level trigger. However, the following restrictions apply.</p> <ul style="list-style-type: none"> <li>Deactivating the level trigger for a TG during a NOBRK transfer does not stop the transfers until all of the ICOUNT number of buffers are transferred for the NOBRK buffer. Once a NOBRK buffer is prefetched, the trigger event loses control over the TG until the NOBRK buffer transfer is completed.</li> <li>Once the transfer of a buffer with CSHOLD or LOCK bit set starts, deactivating the trigger level does not stop the transfer until the sequencer completes the transfer of the next non-CSHOLD or non-LOCK buffer in the same TG.</li> <li>Once the last buffer in a TG is pre-fetched, deactivating the trigger level does not stop the transfer group until the last buffer transfer is completed. This means even if the trigger level is deactivated at the beginning of the penultimate (one-before-last) buffer transfer, the sequencer continues with the same TG until it is completed.</li> </ul> |
|       |          | 0     | never<br>Never trigger TGx. This is the default value after reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|       |           | Fh    | TICK Internal periodic event trigger. The tick counter can initiate periodic group transfers.                                                                                                                                                                                                                                                                                                                                          |
| 15    | Reserved  | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                 |
| 14-8  | PSTARTx   | 0-7Fh | TG start address. PSTARTx stores the start address of the corresponding TG. The corresponding end address is inherently defined by the subsequent TG start address minus 1 (PENDx[TGx] = PSTARTx[TGx+1]-1). PSTARTx is copied into PCURRENTx when: <ul style="list-style-type: none"> <li>The TG is enabled</li> <li>The end of the TG is reached during a transfer</li> <li>A trigger event occurs while PRST is set to 1</li> </ul>  |
| 7     | Reserved  | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6-0   | PCURRENTx | 0-7Fh | Pointer to current buffer. PCURRENT is read-only. PCURRENTx stores the address (0...127) of the buffer that corresponds to this TG. If the TG switches from active-transfer mode to suspend-to-wait mode, PCURRENTx contains the address of the currently suspended word. After the TG resumes from suspend-to-wait mode, the next buffer will be transferred; that is, no buffer data is transferred because of suspend-to-wait mode. |

**NOTE: Register bits vary by device**

TG0 has the highest priority and TG15 has the lowest priority. Under the following conditions, a lower-priority TG cannot be interrupted by a higher-priority TG:

1. When there is a CSHOLD or LOCK buffer, until the completion of the next buffer transfer that is a non-CSHOLD or non-LOCK buffer.
2. An entire sequence of words transferred for a NOBRK DMA buffer.
3. Once the last word in a TG is pre-fetched.

### 24.9.35 DMA Channel Control Register (DMAxCTRL)

Each DMA channel can be configured via one dedicated control register. The register description below shows one exemplary control register that is identical for all DMA channels; for example, the control register for DMA channel 0 is named DMA0CTRL. The MibSPI supports up to 8 bidirectional DMA channels.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA channel control registers may vary.

**Table 24-43. DMA Channel Control Register (DMAxCTRL) Field Descriptions**

| Bit   | Field      | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | ONESHOT    | <p>0</p> <p>1</p> | <p>Auto-disable of DMA channel after ICOUNT + 1 transfers.</p> <p><b>Note: This ONESHOT applies to the DMA channel identified by x and will autotisable based on ICOUNTx.</b></p> <p>The length of the block transfer is fully controlled by the DMA controller. The enable bits RXDMAENAx and TXDMAENAx are not modified by the MibSPI.</p> <p>ONESHOT allows a block transfer of defined length (ICOUNTx + 1), mainly controlled by the MibSPI and not by the DMA controller. After ICOUNTx + 1 transfers, the enable bits RXDMAENAx and TXDMAENAx are automatically cleared by the MibSPI, hence no more DMA requests are generated. In conjunction with NOBRKx, a burst transfer can be initiated without any other transfer through another buffer.</p> |
| 30-24 | BUFIDx     | 0-7Fh             | Buffer utilized for DMA transfer. BUFIDx defines the buffer that is utilized for the DMA transfer. In order to synchronize the transfer with the DMA controller with the NOBRK condition the "suspend to wait until..." modes must be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 23-20 | RXDMA_MAPx | 0-Fh              | <p>Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. RXDMA_MAPx defines the number of the physical DMA Request line that is connected to the receive path of the MibSPI DMA channel.</p> <p>If RXDMAENAx and TXDMAENAx are both set to 1, then RXDMA_MAPx shall differ from TXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.</p>                                                                                                                                                                                                                    |
| 19-16 | TXDMA_MAPx | 0-Fh              | <p>Each MibSPI DMA channel can be linked to two physical DMA Request lines of the DMA controller. One request line for receive data and the other for request line for transmit data. TXDMA_MAPx defines the number of the physical DMA Request line that is connected to the transmit path of the MibSPI DMA channel.</p> <p>If RXDMAENAx and TXDMAENAx are both set to 1, then TXDMA_MAPx shall differ from RXDMA_MAPx and shall differ from any other used physical DMA Request line. Otherwise, unexpected interference may occur.</p>                                                                                                                                                                                                                   |
| 15    | RXDMAENAx  | <p>0</p> <p>1</p> | <p>Receive data DMA channel enable.</p> <p>No DMA request upon new receive data.</p> <p>The physical DMA channel for the receive path is enabled. The first DMA request pulse is generated after the first transfer from the referenced buffer (BUFIDx) is finished. The buffer should be configured in as "skip until RXEMPTY is set" or "suspend to wait until RXEMPTY is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.</p>                                                                                                                                                                                                                                                                                 |

**Table 24-43. DMA Channel Control Register (DMAxCTRL) Field Descriptions (continued)**

| Bit  | Field        | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 14   | TXDMAENAx    | 0<br>1 | <p>Transmit data DMA channel enable.</p> <p>0<br/>No DMA request upon new transmit data.</p> <p>1<br/>The physical DMA channel for the transmit path is enabled. The first DMA request pulse is generated right after setting TXDMAENAx to load the first transmit data. The buffer should be configured in the as "skip until TXFULL is set" or "suspend to wait until TXFULL is set" in order to ensure synchronization between the DMA controller and the MibSPI sequencer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 13   | NOBRKx       | 0<br>1 | <p>Non-interleaved DMA block transfer. This bit is available in master mode only.</p> <p><b>Note: Special Conditions during a NOBRK Buffer Transfer. If a NOBRK DMA buffer is currently being serviced by the sequencer, then it is not allowed to be disabled prematurely.</b></p> <p>During a NOBRK transfer, the following operations are not allowed:</p> <ul style="list-style-type: none"> <li>• Clearing the NOBRKx bit to 0</li> <li>• Clearing the RXDMAENAx to 0 (if it is already 1)</li> <li>• Clearing the TXDMAENAx to 0 (if it is already 1)</li> <li>• Clearing the BUFMODE[2:0] bits in TXRAM to 000</li> </ul> <p><b>Note: Any attempts to perform these actions during a NOBRK transfer will produce unpredictable results.</b></p> <p>0<br/>DMA transfers through the buffer referenced by BUFIDx are interleaved by data transfers from other active buffers or TGs. Every time the sequencer checks the DMA buffer, it performs one transfer and then steps to the next buffer.</p> <p>1<br/>NOBRKx ensures that ICOUNTx + 1 data transfers are performed from the buffer referenced by BUFIDx without a data transfer from any other buffer. The sequencer remains at the DMA buffer until ICOUNTx + 1 transfers have been processed. For example, this can be used to generate a burst transfer to one device without disabling the chip select signal in-between (the concerned buffer has to be configured with CSHOLD = 1). Another example would be to have a defined block data transfer in slave mode, synchronous to the master SPI.</p> <p><b>Note: Triggering of higher priority TGs or enabling of higher priority DMA channels will not interrupt a NOBRK block transfer.</b></p> |
| 12-8 | ICOUNTx      | 0-1Fh  | <p>Initial count of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfers equals ICOUNTx plus 1.</p> <p>If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the DMA channels. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer. If ONESHOTx and NOBRKx are not set, ICOUNTx should be 0.</p> <p><b>Note: See <a href="#">Section 24.9.36 (ICOUNT)</a> and <a href="#">Section 24.9.37 (DMACNTLEN)</a> about how to increase the ICOUNT to a 16-bit value. With this extended capability, MibSPI can transfer a block of up to 65535 (65K) words without interleaving (if NOBRK is used) or without deasserting the chip select between the buffers (if CSHOLD is used).</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

This field contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set.</p> <p><b>Note: If the TX and RX DMA requests are enabled, the COUNT register will be decremented when the RX has been serviced.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 24.9.36 DMAxCOUNT Register (ICOUNT)

**NOTE:** These registers are used only if the LARGE COUNT bit in the DMACNTLEN register is set.

The number of bidirectional DMA channels varies by device. The number of DMA channels and hence the number of DMA registers varies by device.

**Figure 24-66. DMAxCOUNT Register (ICOUNT) [offset = F8h-114h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 24-44. MibSPI DMAxCOUNT Register (ICOUNT) Field Descriptions**

| Bit   | Field   | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|---------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | ICOUNTx | 0-FFFFh | Initial number of DMA transfers. ICOUNTx is used to preset the transfer counter COUNTx. Every time COUNTx hits 0, it is reloaded with ICOUNTx. The real number of transfer equals ICOUNTx plus 1. If ONESHOTx is set, ICOUNTx defines the number of DMA transfers that are performed before the MibSPI automatically disables the corresponding DMA channel. If NOBRKx is set, ICOUNTx defines the number of DMA transfers that are performed in one sequence without a transfer from any other buffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 15-0  | COUNTx  | 0-FFFFh | Actual number of remaining DMA transfers. COUNTx Contains the actual number of DMA transfers that remain, until the DMA channel is disabled, if ONESHOTx is set. Since the real counter value is always ICOUNTx +1, the 17th bit of COUNTx is available on DMACTRLx[6] bit.<br><br><b>Note: Usage Tip for Block Transfer Using a Single DMA Request.</b> It is possible to use the multi-buffer RAM to transfer chunks of data to/from an external SPI. A DMA Controller can be used to handle the data in bursts. Suppose a chunk of 64 bytes of data needs to be transferred and a single DMA request needs to be generated at the end of transferring the 64 bytes. This can be easily achieved by configuring a TG register for the 64 buffer locations and using the DMAxCTRL/DMAxCOUNT registers to configure the last buffer (64th) of the TG as the BUFID and enable RXDMA (NOBRK = 0). At the end of the transfer of the 64th buffer, a DMA request will be generated on the selected DMA request channel. The DMA controller can do a burst read of all 64 bytes from RXRAM and/or then do a burst write to all 64 bytes to the TXRAM for the next chunk. |

### 24.9.37 DMA Large Count (DMACNTLEN)

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved    | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                            |
| 0    | LARGE_COUNT | 0     | Select either the 16-bit DMAxCOUNT counters or the smaller counters in DMAxCTRL. Select the DMAxCTRL counters. Writes to the DMAxCTRL register will modify the ICOUNT value. Reading ICOUNT and COUNT can be done from the DMAxCTRL register. The DMAxCOUNT register should not be used since any write to this register will be overwritten by a subsequent write to the DMAxCTRL register to set the TXDMAENA or RXDMAENA bits. |
|      |             | 1     | Select the DMAxCOUNT counters. Writes to the DMAxCTRL register will not modify the ICOUNT value. The ICOUNT value must be written to in the DMAxCOUNT register before the RXDMAENA or TXDMAENA bits are set in the DMAxCTRL register. The DMAxCOUNT register should be used for reading COUNT or ICOUNT.                                                                                                                          |

| 31-10 | Reserved  | 0         | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 9-0   | OVERADDR1 | 200h-3FFh | <p>Uncorrectable parity error address for RXRAM. This register holds the address where a parity error is generated while reading RXRAM. Only the CPU or DMA can read from RXRAM locations. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of RXRAM varies from 200h-3FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset or even power-on reset.</p> <p>A read operation to this register clears its contents to the default value 200h. After a power-on reset the contents will be unpredictable. A read operation can be performed after power-up to keep the register at its default value, if required. However, the contents of this register are meaningful only when EDFLG1 is set to 1.</p> <p><b>Note: A read of the UERRADDR1 register will clear EDFLG1 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR1 register does not clear EDFLG1.</b></p> |

### 24.9.41 TXRAM Uncorrectable Parity Error Address Register (UERRADDR0)

| 8-0  | UERRADDR0 | 0-1FFh | <p>Uncorrectable parity error address for TXRAM. This register holds the address where a parity error is generated while reading from TXRAM. The TXRAM can be read either by CPU or by the MibSPI sequencer logic for transmission. The address captured is byte-aligned. This error address is frozen from being updated until it is read by the CPU. The offset address of TXRAM varies from 0-1FFh.</p> <p>The register does not clear its contents during or after module-level reset, system-level reset, or even power-on reset.</p> <p>A read operation to this register clears its contents to all 0s. After a power-on reset, the contents of this register will be unpredictable. A read operation can be performed after power-up to clear the this register's contents, if required. However, the contents of this register are meaningful only when EDFLG0 is set to 1.</p> <p><b>Note: A read from the UERRADDR0 register will clear EDFLG0 in the UERRSTAT register. However, in emulation mode when the SUSPEND signal is high, a read from the UERRADDR0 register does not clear EDFLG0.</b></p> |

#### 24.9.42 RXRAM Overrun Buffer Address Register (RXOVRN BUF ADDR)

In multi-buffer mode, if a particular RXRAM location is written by the MibSPI sequencer logic after the completion of a new transfer when that location already contains valid data, the RX\_OVR bit will be set to 1 while the data is being written. The RXOVRN\_BUF\_ADDR register captures the address of the RXRAM location for which a receiver overrun condition occurred.

**Figure 24-72. RXRAM Overrun Buffer Address Register (RXOVRN BUF ADDR) [offset = 130h]**

| 9-0   | RXOVRN_BUF_ADDR | 200h-3FCh | <p>Address in RXRAM at which an overwrite occurred. This address value will show only the offset address of the RAM location in the multi-buffer RAM address space. Refer to the device-specific data sheet for the actual absolute address of RXRAM.</p> <p>This word-aligned address can vary from 200h-3FCh. Contents of this register are valid only when any of the INTVECT0 or INTVECT1 and SPIFLG registers show an RXOVRN error vector while in multi-buffer mode. If there are multiple overrun errors, then this register holds the address of first overrun address until it is read.</p> <p><b>Note: Reading this register clears the RXOVRN interrupt flag in the SPIFLG register and the TGINTVECTx.</b></p> <p><b>Note: Receiver overrun errors in multi-buffer mode can be completely avoided by using the SUSPEND until RXEMPTY feature, which can be programmed into each buffer of any TG. However, using the SUSPEND until RXEMPTY feature will make the sequencer wait until the current RXRAM location is read by the VBUS master before it can start the transfer for the same buffer location again. This may affect the overall throughput of the SPI transfer. By enabling the interrupt on RXOVRN in multi-buffer mode, the user can rely on interrupts to know if a receiver overrun has occurred. The address of the overrun in RXRAM is indicated in this RXOVRN_BUF_ADDR register.</b></p> |

### 24.9.43 I/O-Loopback Test Control Register (IOLPBKTSTCR)

This register controls test mode for I/O pins. It also controls whether loop-back should be digital or analog. In addition, it contains control bits to induce error conditions into the module. These are to be used only for module testing.

All of the control/status bits in this register are valid only when the IOLPBKTSTENA field is set to Ah.

| Bit   | Field        | Value | Description                                                                                                                                                                                                                                                                                                                                |
|-------|--------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved     | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                     |
| 24    | SCS FAIL FLG | 0     | Bit indicating a failure on <u>SPICS</u> pin compare during analog loopback.<br>Read: No mismatches occurred on any of the eight chip select pins (vs. the internal chip select number CSNR during transfers).<br>Write: Writing a 0 to this bit has no effect.                                                                            |
|       |              | 1     | Read: A comparison between the internal CSNR field and the analog looped-back value of one or more of the <u>SPICS</u> pins failed. A stuck-at fault is detected on one of the <u>SPICS</u> pins. Comparison is done only on the pins that are configured as functional and during transfer operation.<br>Write: This flag bit is cleared. |
| 23-21 | Reserved     | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                     |
| 20    | CTRL BITERR  | 0     | Controls inducing of BITERR during I/O loopback test mode.<br>Do not interfere with looped-back data.                                                                                                                                                                                                                                      |
|       |              | 1     | Induces bit errors by inverting the value of the incoming data during loopback.                                                                                                                                                                                                                                                            |
| 19    | CTRL DESYNC  | 0     | Controls inducing of the desync error during I/O loopback test mode.<br>Do not cause a desync error.                                                                                                                                                                                                                                       |
|       |              | 1     | Induce a desync error by forcing the incoming <u>SPIENA</u> pin (if functional) to remain 0 even after the transfer is complete. This forcing will be retained until the kernel reaches the idle state.                                                                                                                                    |
| 18    | CTRL PARERR  | 0     | Controls inducing of the parity errors during I/O loopback test mode.<br>Do not cause a parity error.                                                                                                                                                                                                                                      |
|       |              | 1     | Induce a parity error by inverting the polarity of the parity bit.                                                                                                                                                                                                                                                                         |
| 17    | CTRL TIMEOUT | 0     | Controls inducing of the timeout error during I/O loopback test mode.<br>Do not cause a timeout error.                                                                                                                                                                                                                                     |
|       |              | 1     | Induce a timeout error by forcing the incoming <u>SPIENA</u> pin (if functional) to remain 1 when transmission is initiated. The forcing will be retained until the kernel reaches the idle state.                                                                                                                                         |

**Table 24-51. I/O-Loopback Test Control Register (IOLPBKTSTCR) Field Descriptions (continued)**

| Bit   | Field            | Value                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

#### 24.9.44 SPI Extended Prescale Register 1 (EXTENDED\_PRESCALE1 for SPIFMT0 and SPIFMT1)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT0 and SPIFMT1 registers. For example, EPRESCALE\_FMT1[7:0] of EXTENDED\_PRESCALE1 and PRESCALE1 of SPIFMT1 register will always reflect the same contents. Similarly, EPRESCALE\_FMT0[7:0] and PRESCALE0 of SPIFMT0 reflect the same contents.

**Figure 24-74. SPI Extended Prescale Register 1 (EXTENDED\_PRESCALE1 for SPIFMT0 and SPIFMT1) [offset = 138h]**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 26-16 | EPRESCALE_FMT1 | 0-7FFh | <p>EPRESCALE_FMT1. Extended Prescale value for SPIFMT1. EPRESCALE_FMT1 determines the bit transfer rate of data format 1 if the SPI/MibSPI is the network master. EPRESCALE_FMT1 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT1 <b>does not need</b> to be configured. These EPRESCALE_FMT1[7:0] bits and PRESCALE1 bits of SPIFMT1 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format1} = VCLK / (EPRESCALE_FMT1 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE1 bits of SPIFMT1 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE1[26:16] or SPIFMT1[15:8] register.</p> <p><b>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT1 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE1 field of SPIFMT1 will automatically clear EPRESCALE_FMT1[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</b></p> |

| Bit  | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10-0 | EPRESCALE_FMT0 | 0-7FFh | <p>EPRESCALE_FMT0. Extended Prescale value for SPIFMT0. EPRESCALE_FMT0 determines the bit transfer rate of data format 0 if the SPI/MibSPI is the network master. EPRESCALE_FMT0 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT0 <b>does not need</b> to be configured. These EPRESCALE_FMT0[7:0] bits and PRESCALE0 bits of SPIFMT0 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{Format0} = VCLK / (EPRESCALE\_FMT0 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE0 bits of SPIFMT0 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE0[10:0] or SPIFMT0[15:8] register.</p> <p><b>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE1 register is programmed after SPIFMT0 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE1 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE0 field of SPIFMT0 will automatically clear EPRESCALE_FMT0[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</b></p> |

### 24.9.45 SPI Extended Prescale Register 2 (EXTENDED\_PRESCALE2 for SPIFMT2 and SPIFMT3)

This register provides an extended Prescale values for SPICLK generation to be able to interface with much slower SPI Slaves. This is an extension of SPIFMT2 and SPIFMT3 registers. For example, EPRESCALE\_FMT3[7:0] of EXTENDED\_PRESCALE2 and PRESCALE3 of SPIFMT3 register will always reflect the same contents. Similarly, EPRESCALE\_FMT2[7:0] and PRESCALE2 of SPIFMT2 reflect the same contents.

| 31-27 | Reserved       | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 26-16 | EPRESCALE_FMT3 | 0-7FFh | <p>EPRESCALE_FMT3. Extended Prescale value for SPIFMT3. EPRESCALE_FMT3 determines the bit transfer rate of data format 3 if the SPI/MibSPI is the network master. EPRESCALE_FMT3 is used to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT3 <b>does not need</b> to be configured. These EPRESCALE_FMT3[7:0] bits and PRESCALE3 bits of SPIFMT3 register will point to the same physically implemented register. The clock rate for data format 1 can be calculated as:</p> $BR_{Format3} = VCLK / (EPRESCALE_FMT3 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE3 bits of SPIFMT3 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE3[26:16] or SPIFMT3[15:8] register.</p> <p><b>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT3 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE3 field of SPIFMT3 will automatically clear EPRESCALE_FMT3[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</b></p> |

| 10-0 | EPRESCALE_FMT2 | 0-7FFh | <p>EPRESCALE_FMT2. Extended Prescale value for SPIFMT2. EPRESCALE_FMT2 determines the bit transfer rate of data format 2 if the SPI/MibSPI is the network master. EPRESCALE_FMT2 is use to derive SPICLK from VCLK. If the SPI is configured as slave, EPRESCALE_FMT2 <b>does not need</b> to be configured. These EPRESCALE_FMT2[7:0] bits and PRESCALE2 bits of SPIFMT2 register will point to the same physically implemented register. The clock rate for data format 0 can be calculated as:</p> $BR_{Format2} = VCLK / (EPRESCALE\_FMT2 + 1)$ <p>Write: This register field should be written if a SPICLK prescaler of more VCLK/256 is required. This field provides a prescaler of up to VCLK/2048 for SPICLK. Writing to this register field will also get reflected in the PRESCALE2 bits of SPIFMT2 register.</p> <p>Read: Reading this field will reflect the PRESCALE value based on the last written register field, that is, EXTENDED_PRESCALE2[10:0] or SPIFMT2[15:8] register.</p> <p><b>Note: If Extended Prescaler is required, it should be ensured that EXTENDED_PRESCALE2 register is programmed after SPIFMT2 register is programmed. This is to ensure that the final SPICLK prescale value is controlled by EXTENDED_PRESCALE2 register when a prescale of more 256 is intended on SPICLK. Writing to PRESCALE2 field of SPIFMT2 will automatically clear EPRESCALE_FMT2[10:8] bits to 000 so that the integrity of PRESCALE value is maintained.</b></p> |

## 24.10 Multi-Buffer RAM

The multi-buffer RAM is used for holding transit and received data, control and status information. The multi-buffer RAM contains two banks of up to 128 32-bit words for a maximum configuration. One bank (TXRAM) contains entries for transmit data (replicating the SPIDAT1 register). The other bank (RXRAM) contains received data (replicating the SPIBUF register). The buffers can be partitioned into multiple TGs, each containing a programmable number of buffers. Each of the buffers can be subdivided into 16-bit transmit field, 16-bit receive field, 16-bit control field, and 16-bit status field, as displayed in [Figure 24-76](#). A 4-bit parity field per word is also included in each bank of RAM.

**Figure 24-76. Multi-Buffer RAM Configuration**

All fields can be read and written with 8-bit, 16-bit, or 32-bit accesses.

The transmit fields can be written and read in the address range 000h to 1FFh. The transmit words contain data and control fields.

The receive RAM fields are read-only and can be accessed through the address range 200h to 3FCh. The receive words contain data and status fields.

The chip select number (CSNR) bit field of the control field for a given word is mirrored into the corresponding receive-buffer status field after transmission.

The Parity is automatically calculated and copied to Parity location

**NOTE:** Please refer to the specific device datasheet for the actual number of transmit and receive buffers.

Write to unimplemented buffer is overwriting the corresponding implemented buffer. In MIBSPI, if the RAM SIZE specified is 32 buffers, write to 33rd buffer overwrites 1st buffer, write to 34th buffer overwrites 2nd buffer and so on.

### 24.10.1 Multi-Buffer RAM Auto Initialization

When the MIBSPI is out of reset mode, auto initialization of multi-buffer RAM starts. The application code must check for BUFINITACTIVE bit to be 0 (Multi-buffer RAM initialization is complete) before configuring multi-buffer RAM.

Besides the default auto initialization after reset, the auto-initialization sequence can also be done by:

1. Enable the global hardware memory initialization key by programming a value of 1010b to the bits [3:0] of the MINITGCR register of the System module.
2. Set the control bit for the multi-buffer RAM in the MSINENA System module register. This bit is device-specific for each memory that support auto-initialization. Please refer to the device datasheet to identify the control bit for the multi-buffer RAM. This starts the initialization process. The BUFINITACTIVE bit will get set to reflect that the initialization is ongoing.
3. When the memory initialization is completed, the corresponding status bit in the MINISTAT register will be set. Also, the BUFINITACTIVE bit will get cleared.
4. Disable the global hardware memory initialization key by programming a value of 0101 to the bits [3:0] of the MINITGCR register of the System module.

Please refer to the *Architecture* chapter for more details on the memory auto-initialization process.

---

**NOTE:** During Auto Initialization process, all the Multi-buffer mode registers (except MIBSPIE) will be reset to their default values. So, it should be ensured that Auto Initialization is completed before configuring the Multi-buffer mode registers.

---

### 24.10.2 Multi-Buffer RAM Register Summary

This section describes the multi-buffer RAM control and transmit-data fields of each word of TXRAM, and the status and receive-data fields of each word of RXRAM. The base address for multi-buffer RAM is FF0E 0000h for MibSPI1 RAM, FF0C 000h for MibSPI3 RAM, and FF0A 0000h for MibSPI5 RAM.

**Table 24-54. Multi-Buffer RAM Register Summary**

| Offset           | Acronym | Register Description                     | Section                         |
|------------------|---------|------------------------------------------|---------------------------------|
| Base + 0h-1FFh   | TXRAM   | Multi-Buffer RAM Transmit Data Register  | <a href="#">Section 24.10.3</a> |
| Base + 200h-3FFh | RXRAM   | Multi-Buffer RAM Receive Buffer Register | <a href="#">Section 24.10.4</a> |

### 24.10.3 Multi-Buffer RAM Transmit Data Register (TXRAM)

Each word of TXRAM is a transmit-buffer register.

**NOTE:** Writing to only the control fields, bits 28 through 16, does not initiate any SPI transfer in master mode. This feature can be used to set up SPICLK phase or polarity before actually starting the transfer by only updating the DFSEL bit field to select the required phase and polarity combination.

| Bit   | Field   | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|---------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-29 | BUFMODE |       | Specify conditions that are recognized by the sequencer to initiate transfers of each buffer word. When one of the "skip" modes is selected, the sequencer checks the buffer status every time it reads from this buffer. If the current buffer status (TXFULL, RXEMPTY) does not match, the buffer is skipped without a data transfer.<br><br>When one of the "suspend" modes is selected, the sequencer checks the buffer status when it reads from this buffer. If TxFULL and/or RXEMPTY do not match, the sequencer waits until a match occurs. No data transfer is initiated until the status condition of this buffer changes. |
|       |         | 0     | <b>disabled.</b> The buffer is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|       |         | 1h    | <b>skip single-transfer mode.</b> Skip this buffer until the corresponding TxFULL flag is set (new transmit data is available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|       |         | 2h    | <b>skip overwrite-protect mode.</b> Skip this buffer until the corresponding RXEMPTY flag is set (new receive data can be stored in RXDATA without data loss).                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|       |         | 3h    | <b>skip single-transfer overwrite-protect mode.</b> Skip this buffer until both of the corresponding TxFULL and RXEMPTY flags are set. (new transmit data available and previous data received by the host).                                                                                                                                                                                                                                                                                                                                                                                                                         |
|       |         | 4h    | <b>continuous mode.</b> Initiate a transfer each time the sequencer checks this buffer. Data words are retransmitted if the buffer has not been updated. Receive data is overwritten, even if it has not been read.                                                                                                                                                                                                                                                                                                                                                                                                                  |
|       |         | 5h    | <b>suspend single-transfer mode.</b> Suspend-to-wait until the corresponding TxFULL flag is set (the sequencer stops at the current buffer until new transmit data is written in the TXDATA field).                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|       |         | 6h    | <b>suspend overwrite-protect mode.</b> Suspend-to-wait until the corresponding RXEMPTY flag is set (the sequencer stops at the current buffer until the previously-received data is read by the host).                                                                                                                                                                                                                                                                                                                                                                                                                               |
|       |         | 7h    | <b>suspend single-transfer overwrite-protect mode.</b> Suspend-to-wait until the corresponding TxFULL and RXEMPTY flags are set (the sequencer stops at the current buffer until new transmit data is written into the TXDATA field and the previously-received data is read by the host).                                                                                                                                                                                                                                                                                                                                           |
| 28    | CSHOLD  |       | Chip select hold mode. The CSHOLD bit is supported in master mode only, it is ignored in slave mode. CSHOLD defines the behavior of the chip select line at the end of a data transfer.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|       |         | 0     | The chip select signal is deactivated at the end of a transfer after the T2CDELAY time has passed. If two consecutive transfers are dedicated to the same chip select this chip select signal will be deactivated for at least 2VCLK cycles before it is activated again.                                                                                                                                                                                                                                                                                                                                                            |
|       |         | 1     | The chip select signal is held active at the end of a transfer until a control field with new data and control information is loaded into SPIDAT1. If the new chip select number equals the previous one, the active chip select signal is extended until the end of transfer with CSHOLD cleared, or until the chip-select number changes.                                                                                                                                                                                                                                                                                          |

**Table 24-55. Multi-Buffer RAM Transmit Data Register (TXRAM) Field Descriptions (continued)**

| Bit   | Field  | Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

<sup>(1)</sup> If your MibSPI does not have this chip select pin, this bit is 0.

## 24.10.4 Multi-Buffer RAM Receive Buffer Register (RXRAM)

Each word of RXRAM is a receive-buffer register.

**Figure 24-78. Multi-Buffer RAM Receive Buffer Register (RXRAM)**

| 31  | RXEMPTY | 0<br>1 | <p>Receive data buffer empty. When the host reads the RXDATA field or the entire RXRAM register, it automatically sets the RXEMPTY flag. When a data transfer is completed, the received data is copied into RXDATA, and the RXEMPTY flag is cleared.</p> <p>New data has been received and copied into RXDATA.</p> <p>No data has been received since the last read of RXDATA.</p> <p>This flag gets set to 1 under the following conditions:</p> <ul style="list-style-type: none"> <li>Reading the RXDATA field of the RXRAM register</li> <li>Writing a 1 to clear the RXINTFLG bit in the SPI Flag Register (SPIFLG)</li> </ul> <p>Write-clearing the RXINTFLG bit before reading RXDATA indicates the received data is being ignored. Conversely, RXINTFLG can be cleared by reading the RXDATA field of RXRAM (or the entire register).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30  | RXOVR   | 0<br>1 | <p>Receive data buffer overrun. When a data transfer is completed and the received data is copied into RXBUF while it is already full, RXOVR is set. Overruns always occur to RXBUF, not to RXRAM; the contents of RXRAM are overwritten only after it is read by the Peripheral (VBUSP) master (CPU, DMA, or other host processor).</p> <p>If enabled, the RXOVRN interrupt is generated when RXBUF is overwritten, and reading either SPI Flag Register (SPIFLG) or SPIVEXTx shows the RXOVRN condition. Two read operations from the RXRAM register are required to reach the overwritten buffer word (one to read RXRAM, which then transfers RXDATA into RXRAM for the second read).</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p><b>Note: A special condition under which RXOVR flag gets set. If both RXRAM and RXBUF are already full and while another buffer receive is underway, if any errors such as TIMEOUT, BITERR, and DLEN_ERR occur, then RXOVR in RXBUF and SPI Flag Register (SPIFLG) registers will be set to indicate that the status flags are getting overwritten by the new transfer. This overrun should be treated like a normal receive overrun.</b></p> <p>No receive data overrun condition occurred since last read of the data field.</p> <p>A receive data overrun condition occurred since last read of the data field.</p> |
| 29  | TXFULL  | 0<br>1 | <p>Transmit data buffer full. This flag is a read-only flag. Writing into the SPIDAT0 or SPIDAT1 field while the TX shift register is full will automatically set the TXFULL flag. Once the word is copied to the shift register, the TXFULL flag will be cleared. Writing to SPIDAT0 or SPIDAT1 when both TXBUF and the TX shift register are empty does not set the TXFULL flag.</p> <p>The transmit buffer is empty; SPIDAT0/SPIDAT1 is ready to accept a new data.</p> <p>The transmit buffer is full; SPIDAT0/SPIDAT1 is not ready to accept new data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 24-57. Multi-Buffer Receive Buffer Register (RXRAM) Field Descriptions (continued)**

| Bit   | Field     | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|-----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28    | BITERR    | 0<br>1  | <p>Bit error. There was a mismatch of internal transmit data and transmitted data.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p>No bit error occurred.</p> <p>A bit error occurred. The SPI samples the signal of the transmit pins (master: SIMOx, slave: SOMIx) at the receive point (one-half clock cycle after the transmit point). If the sampled value differs from the transmitted value, a bit error is detected and the BITERR flag is set. Possible reasons for a bit error include noise, an excessively high bit rate, capacitive load, or another master/slave trying to transmit at the same time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 27    | DESYNC    | 0<br>1  | <p>Desynchronization of slave device. This bit is valid in master mode only.</p> <p>The master monitors the ENA signal coming from the slave device and sets the DESYNC flag if ENA is deactivated before the last reception point or after the last bit is transmitted plus <math>t_{T2EDELAY}</math>. If DESYNCENA is set, an interrupt is asserted. Desynchronization can occur if a slave device misses a clock edge coming from the master.</p> <p><b>Note: In the Compatibility Mode MibSPI, under some circumstances it is possible for a desync error detected for the previous buffer to be visible in the current buffer. This is because the receive completion flag/interrupt is generated when the buffer transfer is completed. But desynchronization is detected after the buffer transfer is completed. So, if the VBUS master reads the received data quickly when an RXINT is detected, then the status flag may not reflect the correct desync condition. In multi-buffer mode, the desync flag is always guaranteed to be for the current buffer.</b></p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p>No slave desynchronization is detected.</p> <p>A slave device is desynchronized.</p> |
| 26    | PARITYERR | 0<br>1  | <p>Parity error. The calculated parity differs from the received parity bit.</p> <p>If the parity generator is enabled (selected individually for each buffer) an even or odd parity bit is added at the end of a data word. During reception of the data word, the parity generator calculates the reference parity and compares it to the received parity bit. If a mismatch is detected, the PARITYERR flag is set.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p>No parity error is detected.</p> <p>A parity error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25    | TIMEOUT   | 0<br>1  | <p>Time-out because of non-activation of <math>\overline{\text{SPIEN}}_A</math> pin.</p> <p>The SPI generates a time-out when the slave does not respond in time by activating the ENA signal after the chip select signal has been activated. If a time-out condition is detected, the corresponding chip select is deactivated immediately and the TIMEOUT flag is set. In addition, the TIMEOUT flag in the status field of the corresponding buffer and in the SPI Flag Register (SPIFLG) is set.</p> <p><b>Note: This bit is valid only in master mode.</b></p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p>No <math>\overline{\text{SPIEN}}_A</math> pin time-out occurred.</p> <p>An <math>\overline{\text{SPIEN}}_A</math> signal time-out occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 24    | DLENERR   | 0<br>1  | <p>Data length error flag.</p> <p><b>Note: This flag is cleared to 0 when the RXDATA field of the RXRAM register is read.</b></p> <p>No data-length error occurred.</p> <p>A data length error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 23-16 | LCSNR     | 0-FFh   | <p>Last chip select number. LCSNR in the status field is a copy of CSNR in the corresponding control field. It contains the chip select number that was activated during the last word transfer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 15-0  | RXDATA    | 0-FFFFh | <p>SPI receive data. This is the received word, transferred from the receive shift-register at the end of a transfer. Regardless of the programmed character length and the direction of shifting, the received data is stored right-justified in the register.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 24.11 Parity Memory

The parity portion of multi-buffer RAM is not accessible by the CPU during normal operating modes. However, each read or write operation to the control/data/status portion of the multi-buffer RAM causes reads/writes to the parity portion as well.

- Each write to the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a write operation to the parity portion of RAM simultaneously to update the equivalent parity bits.
- Each read operation from the multi-buffer RAM (either from the Peripheral interface or by the MibSPI itself) causes a read operation from the parity portion of the RAM for parity comparison purpose.
- Reads/Writes to multi-buffer RAM can either be caused by any CPU/DMA accesses or by the sequencer logic of MibSPI itself.
- In case of Parity error ESM module is notified to generate MIBSPI Parity ESM interrupt. User can check the error status and address location captured in the UERRSTAT and UERRADDRx registers respectively.

For testing the parity portion of the multi-buffer RAM, which is a 4-bit field per word address (1 bit per byte), a separate parity memory test mode is available. Parity memory test mode can be enabled and disabled by the PTESTEN bit in the UERRCTRL register.

During the parity test mode, the parity locations are addressable at the address between RAM\_BASE\_ADDR + 0x400h and RAM\_BASE\_ADDR + 0x7FFh. Each location corresponds, sequentially, to each TXRAM word, then to each RXRAM word. See [Figure 24-79](#) for a diagram of the memory map of parity memory during normal operating mode and during parity test mode.

During parity test mode, after writing the data/control portion of the RAM, the parity locations can be written with incorrect parity bits to intentionally cause parity errors.

See the device-specific data sheet to get the actual base address of the multi-buffer RAM.

---

**NOTE:** The RX\_RAM\_ACCESS bit can also be set to 1 during the parity test mode to be enable writes to RXRAM locations. Both parity RAM testing and RXRAM testing can be done together.

---

There are 4 bits of parity corresponding to each of the 32-bit multi-buffer locations. Individual bits in the parity memory are byte-addressable in parity test mode. See the example in [Figure 24-80](#) for further details.

---

**NOTE:** Polarity of the parity (odd/even) varies by device. In some devices, a control register in the system module can be used to select odd or even parity.

---

**Figure 24-79. Memory Map for Parity Locations During Normal and Test Mode**

### 24.11.1 Example of Parity Memory Organization

Suppose TXBUF5 (6th location in TXRAM) in the multi-buffer RAM is written with a value of A001\_AA55. If the polarity of the parity is set to odd, the corresponding parity location parity5 will get updated with equivalent parity of 1011 in its field.

During parity-memory test mode, these bits can be individually byte addressed. The return data will be a byte adjusted with actual parity bit in the LSB of the byte. If a word is read from the word-boundary address of parity locations, then each bit of the 4-bit parity is byte-adjusted and a 32-bit word is returned. 0s will be padded into the parity bits to get each byte. See Figure 24-80 for a diagram.

**Figure 24-80. Example of Memory-Mapped Parity Locations During Test Mode**

1 Shaded areas indicate reads return 0, writes have no effect. These registers are not physically present.

#### NOTE: Read Access to Parity Memory Locations

Parity memory locations can be read even without entering into parity memory test mode. Their address remains as in memory test mode. It is only to enter parity-memory test mode to enable write access to the parity memory locations.

## 24.12 MibSPI Pin Timing Parameters

The pin timings of SPI can be classified based on its mode of operation. In each mode, different configurations like Phase and Polarity affect the pin timings.

The pin directions are based on the mode of operation.

### Master mode SPI:

- SPICLK (SPI Clock) - Output
- SPISIMO (SPI Slave In Master Out) - Output
- $\overline{\text{SPIC}}\text{S}$  (SPI Slave Chip Selects) - Output
- SPISOMI (SPI Slave Out Master In) - Input
- $\overline{\text{SPIEN}}\text{A}$  (SPI slave ready Enable) - Input

### Slave mode SPI:

- SPICLK - Input
- SPISIMO - Input
- $\overline{\text{SPIC}}\text{S}$  - Input
- SPISOMI - Output
- $\overline{\text{SPIEN}}\text{A}$  - Output

**NOTE:** All the timing diagrams given below are with Phase = 0 and Polarity = 0. unless explicitly stated otherwise.

### 24.12.1 Master Mode Timings for SPI/MibSPI

**Figure 24-81. SPI/MibSPI Pins During Master Mode 3-pin Configuration**

\* De-activation of  $\overline{\text{SPIENA}}$  pin is controlled by the Slave.

\* Dotted vertical lines indicate the receive edges

**Figure 24-84. SPI/MibSPI Pins During Master/Slave Mode with 5-pin Configuration**

\* Dotted vertical lines indicate the receive edges for the Master

\* ENABLE\_HIGHZ is cleared to 0 in Slave SPI

## 24.12.2 Slave Mode Timings for SPI/MibSPI

**Figure 24-85. SPI/MibSPI Pins During Slave Mode 3-pin Configuration**

**Figure 24-86. SPI/MibSPI Pins During Slave Mode 4-pin with  $\overline{\text{SPIENA}}$  Configuration**

**Figure 24-87. SPI/MibSPI Pins During Slave Mode in 5-pin Configuration - (Single Slave)**

**Figure 24-88. SPI/MibSPI Pins During Slave Mode in 5-pin Configuration - (Single/Multi Slave)**

### 24.12.3 Master Mode Timing Parameter Details

In case of Master, the module drives out SPICLK. It also drives out the Transmit data on SPISIMO with respect to its internal SPICLK. In case of Master mode, the RX data on the SPISOMI pin is registered with respect to SPICLK received through the input buffer from the I/O pad.

If the chip select pin is functional, then the Master will drive out the  $\overline{\text{SPICS}}$  pins before starting the SPICLK. If the  $\overline{\text{SPIENA}}$  pin is functional, then the Master will wait for an active low from the Slave on the input pin to start the SPICLK.

### 24.12.4 Slave Mode Timing Parameter Details

In case of Slave mode, the module will drive only the SPISOMI and  $\overline{\text{SPIENA}}$  pins. All other pins are inputs to it. The RX data on the SPISIMO pin will be registered with respect to the SPICLK pin. The Slave will use the  $\overline{\text{SPICS}}$  pin to drive out the  $\overline{\text{SPIENA}}$  pin if both are functional. If 4-pin with  $\overline{\text{SPIENA}}$  is configured, then the Slave will drive out an active-low signal on the  $\overline{\text{SPIENA}}$  pin when new data is written to the TX Shift Register. Irrespective of 4-pin with  $\overline{\text{SPIENA}}$  or 5-pin configuration, the Slave will deassert the  $\overline{\text{SPIENA}}$  pin after the last bit is received. If ENABLE\_HIGHZ (SPIINT0.24) bit is 0, the de-asserted value of the  $\overline{\text{SPIENA}}$  pin will be 1. Otherwise, it will depend upon the internal pull up or pull down resistor (if implemented) depending upon the Specification of the Chip.

## Serial Communication Interface (SCI)/ Local Interconnect Network (LIN) Module

This chapter describes the serial communication interface (SCI) / local interconnect network (LIN) module. The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*. This module can be configured to operate in either SCI (UART) or LIN mode.

**NOTE:** This chapter describes a superset implementation of the LIN/SCI module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

## 25.1 Introduction and Features

The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The core of the module is an SCI. The SCI's hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-master/multiple-slave with a message identification for multi-cast transmission between any network nodes.

Throughout the chapter Compatibility Mode refers to SCI Mode functionality of SCI/LIN Module. The initial part of the chapter explains about the SCI functionality and later part about the LIN functionality. Though the register are common for LIN and SCI, the register descriptions has notes to identify the register / bit usage in different modes.

### 25.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous or isosynchronous communication modes
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- At 100MHz Peripheral Clock, 3.125 Mbits/s is the Max Baud Rate achievable
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Five error flags and Seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multi-buffered receive and transmit units

---

**NOTE:** SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general purpose I/O pin.

---

### 25.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3, 2.0 and 2.1 protocols
- Configurable Baud Rate up to 20 Kbits/s
- Two external pins: LINRX and LINTX.
- Multi-buffered receive and transmit units
- Identification masks for message filtering
- Automatic master header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Slave automatic synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- $2^{31}$  programmable transmission rates with 7 fractional bits
- Wakeup on LINRX dominant level from transceiver
- Automatic wakeup support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 Interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

### 25.1.3 Block Diagram

The SCI/LIN module contains core SCI block with added sub-blocks to support LIN protocol.

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

**Transmitter (TX)** contains two major registers to perform the double- buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.

#### **Baud Clock Generator**

- A programmable baud generator produces either a baud clock scaled from VBUSP CLK.

**Receiver (RX)** contains two major registers to perform the double- buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. [Figure 25-1](#) shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multi-buffered receiver and transmitter. The SCI interface, the DMA control subblocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. [Figure 25-2](#) shows the SCI/LIN block diagram.

Figure 25-1. Detailed SCI Block Diagram

Figure 25-2. SCI/LIN Block Diagram

## 25.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

### 25.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 25-3](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 25-3](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 25-3](#) use one stop bit per frame.

**Figure 25-3. Typical SCI Data Frame Formats**

## 25.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

### 25.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises.

Figure 25-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

**Figure 25-4. Asynchronous Communication Bit Timing**

### 25.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not supported on this device because SCICLK pin is not available.**

## 25.2.3 SCI Baud Rate

The SCI/LIN has an internally-generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value of the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK \text{ Frequency} = \frac{VCLK \text{ Frequency}}{P + 1 + \frac{M}{16}}$$

$$\text{Asynchronous baud value} = \frac{SCICLK \text{ Frequency}}{16}$$

For P = 0,

$$\text{Asynchronous baud value} = \frac{VCLK \text{ Frequency}}{32} \quad (38)$$

### 25.2.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the super fractional divider uses an additional 3-bit modulating value, illustrated in Table 25-2. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ . If the character length is more than 10, then the modulation table will be a rolled-over version of the original table (Table 25-1), as shown in Table 25-2.

The baud rate will vary over a data field to average according to the BRS[30:28] value by a “d” fraction of the peripheral internal clock:  $0 < d < 1$ . Refer Figure 25-5 for a simple Average “d” calculation based on “U” value (BRS[30:28]).

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (39)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (40)$$

For P = 0  $T_{bit} = 32T_{VCLK}$

**Table 25-1. Superfractional Bit Modulation for SCI Mode (Normal Configuration)<sup>(1)</sup>**

| BRS[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |

## 25.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

### 25.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. [Figure 25-6](#) illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

**Figure 25-6. Idle-Line Multiprocessor Communication Format**

#### 25.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. [Figure 25-7](#) illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 25-7. Address-Bit Multiprocessor Communication Format**

### 25.2.5 SCI Multi-Buffered Mode

To reduce CPU load when Receiving or Transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate Receive and transmit buffers. Multi buffered mode is enabled by setting the MBUF MODE bit in the SCIGCR1 register.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) could occur after transmitting a response.

Figure 25-8 and Figure 25-9 shows the receive and transmit multi-buffer functional block diagram.

**Figure 25-8. Receive Buffers**

Figure 25-9. Transmit Buffers

## 25.3 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 25-10](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level 1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 25-10. General Interrupt Scheme**

**Figure 25-11. Interrupt Generation for Given Flags**

### 25.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 25.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

### 25.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 25.3.4 Error Interrupts

The following error detection are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register.

There are 16 interrupt sources in the SCI/LIN module, In SCI mode 8 interrupts are supported, as seen in [Table 25-4](#).

**Table 25-4. SCI/LIN Interrupts**

| Offset <sup>(1)</sup> | Interrupt                                  | Applicable to SCI | Applicable to LIN |
|-----------------------|--------------------------------------------|-------------------|-------------------|
| 0                     | No interrupt                               |                   |                   |
| 1                     | Wakeup                                     | Yes               | Yes               |
| 2                     | Inconsistent-synch-field error             | No                | Yes               |
| 3                     | Parity error                               | Yes               | Yes               |
| 4                     | ID                                         | No                | Yes               |
| 5                     | Physical bus error                         | No                | Yes               |
| 6                     | Frame error                                | Yes               | Yes               |
| 7                     | Break detect                               | Yes               | No                |
| 8                     | Checksum error                             | No                | Yes               |
| 9                     | Overrun error                              | Yes               | Yes               |
| 10                    | Bit error                                  | Yes               | Yes               |
| 11                    | Receive                                    | Yes               | Yes               |
| 12                    | Transmit                                   | Yes               | Yes               |
| 13                    | No-response error                          | No                | Yes               |
| 14                    | Timeout after wakeup signal (150 ms)       | No                | Yes               |
| 15                    | Timeout after three wakeup signals (1.5 s) | No                | Yes               |
| 16                    | Timeout (Bus Idle, 4s)                     | No                | Yes               |

<sup>(1)</sup> Offset 1 is the highest priority. Offset 16 is the lowest priority.

## 25.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA transfers depending on whether multi-buffer mode bit (MBUF MODE in the SCIGCR1 register) is enabled or is not enabled. See [Chapter 26](#) for additional information.

### 25.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

In Multi-Buffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RX DMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

### 25.4.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET TX DMA/CLR TX DMA bits, respectively.

In Multi-Buffered SCI mode, once the TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis.

## 25.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 25.5.1](#) or [Section 25.5.2](#)).

### 25.5.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffer Mode

After a valid idle period is detected, data is automatically received as it arrives on the LINRX pin.

#### 25.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

### 25.5.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, interrupt, or DMA method to read the data. The SCI clears the RXRDY bit after the new data in SCIRD has been read.

## 25.5.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multi-Buffered or Buffered SCI Mode

### 25.5.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is cleared to 0. In this mode, SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

### 25.5.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, interrupt, or DMA method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. SCI waits for data to be written to the SCITD register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

## 25.6 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

### 25.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 25-12](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 25.7 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling LIN MODE bit in SCIGCR1 register.

---

**NOTE:** The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10.

---

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see [Section 25.13](#).

### 25.7.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

- i. Support for LIN 2.0 checksum
- ii. Enhanced synchronizer FSM support for frame processing
- iii. Enhanced handling of extended frames
- iv. Enhanced baudrate generator
- v. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware.

The Master Mode of LIN module is compatible with LIN 2.1 standard.

## 25.7.2 Message Frame

The LIN protocol defines a message frame format, illustrated in Figure 25-12. Each frame includes one master header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces may be 0.

There is no arbitration in the definition of the LIN protocol; therefore, multiple slave nodes responding to a header might be detected as an error.

The LIN bus is a single channel wired-AND. The bus has a binary level: either dominant for a value of 0, or recessive for a value of 1.

**Figure 25-12. LIN Protocol Message Frame Format: Master Header and Slave Response**

### 25.7.2.1 Message Header

The header of a message is initiated by a master (see Figure 25-13) and consists of a three field-sequence:

- The synch break field signaling the beginning of a message
- The synch field conveying bit rate information of the LIN bus
- The ID field denoting the content of a message

**Figure 25-13. Header 3 Fields: Synch Break, Synch, and ID**

## 25.7.2.2 Response

The format of the response is as illustrated in [Figure 25-14](#). There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

**Figure 25-14. Response Format of LIN Message Frame**

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames ([Section 25.7.6](#)). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see [Table 25-5](#), or by LENGTH value in SCIFORMAT[18:16] register; see [Table 25-6](#). The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

**Table 25-5. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than 1.3**

| ID5 | ID4 | Number of Data bytes |
|-----|-----|----------------------|
| 0   | 0   | 2                    |
| 0   | 1   | 2                    |
| 1   | 0   | 4                    |
| 1   | 1   | 8                    |

**Table 25-6. Response Length with SCIFORMAT[18:16] Programming**

| SCIFORMAT[18:16] | No. of Bytes |
|------------------|--------------|
| 000              | 1            |
| 001              | 2            |
| 010              | 3            |
| 011              | 4            |
| 100              | 5            |
| 101              | 6            |
| 110              | 7            |
| 111              | 8            |

### 25.7.3 Synchronizer

The synchronizer has three major functions in the messaging between master and slave nodes. It generates the master header data stream, it synchronizes to the LIN bus for responding, and it locally detects timeouts. A bit rate is programmed using the prescalers in the BRS register to match the indicated LIN\_speed value in the LIN description file.

The LIN synchronizer will perform the following functions: master header signal generation, slave detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

### 25.7.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time  $T_{bit}$ . The bit time is derived from the fields P and M in the baud rate selection register (BRS). There is an additional 3-bit fractional divider value, field U in the BRS register, which further fine tunes the data field baud rate.

The ranges for the prescaler values in the BRS are:

$$P = 0, 1, 2, 3, \dots, 2^{24} - 1$$

$$M = 0, 1, 2, \dots, 15$$

$$U = 0, 1, 2, 3, 4, 5, 6, 7$$

The P, M, and U values in the BRS are user programmable. The P and M dividers could be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that “**a** TVCLK” (with **a** = 0,1) is added to each  $T_{bit}$  as explained in [Section 25.7.4.2](#). If the ADAPT bit is set and the LIN slave is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as follows:

$$1\text{kHz} \leq F_{LINCLK} \leq 20\text{kHz}$$

All transmitted bits are shifted in and out at  $T_{bit}$  periods.

#### 25.7.4.1 Fractional Divider

The M field in the BRS modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time,  $T_{bit}$  is expressed in terms of the VCLK period  $T_{VCLK}$  as follows:

For all P other than 0, and all M,

$$T_{bit} = 16 \left( P + 1 + \frac{M}{16} \right) T_{VCLK} \quad (41)$$

For P = 0 :  $T_{bit} = 32 T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P + 1 + \frac{M}{16})} \quad \text{For all } P \text{ other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For } P = 0 \quad (42)$$

### 25.7.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN master mode (synch field + identifier field + response field + checksum field)
- LIN slave mode (response field + checksum field)

### 25.7.4.3 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRS[27:24], the super fractional divider uses an additional 3-bit modulating value, illustrated in [Table 25-7](#). The sync field (0x55), the identifier field and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table will have an additional VCLK period added to their  $T_{bit}$ .

**Table 25-7. Superfractional Bit Modulation for LIN Master Mode and Slave Mode<sup>(1)</sup>**

| BRS[30:28] | Start Bit | D[0] | D[1] | D[2] | D[3] | D[4] | D[5] | D[6] | D[7] | Stop Bit |
|------------|-----------|------|------|------|------|------|------|------|------|----------|
| 0h         | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0        |
| 1h         | 1         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    | 0        |
| 2h         | 1         | 0    | 0    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 3h         | 1         | 0    | 1    | 0    | 1    | 0    | 0    | 0    | 1    | 0        |
| 4h         | 1         | 0    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 0        |
| 5h         | 1         | 1    | 1    | 0    | 1    | 0    | 1    | 0    | 1    | 1        |
| 6h         | 1         | 1    | 1    | 0    | 1    | 1    | 1    | 0    | 1    | 1        |
| 7h         | 1         | 1    | 1    | 1    | 1    | 1    | 1    | 0    | 1    | 1        |

(1)

1. In LIN master mode, bit modulation applies to synch field + identifier field + response field
2. In LIN slave mode, bit modulation applies to identifier field + response field

The baud rate will vary over a LIN data field to average according to the BRS[30:28] value by a  $d$  fraction of the peripheral internal clock:  $0 < d < 1$ .

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (43)$$

For P = 0,  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK} \quad (44)$$

For P = 0,  $T_{bit} = 32T_{VCLK}$

With the superfractional divider, a LIN baud rate of 20 kbps is achievable with an internal clock VCLK of 726 kHz. Furthermore, a rate of 400 kbps is achievable with an VCLK of 14.6 MHz.

### 25.7.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA will trigger a message header generation and the LIN state machine will handle the generation itself. A master node initiates header generation on CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the master to initiate a LIN communication and consists of three fields: break field, synchronization field, and identification field, as seen in Figure 25-15.

**Figure 25-15. Message Header in Terms of  $T_{bit}$**

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The synch break length may be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The synch break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. It is used to convey  $T_{bit}$  information and resynchronize LIN bus nodes.
- The identifier field's ID byte may use six bits as an identifier, with optional length control (see *Note: Optional Control Length Bits*), and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITY ENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 25-16 for an illustration of the ID field.

**Figure 25-16. ID Field**

**NOTE: Optional Control Length Bits**

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

**NOTE:** If the BLIN module, configured as Slave in multi-buffer mode, is in the process of transmitting data while a new header comes in, the module might end up in responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario the following procedure could be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise TD0/TD1 might be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data will be transmitted by the node.

### 25.7.5.1 Event Triggered Frame Handling Proposal

The LIN 2.0 protocol uses event-triggered frames that may occasionally cause collisions. Event-triggered frames have to be handled in software.

If no slave answers to an event triggered frame header, the master node will set the NRE flag, and a NRE interrupt will occur if enabled. If a collision occurs, a frame error and checksum error may arise before the NRE error. Those errors are flagged and the appropriate interrupts will occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding slaves. If the slaves are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The bus busy flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision the flag is cleared in the same cycle as the NRE flag is set.

Software could implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the bus busy flag to get set or NRE flag to get set.
- If bus busy flag is not set before NRE flag, then it is a true no response case (no data has been transmitted onto the bus).
- If bus busy flag gets set, then wait for NRE flag to get set or for successful reception. If NRE flag is set, then in this case a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

### 25.7.5.2 Header Reception and Adaptive Baud Rate

A slave node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a slave measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the slave node's programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The LIN synchronizer determines two measurements: BRK\_count and BAUD\_count (Figure 25-17). These values are always calculated during the Header reception for synch field validation (Figure 25-18).

**Figure 25-17. Measurements for Synchronization**

By measuring the values BRK\_count and BAUD\_count, a valid synch break sequence can be detected as described in Figure 25-18. The four numbered events in Figure 25-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the synch break relative to the detecting node  $T_{bit}$ . For a slave node receiving the synch break, a threshold of  $11 T_{bit}$  is used as required by the LIN protocol. For detection of the dominant data stream of the synch break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the synch break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD\_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A slave node can calculate a single  $T_{bit}$  time by division of BAUD\_count by 8. In addition, for consistency between the detected edges the following is evaluated:

$$BAUD\_count + BAUD\_count \gg 2 + BAUD\_count \gg 3 \leq BRK\_count$$

The BAUD\_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a  $T_{bit}$  unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 25-18, if the measured BRK\_count value is less than  $11 T_{bit}$ , the synch break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK\_count and BAUD\_count values and automatically adjusts to any allowed LIN bus rate (refer to LIN Specification Package 2.0).

**NOTE:** In adaptive mode, the MBRS divider should be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a synch break.

The break-threshold relative to the slave node is  $11 T_{bit}$ . The break is  $13 T_{bit}$  as specified in LIN version 1.3.

**Figure 25-18. Synchronization Validation Process and Baud Rate Adjustment**

If the synch field is not detected within the given tolerances, the inconsistent-synch-field-error (ISFE) flag will be set. An ISFE interrupt will be generated, if enabled by its respective bit in the SCISSETINT register. The ID byte should be received after the synch field validation was successful. Any time a valid break (larger than  $11 T_{bit}$ ) is detected, the receiver's state machine should reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

---

**NOTE:** When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to their normal states

---

### 25.7.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier will be set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see [Figure 25-19](#). Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

**Figure 25-19. Optional Embedded Checksum in Response for Extended Frames**

An ID interrupt will be generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC will initiate an automatic send of the checksum byte. The last data field should always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see [Figure 25-20](#).

---

**NOTE:** The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

---

**Figure 25-20. Checksum Compare and Send for Extended Frames**

### 25.7.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a master node could flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

#### 25.7.7.1 No-Response Error (NRE)

The no-response error will occur when any node expecting a response waits for  $T_{\text{FRAME\_MAX}}$  time and the message frame is not fully completed within the maximum length allowed,  $T_{\text{FRAME\_MAX}}$ . After this time a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{\text{FRAME\_MIN}} = T_{\text{HEADER\_MIN}} + T_{\text{DATA\_FIELD}} + T_{\text{CHECKSUM\_FIELD}}$$

$$= 44 + 10N$$

where  $N$  = number of data fields.

And the maximum time frame is given by:

$$T_{\text{FRAME\_MAX}} = T_{\text{FRAME\_MIN}} * 1.4$$

$$= (44 + 10N) * 1.4$$

The timeout value  $T_{\text{FRAME\_MAX}}$  is derived from the  $N$  number of data fields value. The  $N$  value is either embedded in the header's ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register, will indicate the value for  $N$ .

**NOTE:** The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE will not be handled by the LIN controller hardware.

**Table 25-8. Timeout Values in  $T_{bit}$  Units**

| N | $T_{DATA\_FIELD}$ | $T_{FRAME\_MIN}$ | $T_{FRAME\_MAX}$ |
|---|-------------------|------------------|------------------|
| 1 | 10                | 54               | 76               |
| 2 | 20                | 64               | 90               |
| 3 | 30                | 74               | 104              |
| 4 | 40                | 84               | 118              |
| 5 | 50                | 94               | 132              |
| 6 | 60                | 104              | 146              |
| 7 | 70                | 114              | 160              |
| 8 | 80                | 124              | 174              |

### 25.7.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 s (this is 80,000  $F_{LINCLK}$  cycles with the fastest bus rate of 20 kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, then it can be assumed that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

---

**NOTE:** After the timeout was flagged, a software RESET should be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame was on the bus before the idle period.

---

### 25.7.7.3 Timeout after Wakeup Signal and Timeout after Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup should expect a header from the master within a defined amount of time: timeout after wakeup signal. See [Section 25.11.3](#) for more details.

### 25.7.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

### 25.7.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor ensures that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 25-21.

**NOTE:** If BE Occurs due to New Header reception during a Slave Response, NRE/TIMEOUT flag will not be set for the new Frame.

Figure 25-21. TXRX Error Detector

### 25.7.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a master if no valid message can be generated on the bus (Bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break Delimiter can be generated (for example, because of a bus shortage to GND). Once the Synch Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

### 25.7.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm.

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \text{ (even Parity)}$$

$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \text{ (odd Parity)} \quad (45)$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 25.7.9 for details.

#### 25.7.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end if the calculated modulo-256 sum over all received data bytes (including the ID byte if it is the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of its resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see [Figure 25-22](#)) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see [Figure 25-23](#)) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation should always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit will be overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

**Figure 25-22. Classic Checksum Generation at Transmitting Node**

**Figure 25-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node**

### 25.7.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes will participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used, as shown in [Figure 25-24](#). During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in [Figure 25-16](#)) to determine whether they transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See [Figure 25-24](#). All nodes compare the received ID to the identifier stored in the ID-SlaveTask BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there will be an ID TX flag and an interrupt will be triggered if enabled in the SCISSETINT register.

The masked bits become don't cares for the comparison. To build a mask for a set of identifiers, an XOR function could be used.

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most significant bits (MSBs) and filter 3 least significant bits (LSBs), the acceptance mask could be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07 \quad (46)$$

A mask of all zeros will compare all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF will always cause a match. A mask of all 1s will filter all bits of the received identifier, and thus there will be an ID match regardless of the content of the ID-SlaveTask BYTE field in the LINID register.

---

**NOTE:** When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that should not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there will be an ID RX flag and an interrupt will be triggered if enabled. A mask of all 0s will compare all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s will filter all bits of the received identifier and there will be no match.

---

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU may read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

---

**NOTE:** When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

---

In multi-buffer mode, the TXRDY flag will be set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multi-buffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multi-buffer mode, the TXEMPTY flag is set when both the transmit buffer(s) TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In non multi-buffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all slave receiving nodes will validate the identifier using all eight bits of the received ID byte. The SCI/LIN will flag a corrupted identifier if an ID-parity error is detected.

**Figure 25-24. ID Reception, Filtering and Validation**

### 25.7.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt will be generated if enabled in the SCISSETINT register.

The multi-buffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multi-buffer mode is enabled, or to RD0 if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the ID BYTE field does not convey message length (see *Note: Optional Control Length Bits* in [Section 25.7.5](#)), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

[Figure 25-8](#) illustrates the receive buffers.

A receive interrupt, and a receive ready RXRDY flag set as well as a DMA request (RXDMA) could occur after receiving a response if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte will be compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multi-buffer mode is enabled or not (MBUF MODE bit in the SCIGCR1 register).

---

**NOTE:** In multi-buffer mode, following are the scenarios associated with clearing the RXRDY flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
  2. For LENGTH less than or equal to 4, Read to RD0 register will clear the RXRDY flag.
  3. For LENGTH greater than 4, Read to RD1 register will clear the RXRDY flag.
-

### 25.7.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TXy transmit buffers. Optionally, a DMA transfer could be done on a byte-per-byte basis when multi-buffer mode is not enabled (MBUF MODE bit in the SCIGCR1 register).

The multi-buffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multi-buffer mode is enabled, or from TD0 to SCITXSHF if multi-buffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in [Section 25.7.5](#)), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMM MODE bit.

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag), and a DMA request (TXDMA) could occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multi-buffer mode is enabled or not (MBUF MODE bit in the SCIGCR1 register).

[Figure 25-9](#) illustrates the transmit buffers.

The checksum byte will be automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multi-buffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

---

**NOTE:** The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLRINT register or by disabling the transmitter via the TXENA bit.

---

## 25.8 LIN Interrupts

LIN and SCI mode have a common Interrupt block as explained in [Section 25.3](#). There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in [Table 25-4](#).

A LIN message frame indicating the timing and sequence of the LIN interrupts that could occur is shown in [Figure 25-25](#).

**Figure 25-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence**

## 25.9 LIN DMA Interface

LIN DMA Interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multi-buffer mode is enabled or not via the multi-buffer enable control bit (MBUF MODE bit in the SCIGCR1 register).

### 25.9.1 LIN Receive DMA Requests

In LIN mode, when the multi-buffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled/disabled by the user using SET RX DMA / CLR RX DMA bits, respectively.

### 25.9.2 LIN Transmit DMA Requests

In LIN mode with the multi-buffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffer(s) TDy in the LINTD0 and LINTD1 registers), a DMA request is generated in order to reload the transmit buffer for the next transmission. If the multi-buffer option is disabled, then DMA requests will be generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled/disabled by the user using SET TX DMA / CLR TX DMA bits, respectively.

## 25.10 LIN Configurations

The following list details the configuration steps that software should perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting the RESET bit in SCIGCR0 to 1.
- Clear the SWnRST bit to 0 before LIN is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for LIN functionality.
- Set the LIN MODE bit in SCIGCR1 to 1 to enable LIN mode.
- Select Master or Slave mode by programming the CLOCK bit in SCIGCR1.
- Set the MBUF MODE bit in SCIGCR1 to 1 to select multi-buffer mode.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the maximum baud rate to be used for communication by programming the MBRS register.
- Set the CONT bit in SCIGCR1 to 1 to make LIN not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Select the RX ID MASK and the TX ID MASK fields in the LINMASK register.
- Set the SWnRST bit to 1 after LIN is configured.
- Perform receiving or transmitting data (see [Section 25.10.1](#) or [Section 25.10.2](#)).

### 25.10.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The ID RX FLAG is set after a valid LIN ID is received with RX Match. An ID interrupt is generated, if enabled.

#### 25.10.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when it transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum will be compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit will be cleared once the checksum is received. A CE will immediately be flagged if there is a checksum error.

### 25.10.1.2 Receiving Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that it monitors for the complete frame. Like single-buffer mode, you can use the polling, interrupt, or DMA method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit will be cleared once the checksum is received and compared.

### 25.10.2 Transmitting Data

The LIN transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The ID TX flag is set after a valid LIN ID is received with TX Match. An ID interrupt is generated, if enabled.

#### 25.10.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUF MODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte will be sent after the current byte transmission. The SC bit will be cleared after the checksum byte has been transmitted.

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

### 25.10.2.2 Transmitting Data in Multi-Buffer Mode

Multi-buffer mode is selected when the MBUF MODE bit is set to 1. Like single-buffer mode, you can use the polling, interrupt, or DMA method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum will be sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit will be cleared after the checksum byte has been transmitted.

## 25.11 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The BLIN module may enter low-power mode either when there was no activity on the LINRX pin for more than 4s (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal will terminate the sleep mode of the LIN bus.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wake-up interrupt to clear the powerdown bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

---

### 25.11.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic master request frame with identifier 0x3C (60), with the first data field as 0x00. There should be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

### 25.11.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

**NOTE:** If the wakeup interrupt is disabled then the SCI/LIN enters low-power mode whenever it is requested to do so, but a low level on the receive RX pin does NOT cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal; see Figure 25-26. A slave node that detects the bus in sleep mode, and with a wakeup request pending, will send a wakeup signal. The wakeup signal is a dominant value on the LIN bus for  $T_{WUSIG}$ ; this is at least  $5 T_{bits}$  for the LIN bus baud rates. The wakeup signal is generated by sending an 0xF0 byte containing 5 dominant  $T_{bits}$  and 5 recessive  $T_{bits}$ .

**Figure 25-26. Wakeup Signal Generation**

$$0.25\text{ms} \leq T_{WUSIG} \leq 5\text{ms}$$

(47)

Assuming a perfect bus with no noise or loading effects, a write of 0xF0 to TD0 will load the transmitter to meet the wakeup signal timing requirement for  $T_{WUSIG}$ . Then, setting the GENWU bit will transmit the preloaded value in TD0 for a wakeup signal transmission.

**NOTE:** The GENWU bit can be set/reset only when SWnRST is set to '1' and the node is in power down mode. The bit will be cleared on a valid synch break detection. A master sending a wakeup request, will exit power down mode upon reception of the wakeup pulse. The bit will be cleared on a SWnRST. This can be used to stop a master from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, will translate it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, it will generate a wakeup interrupt if enabled in the SCISSETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150 ms will detect it as a wakeup request. The LIN controller's slave is ready to listen to the bus in less than 100 ms ( $T_{INITIALIZE} < 100\text{ms}$ ) after a dominant-to-recessive edge (end-of-wakeup signal).

### 25.11.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the master to send a header. If no synch field is detected before 150 ms (3,000 cycles at 20 kHz) after wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5 s (30,000 cycles at 20 kHz) period after three breaks.

---

**NOTE:** To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to assure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup should set the MBRS register accordingly to meet the targeted time as  $128 \text{ Tbits} \times \text{programmed prescaler}$ .

The LIN controller handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

---

### 25.12 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. When set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register will not have any effect on the flags in the SCIFLR register.

---

**NOTE:** When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

---

## 25.13 SCI/LIN Control Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in [Table 25-9](#). Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration. The base address for the control registers is FFF7 E400h.

**Table 25-9. SCI/LIN Control Registers**

| Offset | Acronym       | Register Description                 | Section                            |

### 25.13.1 SCI Global Control Register 0 (SCIGCR0)

The SCIGCR0 register defines the module reset. [Figure 25-27](#) and [Table 25-10](#) illustrate this register.

**Figure 25-27. SCI Global Control Register 0 (SCIGCR0) [offset = 00]**

LEGEND: R/W = Read/Write; R = Read only; R/WP = Read/Write in privileged mode only; -n = value after reset

**Table 25-10. SCI Global Control Register 0 (SCIGCR0) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                          |

| 31-1 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                               |
| 0    | RESET    | 0<br>1 | This bit resets the SCI/LIN module. This bit is effective in SCI and LIN mode.<br>SCI/LIN module is in reset.<br>SCI/LIN module is out of reset.<br><b>Note: Read/Write in privileged mode only.</b> |

### 25.13.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. Figure 25-28 and Table 25-11 illustrate this register.

**Figure 25-28. SCI Global Control Register 1 (SCIGCR1) [offset = 04h]**

Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 25-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit   | Field          | Value             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17    | CONT           | <p>0</p> <p>1</p> | <p>Continue on suspend. This bit is effective in LIN and SCI modes. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit: when the bit is set the counters are not stopped, when the bit is cleared the counters are stopped during debug mode.</p> <p>When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited.</p> <p>When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.</p>                                                                                                                                   |
| 16    | LOOP BACK      | <p>0</p> <p>1</p> | <p>Loopback bit. This bit is effective in LIN and SCI modes. The self-checking option for the SCI/LIN can be selected with this bit. If the LINITX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result.</p> <p>Loop back mode is disabled.</p> <p>Loop back mode is enabled.</p>                                                                                                                                                                                                                                                 |
| 15-14 | Reserved       | 0                 | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 13    | STOP EXT FRAME | <p>0</p> <p>1</p> | <p>Stop extended frame communication. This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically.</p> <p>This bit has no effect.</p> <p>Extended frame communication will be stopped when current frame transmission/reception is completed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 12    | HGEN CTRL      | <p>0</p> <p>1</p> | <p>HGEN control. This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison</p> <p>ID filtering using the ID-BYTE field in LIN Identification Register (LINID) occurs.</p> <p>Mask of FFh in LIN Mask Register (LINMASK) register will result in no match.</p> <p>ID filtering uses ID-SlaveTask BYTE (recommended).</p> <p>Mask of FFh in LIN Mask Register (LINMASK) register will result in ALWAYS match.</p> <p><b>Note: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK must be set to FFh, and the TX ID MASK must be set to FFh.</b></p>                                                                                                                                                                                        |
| 11    | CTYPE          | <p>0</p> <p>1</p> | <p>Checksum type. This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.</p> <p>Classic checksum is used.</p> <p>Enhanced checksum is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 10    | MBUF MODE      | <p>0</p> <p>1</p> | <p>Multi-buffer mode. This bit is effective in LIN and SCI modes. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multi-buffers are used or a single register, RD0/TD0, is used.</p> <p>Multi-buffer mode is disabled.</p> <p>Multi-buffer mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 9     | ADAPT          | <p>0</p> <p>1</p> | <p>Adapt. This mode is effective in LIN mode only. This bit has an effect during the detection of the synch field. Two LIN protocol bit rate modes could be enabled with this bit according to the node capability file definition: automatic or select. The software and network configuration will decide which of these two modes are enabled. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a SCI/LIN slave node detecting the baud rate will compare it to the prescalers in BRS register and update it if they are different. The BRS register will be updated with the new value. If this bit is not set there will be no adjustment to the BRS register.</p> <p>Automatic baud rate adjustment is disabled.</p> <p>Automatic baud rate adjustment is enabled.</p> |

**Table 25-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit | Field    | Value                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|----------|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | SLEEP    | <div><div>0</div><div>1</div></div>                                     | <p>SCI sleep. This bit is effective in SCI mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI/LIN out of sleep mode.</p> <p>Sleep mode is disabled.</p> <p>Sleep mode is enabled.</p> <p><b>Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 25-12 ) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.</b></p> <p><b>Note: The SLEEP bit is <i>not</i> automatically cleared when an address byte is detected.</b></p> <p>See <a href="#">Section 25.6.1</a> for more information on using the SLEEP bit for multiprocessor communication.</p> |
| 7   | SWnRST   | <div><div>0</div><div>1</div></div>                                     | <p>Software reset (active low). This bit is effective in LIN and SCI modes.</p> <p>The SCI/LIN is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags as defined in <a href="#">Table 25-12</a> and <a href="#">Table 25-13</a>. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>The SCI/LIN is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.</p> <p><b>Note: The SCI/LIN should only be configured while SWnRST = 0.</b></p>                                                                                                                                                                                                                                                                                                                                                                 |
| 6   | LIN MODE | <div><div>0</div><div>1</div></div>                                     | <p>LIN mode. This bit is effective in LIN and SCI mode. This bit controls the module mode of operation.</p> <p>LIN mode is disabled; SCI mode is enabled.</p> <p>LIN mode is enabled; SCI mode is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 5   | CLOCK    | <div><div>0</div><div>1</div></div> <div><div>0</div><div>1</div></div> | <p>SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin. It also determines whether a LIN node is a slave or master.</p> <p><i>SCI mode</i></p> <p>The external SCICLK is the clock source.</p> <p><b>Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.</b></p> <p>The internal SCICLK is the clock source.</p> <p><i>LIN mode</i></p> <p>The node is in slave mode.</p> <p>The node is in master mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4   | STOP     | <div><div>0</div><div>1</div></div>                                     | <p>SCI number of stop bits per frame. This bit is effective in SCI mode only.</p> <p>One stop bit is used.</p> <p>Two stop bits are used.</p> <p><b>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3   | PARITY   | <div><div>0</div><div>1</div></div>                                     | <p>SCI parity odd/even selection. This bit is effective in SCI mode only. If the PARITY ENA bit is set, PARITY designates odd or even parity.</p> <p>Odd parity is used.</p> <p>Even parity is used.</p> <p><b>The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</b></p> <p><b>For odd parity, the SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</b></p> <p><b>For even parity, the SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</b></p>                                                                                                                                                                                                                                                |

**Table 25-11. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit | Field       | Value | Description                                                                                                                                                              |
|-----|-------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | PARITY ENA  |       | Parity enable. This bit enables or disables the parity function.                                                                                                         |
|     |             |       | <i>SCI or buffered SCI mode:</i>                                                                                                                                         |
|     |             | 0     | Parity is disabled; no parity bit is generated during transmission or is expected during reception.                                                                      |
|     |             | 1     | Parity is enabled. A parity bit is generated during transmission and is expected during reception.                                                                       |
| 1   | TIMING MODE |       | <i>LIN mode:</i>                                                                                                                                                         |
|     |             | 0     | ID field parity verification is disabled.                                                                                                                                |
|     |             | 1     | ID field parity verification is enabled.                                                                                                                                 |
|     |             |       | SCI timing mode bit. This bit is effective in SCI mode only. it selects the SCI timing mode.                                                                             |
| 0   | COMM MODE   |       |                                                                                                                                                                          |
|     |             | 0     | Synchronous timing is used.                                                                                                                                              |
|     |             | 1     | Asynchronous timing is used.                                                                                                                                             |
|     |             |       | SCI/LIN communication mode bit. In compatibility mode it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5. |
|     |             |       | <i>SCI mode:</i>                                                                                                                                                         |
|     |             | 0     | Idle-line mode is used.                                                                                                                                                  |
|     |             | 1     | Address-bit mode is used.                                                                                                                                                |
|     |             |       | <i>LIN mode:</i>                                                                                                                                                         |
|     |             | 0     | ID4 and ID5 are not used for length control.                                                                                                                             |
|     |             | 1     | ID4 and ID5 are used for length control.                                                                                                                                 |

**Table 25-12. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| CE       | SCIFLR   | 29  | 0                                |
| ISFE     | SCIFLR   | 28  | 0                                |
| NRE      | SCIFLR   | 27  | 0                                |
| FE       | SCIFLR   | 26  | 0                                |
| OE       | SCIFLR   | 25  | 0                                |
| PE       | SCIFLR   | 24  | 0                                |
| RXWAKE   | SCIFLR   | 12  | 0                                |
| RXRDY    | SCIFLR   | 9   | 0                                |

| IDLE     | SCIFLR   | 2   | 0                                |
| WAKE UP  | SCIFLR   | 1   | 0                                |
| BRKDT    | SCIFLR   | 0   | 0                                |

<sup>(1)</sup> The flags are frozen with their reset value while SWnRST = 0.

**Table 25-13. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After Reset <sup>(1)</sup> |
|----------|----------|-----|----------------------------------|
| BE       | SCIFLR   | 31  | 0                                |
| PBE      | SCIFLR   | 30  | 0                                |
| TX WAKE  | SCIFLR   | 10  | 0                                |
| TX EMPTY | SCIFLR   | 11  | 1                                |
| TXRDY    | SCIFLR   | 8   | 1                                |

<sup>(1)</sup> The flags are frozen with their reset value while SWnRST = 0.

### 25.13.3 SCI Global Control Register 2 (SCIGCR2)

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module. [Figure 25-29](#) and [Table 25-14](#) illustrate this register.

**Figure 25-29. SCI Global Control Register 2 (SCIGCR2) [offset = 08h]**

| 31-18 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 17    | CC       | 0<br>1 | Compare checksum. This bit is effective in LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit. CC bit has to be set only after RX_RDY flag is set for the last received data.<br><br>In non-multi-buffer mode, when the CC bit is set, the checksum will be compared on the byte that is expected to be the checksum byte.<br><br>During multi-buffer mode, the following scenarios are associated with the CC bit:<br>a) If the CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes as indicated by SCIFORMAT[18:16] is treated as a checksum byte.<br>b) If the CC bit is set during the idle period (that is, during the inter-frame space), then the immediate next byte will be treated as a checksum byte.<br>c) CC bit will be auto cleared after the checkbyte has been received and compared. Checksum reception is not guaranteed if CC bit is write cleared by software during the checksum reception. See <a href="#">Section 25.7.6</a> for more details. |
| 16    | SC       | 0<br>1 | Send checksum byte. This bit is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checksum byte. In non-multi-buffer mode, the checksum byte will be sent after the current byte transmission. In multi-buffer mode, the checksum byte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). See <a href="#">Section 25.7.6</a> for more details. This byte will be cleared after the checksum byte has been transmitted.<br><br>In non-multi-buffer mode, the checksum byte will be sent after the current byte transmission.<br><br>During multi-buffer mode, the following scenarios are associated with the SC bit:<br>a) The checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]).<br>b) Checksum will not be sent if SC is set before transmitting the very first byte(that is, during interframe space).<br>c) SC bit will be auto cleared after the checkbyte has been transmitted. Checksum transmission is not guaranteed if SC bit is write cleared by software during the checksum transmission. See <a href="#">Section 25.7.6</a> for more details.              |

| 8     | GEN WU   | 0<br>1 | Generate wakeup signal. This bit is effective in LIN mode only. This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. The LIN protocol specifies that this signal should be a dominant for T <sub>WUSIG</sub> . This bit is cleared on reception of a valid synch break.<br><br>0 No wakeup signal will be generated.<br>1 The TDO buffer value will be transmitted for a wakeup signal. The bit will be cleared on a SWnRST.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 7-1   | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 25-14. SCI Global Control Register 2 (SCIGCR2) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | POWERDOWN |       | Power down. This bit is effective in LIN or SCI mode. When this bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay entering low-power mode until the reception is completed. In LIN mode, the user may set the POWERDOWN bit after receiving a sleep command or on idle bus detection (more than 4 seconds). See <a href="#">Section 25.11</a> for more information on low-power mode. |
|     |           | 0     | The SCI/LIN module is in normal operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |           | 1     | The SCI/LIN module enters local low-power mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 25.13.4 SCI Set Interrupt Register (SCISSETINT)

Figure 25-30 and Table 25-15 illustrate this register. Refer Figure 25-30 for details on when different interrupt flags get set in a frame during LIN Mode.

**Figure 25-30. SCI Set Interrupt Register (SCISSETINT) [offset = 0Ch]**

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; -n = value after reset

**Table 25-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions**

| Bit | Field        | Value | Description                                                                                                                                                                                                                                                                                                    |
|-----|--------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | SET BE INT   | 0     | Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                            |
|     |              | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                |
| 30  | SET PBE INT  | 0     | Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                            |
|     |              | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                |
| 29  | SET CE INT   | 0     | Set checksum-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                  |
|     |              | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                |
| 28  | SET ISFE INT | 0     | Set inconsistent-synch-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent synch field error.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |              | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                |
| 27  | SET NRE INT  | 0     | Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                              |
|     |              | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                |

**Table 25-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | SET FE INT     | 0     | Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                              |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 25    | SET OE INT     | 0     | Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                             |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 9     | SET RX INT     | 0     | Receiver interrupt enable. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                        |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 25-15. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit | Field           | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|-----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | SET TX INT      | 0     | Set transmitter interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                             |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 7   | SET TOA3WUS INT | 0     | Set timeout after three wakeup signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after three wakeup signals have been sent.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                              |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 6   | SET TOAWUS INT  | 0     | Set timeout after wakeup signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when a timeout occurs after one wakeup signal has been sent.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                         |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 5   | Reserved        | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4   | SET TIMEOUT INT | 0     | Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is no LIN bus activity (bus idle) for at least four seconds.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                  |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 3-2 | Reserved        | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 1   | SET WAKEUP INT  | 0     | Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the LINRX pin during low-power mode.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0   | SET BRKDT INT   | 0     | Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an error interrupt if a break condition is detected on the LINRX pin.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                 |
|     |                 | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 25.13.5 SCI Clear Interrupt Register (SCICLEARINT)

Figure 25-31 and Table 25-16 illustrate this register. SCICLEARINT register is used to clear the enabled interrupts without accessing SCISSETINT register.

**Figure 25-31. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]**

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; WC = Write in SCI-compatible mode only; -n = value after reset

**Table 25-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions**

| Bit | Field        | Value | Description                                                                                                                                                                                                                                      |
|-----|--------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | CLR BE INT   | 0     | Clear bit error interrupt. This bit is effective in LIN mode only. This bit disables the bit error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                        |
|     |              | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                               |
| 30  | CLR PBE INT  | 0     | Clear physical bus error interrupt. This bit is effective in LIN mode only. This bit disables the physical-bus error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.      |
|     |              | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                               |
| 29  | CLR CE INT   | 0     | Clear checksum-error interrupt. This bit is effective in LIN mode only. This bit disables the checksum interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                    |
|     |              | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                               |
| 28  | CLR ISFE INT | 0     | Clear inconsistent-synch-field-error (ISFE) interrupt. This bit is effective in LIN mode only. This bit disables the ISFE interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |              | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                               |

**Table 25-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27    | CLR NRE INT    | 0     | Clear no-response-error interrupt. This bit is effective in LIN mode only. This bit disables the NRE interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                             |
|       |                | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                                                                                      |
| 26    | CLR FE INT     | 0     | Clear framing-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the framing-error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                     |
|       |                | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                                                                                      |
| 25    | CLR OE INT     | 0     | Clear overrun-error interrupt. This bit is effective in LIN or SCI mode. This bit disables the SCI/LIN overrun error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                             |
|       |                | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                                                                                      |
| 24    | CLR PE INT     | 0     | Clear parity interrupt. This bit is effective in LIN or SCI mode. This bit disables the parity error interrupt when set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                             |
|       |                | 1     | <i>Read:</i> The interrupt is enabled.<br><i>Write:</i> The interrupt is disabled.                                                                                                                                                                                                                                                                                                                                                      |
| 23-19 | Reserved       | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18    | CLR RX DMA ALL | 0     | Clear receive DMA all. This bit is effective in SCI mode only. This bit clears the receive DMA request for address frames when set. Only receive data frames generate a DMA request.<br><i>Read:</i> Receive DMA request for address frames is disabled; Instead, RX interrupt requests are enabled for address frames. Receive DMA requests are still enabled for data frames.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|       |                | 1     | <i>Read:</i> Receive DMA request for address and data frames is enabled.<br><i>Write:</i> Receive DMA request for address and data frames is disabled.                                                                                                                                                                                                                                                                                  |
| 17    | CLR RX DMA     | 0     | Clear receive DMA request. This bit is effective in LIN or SCI mode. This bit disables the receive DMA request when set.<br><i>Read:</i> Receive DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                       |
|       |                | 1     | <i>Read:</i> Receive DMA request is enabled.<br><i>Write:</i> Receive DMA request for is disabled.                                                                                                                                                                                                                                                                                                                                      |
| 16    | CLR TX DMA     | 0     | Clear transmit DMA request. This bit is effective in LIN or SCI mode. This bit disables the transmit DMA request when set.<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                    |
|       |                | 1     | <i>Read:</i> Transmit DMA request is enabled.<br><i>Write:</i> Transmit DMA request for is disabled.                                                                                                                                                                                                                                                                                                                                    |
| 15-14 | Reserved       | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 25-16. SCI Clear Interrupt Register (SCICLEARINT) Field Descriptions (continued)**

| Bit   | Field           | Value | Description                                                                                                                                                                                                                                                                 |
|-------|-----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Table 25-18. SCI Clear Interrupt Level Register (SCICLEARINTLVL) Field Descriptions**

| Bit | Field            | Value | Description                                                                                                                                                                                                            |
|-----|------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | CLR BE INT LVL   | 0     | Clear bit error interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                             |
|     |                  | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                          |
| 30  | CLR PBE INT LVL  | 0     | Clear physical bus error interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                    |
|     |                  | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                          |
| 29  | CLR CE INT LVL   | 0     | Clear checksum-error interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                        |
|     |                  | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                          |
| 28  | CLR ISFE INT LVL | 0     | Clear inconsistent-synch-field-error (ISFE) interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |                  | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                          |
| 27  | CLR NRE INT LVL  | 0     | Clear no-response-error interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                     |
|     |                  | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                          |

**Table 25-18. SCI Clear Interrupt Level Register (SCICLEARINTLVL) Field Descriptions (continued)**

| Bit   | Field               | Value | Description                                                                                                                                                                                                                                |
|-------|---------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | CLR FE INT LVL      | 0     | Clear framing-error interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 25    | CLR OE INT LVL      | 0     | Clear overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 24    | CLR PE INT LVL      | 0     | Clear parity interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                       |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 23-19 | Reserved            | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                     |
| 18    | CLR RX DMA ALL LVL  | 0     | Clear receive DMA interrupt level. This bit is effective in SCI-compatible mode only.<br><i>Read:</i> The receive interrupt request for address frames is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|       |                     | 1     | <i>Read:</i> The receive interrupt request for address frames is mapped to the INT1 line.<br><i>Write:</i> The receive interrupt request for address frames is mapped to the INT0 line.                                                    |
| 17-14 | Reserved            | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                     |
| 13    | CLR ID INT LVL      | 0     | Clear ID interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                        |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 12-10 | Reserved            | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                     |
| 9     | CLR RX INT LVL      | 0     | Clear receiver interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                     |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 8     | CLR TX INT LVL      | 0     | Clear transmitter interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                  |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |
| 7     | CLR TOA3WUS INT LVL | 0     | Clear timeout after three wakeup signals interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                        |
|       |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                                              |

**Table 25-18. SCI Clear Interrupt Level Register (SCICLEARINTLVL) Field Descriptions (continued)**

| Bit | Field               | Value | Description                                                                                                                                                                                                  |
|-----|---------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6   | CLR TOAWUS INT LVL  | 0     | Clear timeout after wakeup signal interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                |
| 5   | Reserved            | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                       |
| 4   | CLR TIMEOUT INT LVL | 0     | Clear timeout interrupt. This bit is effective in LIN mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.                     |
|     |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                |
| 3-2 | Reserved            | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                       |
| 1   | CLR WAKEUP INT LVL  | 0     | Clear wake-up interrupt. This bit is effective in LIN or SCI-compatible mode.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.        |
|     |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                |
| 0   | CLR BRKDT INT LVL   | 0     | Clear break-detect interrupt. This bit is effective in SCI-compatible mode only.<br><i>Read:</i> The interrupt level is mapped to the INT0 line.<br><i>Write:</i> Writing a 0 to this bit has no effect.     |
|     |                     | 1     | <i>Read:</i> The interrupt level is mapped to the INT1 line.<br><i>Write:</i> The interrupt level is mapped to the INT0 line.                                                                                |

### 25.13.8 SCI Flags Register (SCIFLR)

Figure 25-34 and Table 25-19 illustrate this register.

| 31  | BE    |       | Bit error flag. This bit is effective in LIN mode only. This bit is set when a bit error has occurred. This is detected by the internal bit monitor. See <a href="#">Section 25.7.8</a> for more information. The bit error flag is cleared by any of the following:                                                                                                                                                                                                                                                                                                                                                                         |
|     |       | 0     | <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>On reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> Read: No error has been detected since this bit was last cleared.<br>Write: Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                    |
|     |       | 1     | Read: An error has been detected since this bit was last cleared.<br>Write: The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30  | PBE   |       | Physical bus error flag. This bit is effective in LIN mode only. This bit is set when a physical bus error has been detected by the bit monitor in TED. See <a href="#">Section 25.7.8</a> for more information. The physical bus error flag is cleared by the following:                                                                                                                                                                                                                                                                                                                                                                    |
|     |       | 0     | <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>On reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <b>Note: The PBE will only be flagged, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break Delimiter can be generated (for example, because of a bus shortage to GND).</b><br>Read: No error has been detected since this bit was last cleared.<br>Write: Writing a 0 to this bit has no effect. |
|     |       | 1     | Read: An error has been detected since this bit was last cleared.<br>Write: The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 25-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 29  | CE    |       | Checksum error flag. This bit is effective in LIN mode only. This bit is set when a checksum error has been detected by a receiving node. This error is detected by the TED logic. See <a href="#">Section 25.7.8</a> for more information. The type of checksum to be used depends on the CTYPE bit in SCIGCR1. The checksum error flag is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul>                                             |
|     |       | 0     | <i>Read:</i> No error has been detected since this bit was last cleared.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|     |       | 1     | <i>Read:</i> An error has been detected since this bit was last cleared.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 28  | ISFE  |       | Inconsistent synch field error flag. This bit is effective in LIN mode only. This bit is set when an inconsistent synch field error has been detected by the synchronizer during header reception. See <a href="#">Section 25.7.5.2</a> for more information. The inconsistent synch field error flag is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul>                                                                                |
|     |       | 0     | <i>Read:</i> No inconsistent synch field error has been detected.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|     |       | 1     | <i>Read:</i> An inconsistent synch field error has been detected.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 27  | NRE   |       | No-response error flag. This bit is effective in LIN mode only. This bit is set when there is no response to a master's header completed within TFRAME_MAX. This timeout period is applied for message frames of known length (identifiers 0 to 61). This error is detected by the synchronizer. See <a href="#">Section 25.7.7</a> for more information. The no-response error flag is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |
|     |       | 0     | <i>Read:</i> No no-response error has been detected since the last clear.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|     |       | 1     | <i>Read:</i> A no-response error has been detected.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 25-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | FE       |       | <p>Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI/LIN to generate an error interrupt if the SET FE INT bit is set in the register SCISSETINT. The framing error flag is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> <li>Reception of a new character/frame, depending on whether the module is in SCI compatible or LIN mode</li> </ul> <p>In multi-buffer mode, the frame is defined in the SCIFORMAT register.</p>                                                                                     |
|       |          | 0     | <p><i>Read:</i> No framing error has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|       |          | 1     | <p><i>Read:</i> A framing error has been detected since the last clear.<br/><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 25    | OE       |       | <p>Overrun error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers in LINRD0 and LINRD1. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit = 1. The OE flag is reset by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|       |          | 0     | <p><i>Read:</i> No overrun error has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|       |          | 1     | <p><i>Read:</i> An overrun error has been detected.<br/><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 24    | PE       |       | <p>Parity error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. The PE bit is reset by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reception of a new character or frame, depending on whether the module is in SCI compatible or LIN mode, respectively.</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |
|       |          | 0     | <p><i>Read:</i> No parity error has been detected since the last clear.<br/><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 14  | ID RX FLAG |       | Identifier on receive flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with an receive match and no ID-parity error. See <a href="#">Section 25.7.9</a> for more details. This flag indicates that a new valid identifier has been received on an RX match. This bit is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the LINID register</li> <li>Reception of a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |
|     |            | 0     | <i>Read:</i> No valid ID has been received since the last clear.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|     |            | 1     | <i>Read:</i> A valid ID RX has been received in LINID[23:16] on an RX match.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 13  | ID TX FLAG |       | Identifier on transmit flag. This bit is effective in LIN mode only. This flag is set when an identifier is received with a transmit match and no ID-parity error. See <a href="#">Section 25.7.9</a> for more details. This flag indicates that a new valid identifier has been received on a TX match. This bit is cleared by the following: <ul style="list-style-type: none"> <li>Setting the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the LINID register</li> <li>Receiving a new synch break</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul>       |
|     |            | 0     | <i>Read:</i> No valid ID has been received since the last clear.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|     |            | 1     | <i>Read:</i> A valid ID TX has been received in LINID[23:16] on an TX match.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 12  | RXWAKE     |       | Receiver wakeup detect flag. This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. RXWAKE is cleared by the following: <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Upon receipt of a data frame.</li> </ul>                                                                                                                                                                                                                                                                                     |
|     |            | 0     | The data in SCIRD is not an address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|     |            | 1     | The data in SCIRD is an address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 11  | TX EMPTY   |       | Transmitter empty flag. This flag indicates the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF) are empty. In multi-buffer mode, this flag indicates the TDx registers and shift register (SCITXSHF) are empty. In non-multi-buffer mode, this flag indicates the LINTD0 byte and the shift register (SCITXSHF) are empty.<br><br><b>Note: The RESET bit, an active SWnRST (SCIGCR1[7]) or a system reset sets this bit. This bit does not cause an interrupt request.</b><br><i>SCI mode or LIN non-multi-buffer mode:</i>                                                                                                                 |
|     |            | 0     | Transmitter buffer or shift register (or both) are loaded with data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|     |            | 1     | Transmitter buffer and shift registers are both empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|     |            |       | <i>In LIN mode using multi-buffer mode:</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|     |            | 0     | Multi-buffer or shift register (or all) are loaded with data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|     |            | 1     | Multi-buffer and shift registers are all empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 25-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 10  | TXWAKE |       | Transmitter wakeup method select. This bit is effective in SCI mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset.<br><b>Note: TXWAKE is not cleared by the SWnRST bit.</b><br><i>Address-bit mode:</i><br>0 Frame to be transmitted will be data (address bit = 0).<br>1 Frame to be transmitted will be an address (address bit = 1).<br><i>Idle-line mode:</i><br>0 The frame to be transmitted will be data.<br>1 The following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 9   | RXRDY  |       | Receiver ready flag. In SCI-compatible mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In <i>LIN mode</i> , RXRDY is set once a valid frame is received in multi-buffer mode, a valid frame being a message frame received with no errors. In <i>non-multi-buffer mode</i> , RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit is set (SCISSETINT[9]); RXRDY is cleared by the following:<br><ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the SCIRD register in compatibility mode</li> <li>Reading the last data byte RDy of the response in LIN mode</li> </ul> <b>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b><br>0 <i>Read:</i> No new data is in SCIRD.<br><i>Write:</i> Writing a 0 to this bit has no effect.<br>1 <i>Read:</i> New data is ready to be read from SCIRD.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                    |
| 8   | TXRDY  |       | Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer(s) register(s) (SCITD in compatibility mode and LINTD0/LINTD1 in multi-buffer mode) are ready to get another character from a CPU write.<br><i>In SCI</i> , writing data to SCITD automatically clears this bit. <i>In LIN mode</i> , this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the SET TX INT bit is set.<br><b>Note:</b><br>1) TXRDY is also set to 1 by setting of the RESET bit, enabling SWnRST, or by a system reset.<br>2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.<br>3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit.<br><i>SCI mode:</i><br>0 SCITD is full.<br>1 SCITD is ready to receive the next character.<br><i>LIN mode:</i><br>0 Multi-buffers are full.<br>1 Multi-buffers are ready to receive the next character.<br>For more information on transmit interrupt handling, see the SCI document for compatibility mode and <a href="#">Section 25.7.9</a> for LIN mode. |

**Table 25-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | TOA3WUS  | 0     | <p>Timeout after three wakeup signals flag. This bit is effective in LIN mode only. This flag is set if there is no synch break received after three wakeup signals and a period of 1.5 seconds has passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 25.11.3</a> for more information.</p> <p><i>Read:</i> No timeout occurred after three wakeup signals.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                            |
|     |          | 1     | <p><i>Read:</i> Timeout occurred after three wakeup signals and 1.5 seconds time.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 6   | TOAWUS   | 0     | <p>Timeout after wakeup signal flag. This bit is effective in LIN mode only. This bit is set if there is no synch break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 25.11.3</a> for more information.</p> <p><i>Read:</i> No timeout occurred after one wakeup signal (150 ms).</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                |
|     |          | 1     | <p><i>Read:</i> Timeout occurred after one wakeup signal.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5   | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 4   | TIMEOUT  | 0     | <p>LIN bus idle timeout flag. This bit is effective in LIN mode only. This bit is set earliest after at least four seconds of bus inactivity. Bus inactivity is defined as no transactions between recessive and dominant (and vice versa). This bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>See <a href="#">Section 25.7.7</a> for more information.</p> <p><i>Read:</i> No bus idle has been detected since this bit was last cleared.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                    |
|     |          | 1     | <p><i>Read:</i> A LIN bus idle has been detected.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 3   | BUSY     | 0     | <p>Bus busy flag. This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI/LIN clears the BUSY bit. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI/LIN receiver, but this bit can also be cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SWnRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> </ul> <p>The receiver is not currently receiving a frame.</p> |
|     |          | 1     | <p>The receiver is currently receiving a frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 25-19. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|--------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | IDLE   | 0     | SCI receiver in idle state. This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs: <ul style="list-style-type: none"> <li>• A system reset</li> <li>• An SCI software reset</li> <li>• A power down</li> <li>• The RX pin is configured as a general I/O pin</li> </ul> The idle period has been detected; the SCI is ready to receive.                                                                                                                                                                                                                     |
|     |        | 1     | The idle period has not been detected; the SCI will not receive any data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 1   | WAKEUP | 0     | Wakeup flag. This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT[2]) is set. It is cleared by the following: <ul style="list-style-type: none"> <li>• Setting of the SWnRST bit</li> <li>• Setting of the RESET bit</li> <li>• A system reset</li> <li>• Writing a 1 to this bit</li> <li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> For compatibility mode, see the SCI document for more information on low-power mode.<br><i>Read:</i> The module will not wake up from power-down mode.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                   |
|     |        | 1     | <i>Read:</i> Wake up from power-down mode.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0   | BRKDT  | 0     | SCI break-detect flag. This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit is set. The BRKDT bit is reset by the following: <ul style="list-style-type: none"> <li>• Setting of the SWnRST bit</li> <li>• Setting of the RESET bit</li> <li>• A system reset</li> <li>• Writing a 1 to this bit</li> <li>• Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <i>Read:</i> No break condition has been detected since the last clear.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|     |        | 1     | <i>Read:</i> A break condition has been detected.<br><i>Write:</i> The bit is cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 25.13.9 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 25-35 and Table 25-20 illustrate this register.

**Figure 25-35. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]**

LEGEND: R = Read only; -n = value after reset

**Table 25-20. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

These bits set the SCI character length from 1 to 8 bits.</p> <p><b>In non-buffered SCI and buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified.</b></p> <p><b>Data written to the SCITD should be right justified but does not need to be padded with leading zeros.</b></p> <p>The character is 1 bit long.</p> <p>The character is 2 bits long.</p> <p>The character is 3 bits long.</p> <p>The character is 4 bits long.</p> <p>The character is 5 bits long.</p> <p>The character is 6 bits long.</p> <p>The character is 7 bits long.</p> <p>The character is 8 bits long.</p>                                                                                                                                                                                    |

### 25.13.12 Baud Rate Selection Register (BRS)

This section describes the baud rate selection register. [Figure 25-38](#) and [Table 25-23](#) illustrate this register.

**Figure 25-38. Baud Rate Selection Register (BRS) [offset = 2Ch]**

| 31    | Reserved    | 0          | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 30-28 | U           | 0-2h       | SCI/LIN super fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are an additional fractional part for the baud rate specification. These bits allow a super-fine tuning of the fractional baud rate with seven more intermediate values for each of the M fractional divider values. See <a href="#">Section 25.7.4.1</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 27-24 | M           | 0-3h       | SCI/LIN 4-bit fractional divider selection. These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. See <a href="#">Section 25.7.4.1</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 23-0  | PRESCALER P | 0-FF FFFFh | <p>These bits are used to select a baud rate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatibility.</p> <p>The SCI/LIN has an internally generated serial clock determined by the VCLK and the prescalers P and M in this register. The LIN uses the 24-bit integer prescaler P value of this register to select one of over 16,700,000. The additional 4-bit fractional divider M refines the baud rate selection PRESCALER[27:24].</p> <p><b>NOTE: In LIN mode, ONLY the asynchronous mode and baud rate values are used.</b></p> <p>The baud rate can be calculated using the following formulas:</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{16 \left( P + 1 + \frac{M}{16} \right)} \right) \quad (48)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{P + 1} \right) \quad (49)$ <p>For P = 0,</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{32} \right) \quad (50)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{2} \right) \quad (51)$ <p><a href="#">Table 25-24</a> contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.</p> |

**Table 25-24. Comparative Baud Values for Different P Values, Asynchronous Mode<sup>(1)(2)</sup>**

| 24-Bit Register Value |        | Baud Selected |        | Percent Error |
|-----------------------|--------|---------------|--------|---------------|
| Decimal               | Hex    | Ideal         | Actual |               |
| 26                    | 00001A | 115200        | 115740 | 0.47          |
| 53                    | 000035 | 57600         | 57870  | 0.47          |
| 80                    | 000050 | 38400         | 38580  | 0.47          |
| 162                   | 0000A2 | 19200         | 19172  | -0.15         |
| 299                   | 00012B | 10400         | 10417  | 0.16          |
| 325                   | 000145 | 9600          | 9586   | -0.15         |
| 399                   | 00018F | 7812.5        | 7812.5 | 0.00          |
| 650                   | 00028A | 4800          | 4800   | 0.00          |
| 15624                 | 003BA0 | 200           | 200    | 0.00          |
| 624999                | 098967 | 5             | 5      | 0.00          |

<sup>(1)</sup> VCLK = 50 MHz

<sup>(2)</sup> Values are in decimal except for column 2.

### 25.13.13 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored. These three registers are available in SCI mode only.

#### 25.13.13.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register. [Figure 25-39](#) and [Table 25-25](#) illustrate this register.

**Figure 25-39. Receiver Emulation Data Buffer (SCIED) [offset = 30h]**

LEGEND: R = Read only; -n = value after reset

**Table 25-25. Receiver Emulation Data Buffer (SCIED) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                             |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                  |
| 7-0  | ED       | 0-FFh | Emulator data. This bit is effective in SCI-compatible mode only. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag. |

### 25.13.13.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. [Figure 25-40](#) and [Table 25-26](#) illustrate this register.

**Figure 25-40. Receiver Data Buffer (SCIRD) [offset = 34h]**

LEGEND: R = Read only; -n = value after reset

**Table 25-26. Receiver Data Buffer (SCIRD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                             |
| 7-0  | RD       | 0-FFh | Receiver data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set.<br><b>Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.</b> |

**NOTE:** When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified.

### 25.13.13.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. [Figure 25-41](#) and [Table 25-27](#) illustrate this register.

**Figure 25-41. Transmit Data Buffer Register (SCITD) [offset = 38h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-27. Transmit Data Buffer Register (SCITD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                         |
| 7-0  | TD       | 0-FFh | Transmit data. This bit is effective in SCI-compatible mode only. Data to be transmitted is written to the SCITD register. The transfer of data from this register to the transmit shift register SCITXSHF sets the TXRDY flag, which indicates that SCITD is ready to be loaded with another byte of data.<br><b>Note: If SET TX INT is set, this data transfer also causes an interrupt.</b> |

**NOTE:** Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

### 25.13.14 SCI Pin I/O Control Register 0 (SCIPIO0)

[Figure 25-42](#) and [Table 25-28](#) illustrate this register.

**Figure 25-42. SCI Pin I/O Control Register 0 (SCIPIO0) [offset = 3Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-28. SCI Pin I/O Control Register 0 (SCIPIO0) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                   |
|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                        |
| 2    | TX FUNC  | 0<br>1 | Transfer function. This bit is effective in LIN or SCI mode. This bit defines the function of pin LINTX.<br>LINTX is a general-purpose digital I/O pin.<br>LINTX is the SCI/LIN transmit pin. |
| 1    | RX FUNC  | 0<br>1 | Receive function. This bit is effective in LIN or SCI mode. This bit defines the function of pin LINRX.<br>LINRX is a general-purpose digital I/O pin.<br>LINRX is the SCI/LIN receive pin.   |
| 0    | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                        |

### 25.13.15 SCI Pin I/O Control Register 1 (SCIPIO1)

Figure 25-43 and Table 25-29 illustrate this register.

**Figure 25-43. SCI Pin I/O Control Register 1 (SCIPIO1) [offset = 40h]**

|          |  |  |  |  |  |  |  |  |  |        |   |        |   |          |  |   |

**Table 25-29. SCI Pin I/O Control Register 1 (SCIPIO1) Field Descriptions**

| Bit  | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                |
|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                     |
| 2    | TX DIR   | 0<br>1 | Transmit pin direction. This bit is effective in LIN or SCI mode. This bit determines the data direction on the LINTX pin if it is configured with general-purpose I/O functionality (TX FUNC = 0). See Table 25-30 for the LINTX pin control with this bit and others.<br>LINTX is a general-purpose input pin.<br>LINTX is a general-purpose output pin. |
| 1    | RX DIR   | 0<br>1 | Receive pin direction. This bit is effective in LIN or SCI mode. This bit determines the data direction on the LINRX pin if it is configured with general-purpose I/O functionality (RX FUNC = 0). See Table 25-31 for the LINRX pin control with this bit and others.<br>LINRX is a general-purpose input pin.<br>LINRX is a general-purpose output pin.  |
| 0    | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                     |

**Table 25-30. LINTX Pin Control**

| Function                     | TX IN <sup>(1)</sup> | TX OUT | TX FUNC | TX DIR |
|------------------------------|----------------------|--------|---------|--------|
| LINTX                        | X                    | X      | 1       | X      |
| General purpose input        | X                    | X      | 0       | 0      |
| General purpose output, high | X                    | 1      | 0       | 1      |
| General purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> TX IN is a read-only bit. Its value always reflects the level of the SCITX pin.

**Table 25-31. LINRX Pin Control**

| Function                     | RX IN <sup>(1)</sup> | RX OUT | RX FUNC | RX DIR |
|------------------------------|----------------------|--------|---------|--------|
| LINRX                        | X                    | X      | 1       | X      |
| General purpose input        | X                    | X      | 0       | 0      |
| General purpose output, high | X                    | 1      | 0       | 1      |
| General purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> RX IN is a read-only bit. Its value always reflects the level of the SCIRX pin.

### 25.13.17 SCI Pin I/O Control Register 3 (SCIPIO3)

Figure 25-45 and Table 25-33 illustrate this register.

**Figure 25-45. SCI Pin I/O Control Register 3 (SCIPIO3) [offset = 48h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 25-33. SCI Pin I/O Control Register 3 (SCIPIO3) Field Descriptions**

| Bit  | Field    | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

LEGEND: R/W = Read/Write; R = Read only; WL = Write in LIN mode only; -n = value after reset

**Table 25-42. LIN Mask Register (LINMASK) Field Descriptions**

| Bit   | Field      | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved   | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 23-16 | RX ID MASK | 0-FFh | Receive ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the RX ID MASK will set the ID RX flag and trigger an ID interrupt if enabled (SET ID INT in SCISSETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used in the compare.   |
| 15-8  | Reserved   | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 7-0   | TX ID MASK | 0-FFh | Transmit ID mask. These bits are effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID MASK will set the ID TX flag and trigger an ID interrupt if enabled (SET ID INT in SCISSETINT). A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore is not used for the compare. |

### 25.13.27 LIN Identification Register (LINID)

Figure 25-55 and Table 25-43 illustrate this register.

**Figure 25-55. LIN Identification Register (LINID) [offset = 70h]**

**Table 25-43. LIN Identification Register (LINID) Field Descriptions**

| Bit   | Field             | Value | Description                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved          | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                            |
| 23-16 | RECEIVED ID       | 0-FFh | Received identification. These bits are effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match.                                                |
| 15-8  | ID-SLAVETASK BYTE | 0-FFh | ID-SlaveTask Byte. These bits are effective in LIN mode only. This field contains the identifier to which the received ID of an incoming header will be compared to decide whether a receive response, a transmit response, or no action needs to be performed by the LIN node when a header with that particular ID is received. |
| 7-0   | ID BYTE           | 0-FFh | ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a master node, a write to this register by the CPU initiates a header transmission. For a slave task, this byte is used for message filtering when HGEN CTRL = 0.                                                                     |

**NOTE:** For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

### 25.13.28 LIN Transmit Buffer 0 Register (LINTD0)

Figure 25-56 and Table 25-44 illustrate this register.

| 12-0  | MBR      | 0-1FFF <sub>h</sub> | <p>Maximum baud rate prescaler. This bit is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see <a href="#">Section 25.7.5.2</a>) of a slave module if the ADAPT bit is set. In this way, a SCI/LIN slave using an automatic or select bit rate modes detects any LIN bus legal rate automatically.</p> <p>The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte could mistakenly be detected as a sync break.</p> <p>The default value for a 70Mhz VCLK is 0xDAC.</p> <p>This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20 kHz rate.</p> $MBR = \frac{0.9 \times VCLK}{maxbaudrate}$ |

(52)

### 25.13.31 Input/Output Error Enable (IODFTCTRL) Register

All the bits in the IODFTCTRL register are used in IODFT (I/O design for test) mode only. [Figure 25-59](#) and [Table 25-47](#) illustrate this register. After the basic SCI/LIN module configuration, enable the required Error mode to be created followed by IODFT Key enable.

- NOTE:**
- 1) All the bits are used in IODFT mode only.
  - 2) Each IODFT are expected to be checked individually.
  - 3) ISFE Error will not be Flagged during IODFT mode.

## 25.14 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

### 25.14.1 GPIO Functionality

Figure 25-60 illustrates the GPIO functionality.

**Figure 25-60. GPIO Functionality**

### 25.14.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

### 25.14.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIPIO7 register (Section 25.13.21). In this case, if the PSL (pull select) bit in the SCIPIO8 register (Section 25.13.22) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is permanently enabled in this device.

---

**NOTE:** The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically.

---

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIPIO1; Section 25.13.15) AND the open-drain feature is not enabled in the SCIPIO6 register (Section 25.13.20).

### 25.14.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low) if a high signal is being driven on to the pin.

---

**NOTE:** The open-drain feature is available only in I/O mode (SCIPIO0; Section 25.13.14).

---

### 25.14.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 25-48.

**Table 25-48. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins<sup>(1)</sup>**

| Device under Reset? | Pin Direction (DIR) <sup>(2)</sup> | Pull Disable (PULDIS) <sup>(3)</sup> | Pull Select (PULSEL) <sup>(4)</sup> | Pull Control | Output Buffer | Input Buffer |
|---------------------|------------------------------------|--------------------------------------|-------------------------------------|--------------|---------------|--------------|
| Yes                 | X                                  | X                                    | X                                   | Enabled      | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 0                                   | Pull down    | Disabled      | Enabled      |
| No                  | 0                                  | 0                                    | 1                                   | Pull up      | Disabled      | Enabled      |
| No                  | 0                                  | 1                                    | 0                                   | Disabled     | Disabled      | Enabled      |
| No                  | 0                                  | 1                                    | 1                                   | Disabled     | Disabled      | Enabled      |
| No                  | 1                                  | X                                    | X                                   | Disabled     | Enabled       | Enabled      |

<sup>(1)</sup> X = Don't care

<sup>(2)</sup> DIR = 0 for input, = 1 for output

<sup>(3)</sup> PULDIS = 0 for enabling pull control, = 1 for disabling pull control

<sup>(4)</sup> PULSEL = 0 for pull-down functionality, = 1 for pull-up functionality

## Serial Communication Interface (SCI) Module

This chapter contains the description of the serial communication interface (SCI) module.

## 26.1 Introduction

The SCI module is a universal asynchronous receiver-transmitter that implements the standard nonreturn to zero format. The SCI can be used to communicate, for example, through an RS-232 port or over a K-line.

### 26.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard nonreturn to zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode with no CLK pin
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- Capability to use Direct Memory Access (DMA) for transmit and receive data
- Four error flags and Five status flags provide detailed information regarding SCI events
- Two external pins: SCIRX and SCITX

---

**NOTE:** SCI module does not support UART Hardware Flow Control. This feature can be implemented in Software using a General Purpose I/O pin.

---

### 26.1.2 Block Diagram

Three Major components of the SCI Module are:

- Transmitter
- Baud Clock Generator
- Receiver

**Transmitter (TX)** contains two major registers to perform double buffering:

- The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
- The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the SCITX pin, one bit at a time.

#### Baud Clock Generator

- A programmable baud generator produces a baud clock scaled from VCLK.

**Receiver (RX)** contains two major registers to perform double buffering:

- The receiver shift register (SCIRXSHF) shifts data in from the SCIRX pin one bit at a time and transfers completed data into the receive data buffer.
- The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has its own separate enable and interrupt bits. The receiver and transmitter may each be operated independently or simultaneously in full duplex mode.

To ensure data integrity, the SCI checks the data it receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 26-1 shows the detailed SCI block diagram.

Figure 26-1. Detailed SCI Block Diagram

## 26.2 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI are user configurable. The list below describes these configuration options:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

### 26.2.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 26-2](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected via the PARITY ENA bit. Both examples in [Figure 26-2](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to ensure synchronization between communicating devices. Two stop bits are transmitted if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 26-2](#) use one stop bit per frame.

**Figure 26-2. Typical SCI Data Frame Formats**

### 26.2.2 SCI Timing Mode

The SCI can be configured to use asynchronous or isosynchronous timing using TIMING MODE bit in SCIGCR1 register.

### 26.2.2.1 Asynchronous Timing Mode

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the SCIRX pin are of logic level 0. As soon as a falling edge is detected on SCIRX, the SCI assumes that a frame is being received and synchronizes itself to the bus.

To prevent interpreting noise as Start bit SCI expects SCIRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the SCIRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises.

Figure 26-3 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the SCITX pin. The transmitter then holds the current bit value on SCITX for 16 SCI baud clock periods.

**Figure 26-3. Asynchronous Communication Bit Timing**

### 26.2.2.2 Isosynchronous Timing Mode

In isosynchronous timing mode, each bit in a frame has a duration of exactly 1 baud clock period and therefore consists of a single sample. With this timing configuration, the transmitter and receiver are required to make use of the SCICLK pin to synchronize communication with other SCI. **This mode is not fully supported on this device because SCICLK pin is not available.**

### 26.2.3 SCI Baud Rate

The SCI has an internally generated serial clock determined by the peripheral VCLK and the prescalers BAUD. The SCI uses the 24-bit integer prescaler BAUD value of the BRS register to select the required baud rates.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{16 * (\text{BAUD} + 1)}$$

For BAUD = 0,

$$\text{Asynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (53)$$

In isosynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$\text{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{\text{BAUD} + 1}$$

For BAUD = 0,

$$\text{Isosynchronous baud value} = \frac{\text{VCLK Frequency}}{32} \quad (54)$$

### 26.2.4 SCI Multiprocessor Communication Modes

In some applications, the SCI may be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data may be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when they are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor Communication Modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received via the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

---

**NOTE: Avoid Transmitting Simultaneously on the Same Serial Bus**

The system designer must ensure that devices connected to the same serial bus line do not attempt to transmit simultaneously. If two devices are transmitting different data, the resulting bus conflict could damage the device..

---

### 26.2.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 26-4 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1 : Write a 1 to the TXWAKE bit.

Step 2 : Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3 : Wait for the SCI to clear the TXWAKE flag.

Step 4 : Write the address value to SCITD.

As indicated by Step 3, software should wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time it sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear it.

When idle-line multiprocessor communications are used, software must ensure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also ensure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions will result in data interpretation errors by other devices receiving the transmission.

**Figure 26-4. Idle-Line Multiprocessor Communication Format**

### 26.2.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. [Figure 26-5](#) illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 26-5. Address-Bit Multiprocessor Communication Format**

## 26.3 SCI Interrupts

The SCI module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 26-6](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable and disable the interrupt in the SCISSETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 26-6. General Interrupt Scheme**

**Figure 26-7. Interrupt Generation for Given Flags**

### 26.3.1 Transmit Interrupt

To use transmit interrupt functionality, SET TX INT bit must be enabled and SET TX DMA bit must be cleared. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty. If the SET TX INT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. Transmit Interrupt is not generated immediately after setting the SET TX INT bit unlike transmit DMA request. Transmit Interrupt is generated only after the first transfer from SCITD to SCITXSHF, that is first data has to be written to SCITD by the User before any interrupt gets generated. To transmit further data the user can write data to SCITD in the transmit Interrupt service routine.

Writing data to the SCITD register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLR TX INT bit; however, when the SET TX INT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD, by disabling the transmitter via the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 26.3.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SET RX INT bit. If the SET RX INT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with both SCI and a DMA controller, the bits SET RX DMA ALL and SET RX DMA must be cleared to select interrupt functionality.

### 26.3.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SET WAKEUP INT), wakeup interrupt is triggered once WAKEUP flag is set.

### 26.3.4 Error Interrupts

The following error detection features are supported with Interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)

If any of these errors (PE, FE, BRKDT, OE) is flagged, an interrupt for the flagged errors will be generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register. Further details on these flags are explained in SCIFLR register description.

The SCI module supports the following 7 interrupts as listed in [Table 26-1](#).

**Table 26-1. SCI Interrupts**

| Offset <sup>(1)</sup> | Interrupt          |
|-----------------------|--------------------|
| 0                     | Reserved           |
| 1                     | Wakeup             |
| 2                     | Reserved           |
| 3                     | Parity error       |
| 4                     | Reserved           |
| 5                     | Reserved           |
| 6                     | Frame error        |
| 7                     | Break detect error |
| 8                     | Reserved           |
| 9                     | Overrun error      |
| 10                    | Reserved           |
| 11                    | Receive            |
| 12                    | Transmit           |
| 13-15                 | Reserved           |

<sup>(1)</sup> Offset 1 is the highest priority. Offset 16 is the lowest priority.

## 26.4 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI module. Refer to the DMA module chapter for DMA module configurations.

### 26.4.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SET RX DMA/CLR RX DMA bits, respectively.

The receiver DMA request is set when a frame is received successfully and DMA functionality has been previously enabled. The RXRDY flag is set when the SCI transfers newly received data from the SCIRXSHF register to the SCIRD buffer. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive DMA requests are enabled by the SET RX INT bit.

Parity, overrun, break detect, wake-up, and framing errors generate an error interrupt request immediately upon detection, if enabled, even if the device is in the process of a DMA data transfer. The DMA transfer is postponed until the error interrupt is served. The error interrupt can delete this particular DMA request by reading the receive buffer.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames. This is controlled by an extra select bit SET RX DMA ALL.

If the SET RX DMA ALL bit is set and the SET RX DMA bit is set when the SCI sets the RXRDY flag, then a receive DMA request is generated for address and data frames.

If the SET RX DMA ALL bit is cleared and the SET RX DMA bit is set when the SCI sets the RXRDY flag upon receipt of a data frame, then a receive DMA request is generated. Receive interrupt requests are generated for address frames.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received. [Table 26-2](#) specifies the bit values for DMA requests in multiprocessor modes.

**Table 26-2. DMA and Interrupt Requests in Multiprocessor Modes**

| SET RX INT | SET RX DMA | SET RX DMA ALL | ADDR FRAME INT | ADDR FRAME DMA | DATA FRAME INT | DATA FRAME DMA |
|------------|------------|----------------|----------------|----------------|----------------|----------------|
| 0          | 0          | x              | N              | N              | N              | N              |
| 0          | 1          | 0              | Y              | N              | N              | Y              |
| 0          | 1          | 1              | N              | Y              | N              | Y              |
| 1          | 0          | x              | Y              | N              | Y              | N              |
| 1          | 1          | 0              | Y              | N              | Y              | Y              |
| 1          | 1          | 1              | Y              | Y              | Y              | Y              |

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET RX DMA ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

### 26.4.2 Transmit DMA Requests

DMA functionality is enabled and disabled by the CPU with the SET TX DMA and CLR TX DMA bits, respectively.

The TXRDY flag is set when the SCI transfers the contents of SCITD to SCITXSHF. The TXRDY flag indicates that SCITD is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD and SCITXSHF registers are empty.

Transmit DMA requests are enabled by the setting SET TX DMA and SET TX INT bits. If the SET TX DMA bit is set, then a TX DMA request is sent to the DMA when data is written to SCITD and TXRDY is set. The DMA will write the first byte to the transmit buffer.

## 26.5 SCI Configurations

Before the SCI sends or receives data, its registers should be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until it is programmed to 1. Therefore, all SCI configuration should be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software should perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the SCIRX and SCITX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until its current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 26.5.1](#) and [Section 26.5.2](#)).

### 26.5.1 Receiving Data

The SCI receiver is enabled to receive messages if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the SCIRX pin functions as a general-purpose I/O pin rather than as an SCI function pin. After a valid idle period is detected, data is automatically received as it arrives on the SCIRX pin.

SCI sets the RXRDY bit when it transfers newly received data from SCIRXSHF to SCIRD. The SCI clears the RXRDY bit after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the SCI sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wake-up and break-detect status bits are also set if one of these errors occurs, but they do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from SCIRD register once RXRDY is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET RX INT bit is set. To use the DMA method, the SET RX DMA bit is set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

## 26.5.2 Transmitting Data

The SCI transmitter is enabled if both the TX FUNC bit and the TXENA bit are set to 1. If the TX FUNC bit is not set, the SCITX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

SCI waits for data to be written to SCITD, transfers it to SCITXSHF, and transmits the data. The TXRDY and TX EMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TX EMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, the SET TX INT bit is set. To use the DMA method, the SET TX DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request should be halted. This can either be done by disabling the transmit interrupt (CLR TX INT) / DMA request (CLR TX DMA bit) or by disabling the transmitter (clear TXENA bit).

---

**NOTE:** The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

## 26.6 SCI Low-Power Mode

The SCI can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI. During global low-power mode, all clocks to the SCI are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wake-up interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the SCIRX pin and also this clears the POWERDOWN bit. If wake-up interrupt is disabled, then the SCI immediately enters low-power mode whenever it is requested and also any activity on the SCIRX pin does not cause the SCI to exit low-power mode.

---

**NOTE: Enabling Local Low-Power Mode During Receive and Transmit**

If the wake-up interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wake-up interrupt to clear the power-down bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wake-up interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

### 26.6.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if RX INT ENA is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior may be enhanced to provide selective indication of new data. When SCI receives an address frame that does not match its address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI will load SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI should check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. This bit is set to 1 if the current value in SCIRD is an address and set to 0 if SCIRD contains data. If the RXWAKE bit is set, then software should check the address in SCIRD against its own address. If it is still being addressed, then sleep mode should remain disabled. Otherwise, the SLEEP bit should be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. These interrupts would otherwise require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 26-11](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software should not change the value of the SLEEP bit and should continue to poll RXRDY.

## 26.7 SCI Control Registers

These registers are accessible in 8-, 16-, and 32-bit reads or writes. The SCI is controlled and accessed through the registers listed in [Table 26-3](#). Among the features that can be programmed are the SCI communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration. The base address for the control registers is FFF7 E500h.

**Table 26-3. SCI Control Registers Summary**

| Offset | Acronym        | Register Description               | Section                           |
|--------|----------------|------------------------------------|-----------------------------------|
| 00h    | SCIGCR0        | SCI Global Control Register 0      | <a href="#">Section 26.7.1</a>    |
| 04h    | SCIGCR1        | SCI Global Control Register 1      | <a href="#">Section 26.7.2</a>    |
| 0Ch    | SCISSETINT     | SCI Set Interrupt Register         | <a href="#">Section 26.7.3</a>    |
| 10h    | SCICLEARINT    | SCI Clear Interrupt Register       | <a href="#">Section 26.7.4</a>    |
| 14h    | SCISSETINTLVL  | SCI Set Interrupt Level Register   | <a href="#">Section 26.7.5</a>    |
| 18h    | SCICLEARINTLVL | SCI Clear Interrupt Level Register | <a href="#">Section 26.7.6</a>    |

## 26.7.1 SCI Global Control Register 0 (SCIGCR0)

The SCIGCR0 register defines the module reset. [Figure 26-8](#) and [Table 26-4](#) illustrate this register.

**Figure 26-8. SCI Global Control Register 0 (SCIGCR0) [offset = 00]**

LEGEND: R = Read only; R/WP = Read/Write in privileged mode only; -n = value after reset

**Table 26-4. SCI Global Control Register 0 (SCIGCR0) Field Descriptions**

| Bit                                              | Field    | Value | Description                                                |

## 26.7.2 SCI Global Control Register 1 (SCIGCR1)

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI. [Figure 26-9](#) and [Table 26-5](#) illustrate this register.

**NOTE:** The SCIGCR1 Control Register Bits should not be changed during Frame Transmission or Reception.

| 17    | CONT     | 0<br>1 | Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI operates when the program is suspended. The<br>When debug mode is entered, the SCI state machine is frozen. Transmissions are halted and resume when debug mode is exited.<br>When debug mode is entered, the SCI continues to operate until the current transmit and receive functions are complete.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 26-5. SCI Global Control Register 1 (SCIGCR1) Field Descriptions (continued)**

| Bit   | Field     | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|-----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16    | LOOP BACK | 0<br>1 | <p>Loopback bit. The self-checking option for the SCI can be selected with this bit. If the SCITX and SCIRX pins are configured with SCI functionality, then the SCITX pin is internally connected to the SCIRX pin. Externally, during loop back operation, the SCITX pin outputs a high value and the SCIRX pin is in a high-impedance state. If this bit value is changed while the SCI is transmitting or receiving data, errors may result.</p> <p>0 Loop back mode is disabled.</p> <p>1 Loop back mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15-10 | Reserved  | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 9     | POWERDOWN | 0<br>1 | <p>Power down. When the POWERDOWN bit is set, the SCI attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wake-up interrupt is enabled, then the SCI immediately asserts an error interrupt to prevent low-power mode from being entered. Only Privilege mode writes allowed.</p> <p>0 Normal operation.</p> <p>1 Low-power mode is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 8     | SLEEP     | 0<br>1 | <p>SCI sleep. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>0 Sleep mode is disabled.</p> <p>1 Sleep mode is enabled.</p> <p><b>Note: The receiver still operates when the SLEEP bit is set; however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags (see Table 26-11 ) are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition.</b></p> <p><b>Note: The SLEEP bit is not automatically cleared when an address byte is detected.</b></p> <p>See Section 26.6 for more information on using the SLEEP bit for multiprocessor communication.</p> |
| 7     | SWnRST    | 0<br>1 | <p>Software reset (active low).</p> <p>0 The SCI is in its reset state; no data will be transmitted or received. Writing a 0 to this bit initializes the SCI state machines and operating flags as defined in Table 26-11 and Table 26-12. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>1 The SCI is in its ready state; transmission and reception can be done. After this bit is set to 1, the configuration of the module should not change.</p> <p><b>Note: The SCI should only be configured while SWnRESET = 0.</b></p>                                                                                                                                                                                                                                                                                                                                                                                      |
| 6     | Reserved  | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 5     | CLOCK     | 0<br>1 | <p>SCI internal clock enable. The CLOCK bit determines the source of the module clock on the SCICLK pin.</p> <p>0 The external SCICLK is the clock source.</p> <p>1 The internal SCICLK is the clock source.</p> <p><b>Note: If an external clock is selected, then the internal baud rate generator and baud rate registers are bypassed. The maximum frequency allowed for an externally sourced SCI clock is VCLK/16.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 4     | STOP      | 0<br>1 | <p>SCI number of stop bits per frame.</p> <p>0 One stop bit is used.</p> <p>1 Two stop bits are used.</p> <p><b>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 26.7.3 SCI Set Interrupt Register (SCISSETINT)

Figure 26-10 and Table 26-6 illustrate this register. SCISSETINT register is used to enable the required interrupts supported by the module.

**Table 26-6. SCI Set Interrupt Register (SCISSETINT) Field Descriptions (continued)**

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|----------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16    | SET TX DMA     | 0     | Set transmit DMA. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on the SET TX INT bit (SCISSETINT[8]).<br><i>Read:</i> Transmit DMA request is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                             |
|       |                | 1     | <i>Read and write:</i> Transmit DMA request is enabled.                                                                                                                                                                                                                                                                                                                                                       |
| 15-10 | Reserved       | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                        |
| 9     | SET RX INT     | 0     | Receiver interrupt enable. Setting this bit enables the SCI to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                           |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                               |
| 8     | SET TX INT     | 0     | Set transmitter interrupt. Setting this bit enables the SCI to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                           |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                               |
| 7-2   | Reserved       | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                        |
| 1     | SET WAKEUP INT | 0     | Set wakeup interrupt. Setting this bit enables the SCI to generate a wakeup interrupt and thereby exit low-power mode. If enabled, the wakeup interrupt is asserted when local lowpower mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect. |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                               |
| 0     | SET BRKDT INT  | 0     | Set break detect interrupt. Setting this bit enables the SCI to generate an error interrupt if a break condition is detected on the SCIRX pin.<br><i>Read:</i> The interrupt is disabled.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                             |
|       |                | 1     | <i>Read or write:</i> The interrupt is enabled.                                                                                                                                                                                                                                                                                                                                                               |

## 26.7.4 SCI Clear Interrupt Register (SCICLEARINT)

Figure 26-11 and Table 26-7 illustrate this register. SCICLEARINT register is used to clear the selected enabled interrupts with out accessing SCISSETINT register.

**Figure 26-11. SCI Clear Interrupt Register (SCICLEARINT) [offset = 10h]**

| 31-27 | Reserved |       | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 26    | FE       | 0     | <p>Framing error flag. This bit is set when an expected stop bit is not found. In SCI compatibility mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt, if the SET FE INT bit (SCISSETINT[26]) is set. The framing error flag is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> <li>Reception of a new character</li> </ul> <p>In multi-buffer mode, the frame is defined in the SCIFORMAT register.</p> <p><i>Read:</i> No framing error has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> |
|       |          | 1     | <p><i>Read:</i> A framing error has been detected since the last clear.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25    | OE       | 0     | <p>Overrun error flag. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD. Detection of an overrun error causes the SCI to generate an error interrupt if the SET OE INT bit (SCISSETINT[25]) is set. The OE flag is reset by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><i>Read:</i> No overrun error has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                                                                                                                                                                                                 |
|       |          | 1     | <p><i>Read:</i> An overrun error has been detected since the last clear.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24    | PE       |       | Parity error flag. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. If the parity function is disabled (SCIGCR[2] = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the SCI to generate an error interrupt if the SET PE INT bit (SCISSETINT[24]) is set. The PE bit is reset by the following: <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reception of a new character</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> |
|       |          | 0     | <i>Read:</i> No parity error has been detected since the last clear.<br><i>Write:</i> Writing a 0 to this bit has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 9   | RXRDY    | 0     | <p>Receiver ready flag. The receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU or DMA. The SCI generates a receive interrupt when RXRDY flag bit is set if the SET RX INT bit (SCISSETINT[9]) is set; RXRDY is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the SCIRD register in compatibility mode</li> <li>Reading the last data byte RDY of the response in SCI mode</li> </ul> <p><b>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b></p> <p><i>Read:</i> No new data is in SCIRD.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                                                                                                                |
|     |          | 1     | <p><i>Read:</i> New data is ready to be read from SCIRD.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 8   | TXRDY    | 0     | <p>Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer is ready to get another character from a CPU or DMA write.</p> <p>Writing data to SCITD automatically clears this bit. This bit is set after the data of the TX buffer is shifted into the SCITXSHF register. This event can trigger a transmit interrupt after data is copied to the TX shift register SCITXSHF, if the SET TX INT bit (SCISSETINT[8]) is set.</p> <p><b>Note: 1) TXRDY is also set to 1 by setting of the RESET bit, setting of the RESET bit, or by a system reset.</b></p> <p><b>2) The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</b></p> <p><b>3) The transmit interrupt request can be eliminated until the next series of data written into the transmit buffers SCITD0 and SCITD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1[25]).</b></p> <p>SCITD is full.</p> |
|     |          | 1     | <p>SCITD is ready to receive the next character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7-4 | Reserved | 0     | <p>Reads return 0. Writes have no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3   | BUSY     | 0     | <p>Bus busy flag. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the SCI clears the BUSY bit. If the SET WAKEUP INT bit (SCISSETINT[2]) is set and power down is requested while this bit is set, the SCI automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver, but this bit can also be cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset occurring</li> </ul> <p>The receiver is not currently receiving a frame.</p>                                                                                                                                                                                                                                                     |
|     |          | 1     | <p>The receiver is currently receiving a frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2   | IDLE     | 0     | <p>SCI receiver in idle state. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters the idle state if one of the following events occurs:</p> <ul style="list-style-type: none"> <li>A system reset</li> <li>An SCI software reset</li> <li>A power down</li> <li>The RX pin is configured as a general I/O pin</li> </ul> <p>The idle period has been detected; the SCI is ready to receive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|     |          | 1     | <p>The idle period has not been detected; the SCI will not receive any data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 26-10. SCI Flags Register (SCIFLR) Field Descriptions (continued)**

| Bit | Field  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----|--------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | WAKEUP | 0     | <p>Wakeup flag. This bit is set by the SCI when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT[2]) is set. It is cleared by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p>For compatibility mode, see the SCI document for more information on low-power mode.</p> <p><i>Read:</i> The module will not wake up from power-down mode.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p>                                                                                                        |
|     |        | 1     | <p><i>Read:</i> Wake up from power-down mode.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0   | BRKDT  | 0     | <p>SCI break-detect flag. This bit is set when the SCI detects a break condition on the SCIRX pin. A break condition occurs when the SCIRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the SET BRKDT INT bit (SCISSETINT[0]) is set. The BRKDT bit is reset by the following:</p> <ul style="list-style-type: none"> <li>Setting of the SW nRST bit</li> <li>Setting of the RESET bit</li> <li>A system reset</li> <li>Writing a 1 to this bit</li> <li>Reading the corresponding interrupt offset in SCIINTVECT0/1</li> </ul> <p><i>Read:</i> No break condition has been detected since the last clear.</p> <p><i>Write:</i> Writing a 0 to this bit has no effect.</p> |
|     |        | 1     | <p><i>Read:</i> A break condition has been detected.</p> <p><i>Write:</i> The bit is cleared to 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 26-11. SCI Receiver Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| FE       | SCIFLR   | 26  | 0                                    |
| OE       | SCIFLR   | 25  | 0                                    |
| PE       | SCIFLR   | 24  | 0                                    |
| RXWAKE   | SCIFLR   | 12  | 0                                    |
| RXRDY    | SCIFLR   | 9   | 0                                    |
| BRKDT    | SCIFLR   | 0   | 0                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

**Table 26-12. SCI Transmitter Status Flags**

| SCI Flag | Register | Bit | Value After SW nRESET <sup>(1)</sup> |
|----------|----------|-----|--------------------------------------|
| TX EMPTY | SCIFLR   | 11  | 1                                    |
| TXRDY    | SCIFLR   | 8   | 1                                    |

<sup>(1)</sup> The flags are frozen with their reset value while SW nRESET = 0.

## 26.7.8 SCI Interrupt Vector Offset 0 (SCIINTVECT0)

Figure 26-15 and Table 26-13 illustrate this register.

**Figure 26-15. SCI Interrupt Vector Offset 0 (SCIINTVECT0) [offset = 20h]**

LEGEND: R = Read only; -n = value after reset

**Table 26-13. SCI Interrupt Vector Offset 0 (SCIINTVECT0) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-4 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3-0  | INVECT0  | 0-Fh  | Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag in SCIFLR corresponding to the offset that was read. See Table 26-1 for a list of the interrupts.<br><br><b>Note:</b> The flags for the receive (SCIFLR[9]) and the transmit (SCIFLR[8]) interrupt cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register). |

## 26.7.9 SCI Interrupt Vector Offset 1 (SCIINTVECT1)

Figure 26-16 and Table 26-14 illustrate this register.

**Figure 26-16. SCI Interrupt Vector Offset 1 (SCIINTVECT1) [offset = 24h]**

LEGEND: R = Read only; -n = value after reset

**Table 26-14. SCI Interrupt Vector Offset 1 (SCIINTVECT1) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| R-0      |    | R/W-0 |    |
| 15       |    |       | 0  |
| BAUD     |    |       |    |
| R/W-0    |    |       |    |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 26-16. Baud Rate Selection Register (BRS) Field Descriptions**

| Bit   | Field    | Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|----------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | Reserved | 0          | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 23-0  | BAUD     | 0-FF FFFFh | <p>SCI 24-bit baud selection.</p> <p>The SCI has an internally-generated serial clock determined by the VCLK and the prescalers BAUD in this register. The SCI uses the 24-bit integer prescaler BAUD value of this register to select one of over 16,700,000.</p> <p>The baud rate can be calculated using the following formulas:</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{16(\text{Baud} + 1)} \right) \quad (55)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{\text{Baud} + 1} \right) \quad (56)$ <p>For BAUD = 0,</p> $\text{Asynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{32} \right) \quad (57)$ $\text{Isosynchronous baud value} = \left( \frac{\text{VCLK Frequency}}{2} \right) \quad (58)$ <p><a href="#">Table 26-17</a> contains comparative baud values for different P values, with VCLK = 50 MHz, for asynchronous mode.</p> |

**Table 26-17. Comparative Baud Values (Asynchronous Mode) <sup>(1)(2)</sup>**

| 24-Bit Register Value |        | Baud Selected |        | Percent Error |
|-----------------------|--------|---------------|--------|---------------|
| Decimal               | Hex    | Ideal         | Actual |               |
| 26                    | 00001A | 115200        | 115740 | 0.47          |
| 53                    | 000035 | 57600         | 57870  | 0.47          |
| 80                    | 000050 | 38400         | 38580  | 0.47          |
| 162                   | 0000A2 | 19200         | 19172  | -0.15         |
| 299                   | 00012B | 10400         | 10417  | 0.16          |
| 325                   | 000145 | 9600          | 9586   | -0.15         |
| 399                   | 00018F | 7812.5        | 7812.5 | 0.00          |
| 650                   | 00028A | 4800          | 4800   | 0.00          |
| 15624                 | 003BA0 | 200           | 200    | 0.00          |
| 624999                | 098967 | 5             | 5      | 0.00          |

<sup>(1)</sup> VCLK = 50 MHz

<sup>(2)</sup> Values are in decimal except for column 2.

## 26.7.12 SCI Data Buffers (SCIED, SCIRD, SCITD)

The SCI has three addressable registers in which transmit and receive data is stored.

### 26.7.12.1 Receiver Emulation Data Buffer (SCIED)

The SCIED register is addressed at a location different from SCIRD, but is physically the same register.

Figure 26-19 and Table 26-18 illustrate this register.

**Figure 26-19. Receiver Emulation Data Buffer (SCIED) [offset = 30h]**

LEGEND: R = Read only; -n = value after reset

**Table 26-18. Receiver Emulation Data Buffer (SCIED) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                          |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                               |
| 7-0  | ED       | 0-FFh | Emulator data. Reading SCIED[7:0] does not clear the RXRDY flag, unlike reading SCIRD. This register should be used only by an emulator that must continually read the data buffer without affecting the RXRDY flag. |

### 26.7.12.2 Receiver Data Buffer (SCIRD)

This register provides a location for the receiver data. Figure 26-20 and Table 26-19 illustrate this register.

**NOTE:** When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left-justified format padded with trailing zeros. Therefore, the user software should perform a logical shift on the data by the correct number of positions to make it right justified.

**Figure 26-20. Receiver Data Buffer (SCIRD) [offset = 34h]**

LEGEND: R = Read only; -n = value after reset

**Table 26-19. Receiver Data Buffer (SCIRD) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                     |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                          |
| 7-0  | RD       | 0-FFh | Receiver data. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if SET RX INT is set.<br><b>Note: When the data is read from SCIRD, the RXRDY flag is automatically cleared.</b> |

### 26.7.12.3 Transmit Data Buffer Register (SCITD)

Data to be transmitted is written to the SCITD register. [Figure 26-21](#) and [Table 26-20](#) illustrate this register.

**NOTE:** Data written to the SCITD register that is fewer than eight bits long must be right justified, but it does not need to be padded with leading zeros.

**Figure 26-21. Transmit Data Buffer Register (SCITD) [offset = 38h]**

|          |  |  |  |  |  |  |  |  |       |   |  |  |  |  |  |  |    |

|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                           |
| 2    | TX DIR   | 0<br>1 | Transmit pin direction. This bit determines the data direction on the SCITX pin if it is configured with general-purpose I/O functionality (TX FUNC = 0). See Table 26-23 for the SCITX pin control with this bit and others.<br>SCITX is a general-purpose input pin.<br>SCITX is a general-purpose output pin. |
| 1    | RX DIR   | 0<br>1 | Receive pin direction. This bit determines the data direction on the SCIRX pin if it is configured with general-purpose I/O functionality (RX FUNC = 0). See Table 26-24 for the SCIRX pin control with this bit and others.<br>SCIRX is a general-purpose input pin.<br>SCIRX is a general-purpose output pin.  |
| 0    | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                           |

**Table 26-23. SCITX Pin Control**

| Function                     | TX IN <sup>(1)</sup> | TX OUT | TX FUNC | TX DIR |
|------------------------------|----------------------|--------|---------|--------|
| SCITX                        | X                    | X      | 1       | X      |
| General-purpose input        | X                    | X      | 0       | 0      |
| General-purpose output, high | X                    | 1      | 0       | 1      |
| General-purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> TX IN is a read-only bit. Its value always reflects the level of the SCITX pin.

**Table 26-24. SCIRX Pin Control**

| Function                     | RX IN <sup>(1)</sup> | RX OUT | RX FUNC | RX DIR |
|------------------------------|----------------------|--------|---------|--------|
| SCIRX                        | X                    | X      | 1       | X      |
| General-purpose input        | X                    | X      | 0       | 0      |
| General-purpose output, high | X                    | 1      | 0       | 1      |
| General-purpose output, low  | X                    | 0      | 0       | 1      |

<sup>(1)</sup> RX IN is a read-only bit. Its value always reflects the level of the SCIRX pin.

### 26.7.15 SCI Pin I/O Control Register 2 (SCIPIO2)

Figure 26-24 and Table 26-25 illustrate this register.

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset, Refer to the Terminal Functions in the device datasheet for default pin settings.

**Table 26-31. SCI Pin I/O Control Register 8 (SCIPIO8) Field Descriptions**

| Bit  | Field    | Value | Description                                                            |
|------|----------|-------|------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reads return 0. Writes have no effect.                                 |
| 2    | TX PSL   | 0     | TX pin pull select. This bit selects pull type in the input pin SCITX. |
|      |          | 0     | The SCITX pin is a pull down.                                          |
|      |          | 1     | The SCITX pin is a pull up.                                            |
| 1    | RX PSL   | 0     | RX pin pull select. This bit selects pull type in the input pin SCIRX. |
|      |          | 0     | The SCIRX pin is a pull down.                                          |
|      |          | 1     | The SCIRX pin is a pull up.                                            |
| 0    | Reserved | 0     | Writes have no effect.                                                 |

## 26.7.22 Input/Output Error Enable (IODFTCTRL) Register

Figure 26-31 and Table 26-32 illustrate this register. After the basic SCI module configuration, enable the required Error mode to be created followed by IODFT Key enable.

**NOTE:**

1. All the bits are used in IODFT mode only.
2. Each IODFT are expected to be checked individually.

**Figure 26-31. Input/Output Error Enable Register (IODFTCTRL) [offset = 90h]**

**Table 26-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions**

| Bit   | Field           | Value | Description                                                                                                                                                                                      |
|-------|-----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27 | Reserved        | 0     | Reads return 0. Writes have no effect.                                                                                                                                                           |
| 26    | FEN             | 0     | Frame error enable. This bit is used to create a frame error.                                                                                                                                    |
|       |                 | 1     | No error is created.                                                                                                                                                                             |
|       |                 | 1     | The stop bit received is ANDed with 0 and passed to the stop bit check circuitry.                                                                                                                |
| 25    | PEN             | 0     | Parity error enable. This bit is used to create a parity error.                                                                                                                                  |
|       |                 | 1     | No parity error occurs.                                                                                                                                                                          |
|       |                 | 1     | The parity bit received is toggled so that a parity error occurs.                                                                                                                                |
| 24    | BRKD TENA       | 0     | Break detect error enable. This bit is used to create a BRKDT error.                                                                                                                             |
|       |                 | 1     | No error is created.                                                                                                                                                                             |
|       |                 | 1     | The stop bit of the frame is ANDed with 0 and passed to the RSM so that a frame error occurs. Then the RX pin is forced to continuous low for 10 T <sub>BITS</sub> so that a BRKDT error occurs. |
| 32-21 | Reserved        | 0     | Reads return 0. Writes have no effect.                                                                                                                                                           |
| 20-19 | PIN SAMPLE MASK | 0     | Pin sample mask. These bits define the sample number at which the TX pin value that is being transmitted will be inverted to verify the receive pin samples majority detection circuitry.        |
|       |                 | 0     | No mask is used.                                                                                                                                                                                 |
|       |                 | 1h    | Invert the TX Pin value at 7th.SCLK.                                                                                                                                                             |
|       |                 | 2h    | Invert the TX Pin value at 8th.SCLK.                                                                                                                                                             |
|       |                 | 3h    | Invert the TX Pin value at 9th.SCLK.                                                                                                                                                             |

**Table 26-32. Input/Output Error Enable Register (IODFTCTRL) Field Descriptions (continued)**

| Bit   | Field    | Value      | Description                                                                                                                                                                                                                                                  |
|-------|----------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18-16 | TX SHIFT |            | Transmit shift. These bits define the amount by which the value on TX pin is delayed so that the value on the RX pin is asynchronous. This feature is not applicable to the start bit.                                                                       |
|       |          | 0          | No delay occurs.                                                                                                                                                                                                                                             |
|       |          | 1h         | The value is delayed by 1 SCLK.                                                                                                                                                                                                                              |
|       |          | 2h         | The value is delayed by 2 SCLK.                                                                                                                                                                                                                              |
|       |          | 3h         | The value is delayed by 3 SCLK.                                                                                                                                                                                                                              |
|       |          | 4h         | The value is delayed by 4 SCLK.                                                                                                                                                                                                                              |
|       |          | 5h         | The value is delayed by 5 SCLK.                                                                                                                                                                                                                              |
|       |          | 6h         | The value is delayed by 6 SCLK.                                                                                                                                                                                                                              |
|       |          | 7h         | No delay occurs.                                                                                                                                                                                                                                             |
| 15-12 | Reserved | 0          | Reads return 0. Writes have no effect.                                                                                                                                                                                                                       |
| 11-8  | IODFTENA |            | IODFT enable key. Write access permitted in Privilege mode only.                                                                                                                                                                                             |
|       |          | Ah         | IODFT is enabled.                                                                                                                                                                                                                                            |
|       |          | All Others | IODFT is disabled.                                                                                                                                                                                                                                           |

| 0     | RXPENA   |            | Module analog loopback through receive pin enable. Write access permitted in Privilege mode only.<br>This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path (in analog loopback mode).          |
|       |          | 0          | Analog loopback through the transmit pin is enabled.                                                                                                                                                                                                         |
|       |          | 1          | Analog loopback through the receive pin is enabled.                                                                                                                                                                                                          |

## 26.8 GPIO Functionality

The following sections apply to all device pins that can be configured as functional or general-purpose I/O pins.

### 26.8.1 GPIO Functionality

Figure 26-32 illustrates the GPIO functionality.

**Figure 26-32. GPIO Functionality**

### 26.8.2 Under Reset

The following apply if a device is under reset:

- Pull control. The reset pull control on the pins is enabled.
- Input buffer. The input buffer is enabled.
- Output buffer. The output buffer is disabled.

### 26.8.3 Out of Reset

The following apply if the device is out of reset:

- Pull control. The pull control is enabled by clearing the PD (pull control disable) bit in the SCIP107 register (Section 26.7.20). In this case, if the PSL (pull select) bit in the SCIP108 register (Section 26.7.21) is set, the pin will have a pull-up. If the PSL bit is cleared, the pin will have a pull-down. If the PD bit is set in the control register, there is no pull-up or pull-down on the pin.
- Input buffer. The input buffer is always enabled in functional mode.

---

**NOTE:** The pull-disable logic depends on the pin direction. It is independent of whether the device is in I/O or functional mode. If the pin is configured as output or transmit, then the pulls are disabled automatically. If the pin is configured as input or receive, the pulls are enabled or disabled depending on bit PD in the pull disable register SCIP107 (Section 26.7.20).

---

- Output buffer. A pin can be driven as an output pin if the TX DIR bit is set in the pin direction control register (SCIP101; Section 26.7.14) AND the open-drain feature is not enabled in the SCIP106 register (Section 26.7.19).

### 26.8.4 Open-Drain Feature Enabled on a Pin

The following apply if the open-drain feature is enabled on a pin:

- The output buffer is enabled, if a low signal is being driven on to the pin.
- The output buffer is disabled (the direction control signal DIR is internally forced low), if a high signal is being driven on to the pin.

---

**NOTE:** The open-drain feature is available only in I/O mode (SCIP100; Section 26.7.13).

---

### 26.8.5 Summary

The behavior of the input buffer, output buffer, and the pull control is summarized in Table 26-33.

**Table 26-33. Input Buffer, Output Buffer, and Pull Control Behavior as GPIO Pins**

| Device under Reset? | Pin Direction (DIR) <sup>(1)(2)</sup> | Pull Disable (PULDIS) <sup>(1)(3)</sup> | Pull Select (PULSEL) <sup>(1)(4)</sup> | Pull Control | Output Buffer | Input Buffer |
|---------------------|---------------------------------------|-----------------------------------------|----------------------------------------|--------------|---------------|--------------|
| Yes                 | X                                     | X                                       | X                                      | Enabled      | Disabled      | Enabled      |
| No                  | 0                                     | 0                                       | 0                                      | Pull down    | Disabled      | Enabled      |
| No                  | 0                                     | 0                                       | 1                                      | Pull up      | Disabled      | Enabled      |
| No                  | 0                                     | 1                                       | 0                                      | Disabled     | Disabled      | Enabled      |
| No                  | 0                                     | 1                                       | 1                                      | Disabled     | Disabled      | Enabled      |
| No                  | 1                                     | X                                       | X                                      | Disabled     | Enabled       | Enabled      |

<sup>(1)</sup> X = Don't care

<sup>(2)</sup> DIR = 0 for input, = 1 for output

<sup>(3)</sup> PULDIS = 0 for enabling pull control  
= 1 for disabling pull control

<sup>(4)</sup> PULSEL = 0 for pull-down functionality  
= 1 for pull-up functionality

## ***Inter-Integrated Circuit (I2C) Module***

This chapter describes the inter-integrated circuit (I2C or I<sup>2</sup>C) module. The I2C is a multi-master communication module providing an interface between the Texas Instruments (TI) microcontroller and devices compliant with Philips Semiconductor I<sup>2</sup>C-bus specification version 2.1 and connected by an I2C-bus. This module will support any slave or master I2C compatible device.

## 27.1 Overview

The I2C has the following features:

- Compliance to the Philips I<sup>2</sup>C bus specification, v2.1 (*The I2C Specification*, Philips document number 9398 393 40011)
  - Bit/Byte format transfer
  - 7-bit and 10-bit device addressing modes
  - General call
  - START byte
  - Multi-master transmitter/ slave receiver mode
  - Multi-master receiver/ slave transmitter mode
  - Combined master transmit/receive and receive/transmit mode
  - Transfer rates of 10 kbps up to 400 kbps (Phillips fast-mode rate)
- Free data format
- Two DMA events (transmit and receive)
- DMA event enable/disable capability
- Seven interrupts that can be used by the CPU
- Operates with VBUS frequency from 6.7 MHz up
- Operates with module frequency between 6.7 MHz to 13.3 MHz
- Module enable/disable capability
- The SDA and SCL are optionally configurable as general purpose I/O
- Slew rate control of the outputs
- Open drain control of the outputs
- Programmable pullup/pulldown capability on the inputs
- Supports Ignore NACK mode

**NOTE:** This I2C module does **not** support:

- High-speed (HS) mode
- C-bus compatibility mode
- The combined format in 10-bit address mode (the I2C sends the slave address second byte every time it sends the slave address first byte)

### 27.1.1 Introduction to the I2C Module

The I2C module supports any slave or master I2C-compatible device. [Figure 27-1](#) shows an example of multiple I2C serial ports connected for a two-way transfer from one device to another device.

**Figure 27-1. Multiple I2C Modules Connection Diagram**

### 27.1.2 Functional Overview

The I2C module is a serial bus that supports multiple master devices. In multimaster mode, one or more devices can be connected to the same bus and are capable of controlling the bus. Each I2C device on the bus is recognized by a unique address and can operate as either a transmitter or a receiver, depending on the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered a master or a slave when performing data transfers.

---

**NOTE:** A master device is the device that initiates the data transfer on a bus and generates the clock signal that permits the transfer. During the transmission, any device addressed by the master is considered the slave.

---

Data is communicated to devices interfacing to the I2C module using the serial data pin (SDA) and the serial clock pin (SCL) as shown in [Figure 27-2](#). These two wires carry information between the device and the other devices connected to the I2C bus. Both SDA and SCL pins on the device are bidirectional. They must be connected to a positive supply voltage through a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the wired-AND function.

The device has a special mode that can be entered to ignore a NACK generated from non-compliant I2C devices that are incapable of generating an ACK.

The I2C module consists of the following primary blocks:

- A serial Interface: one data pin (SDA) and one clock pin (SCL)
- The device register interface
  - Data registers to temporarily hold received data and transmitted data traveling between the SDA pin and the CPU or the DMA
  - Control and status registers
- A prescaler to divide down the input clock that is driven to the I2C module
- A peripheral bus interface to enable the CPU and DMA to access the I2C module registers
- An arbitrator to handle arbitration between the I2C module (when configured as a master) and another master
- Interrupt generation logic (interrupts can be sent to the CPU)
- A clock synchronizer that synchronizes the I2C input clock (from the system module) and the clock on the SCL pin, and synchronizes data transfers with masters of different clock speeds
- A noise filter on each of the two serial pins
- DMA event generation logic that synchronizes data reception and data transmission in the I2C module for DMA transmission

In [Figure 27-2](#), the CPU or the DMA writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

When the I2C function is not needed, the pins may be controlled as general-purpose input/output (GPIO) pins. The I/O structure of each pin includes:

- programmable slew rate control of the outputs
- open drain mode
- programmable pull enable/disable on the input
- programmable pull up/pull down function on the input

The diagram illustrates the internal architecture of the I2C peripheral. It features a central **State Machine** block that coordinates the communication. Key components and their connections include:

- Registers and Control:**
  - I2CSEL, I2CSRS, I2CPDIS, I2CPDR, I2CPDIR:** These registers are connected to a multiplexer that selects the data for the **SDA** output line.
  - I2CSET, I2CDCLR:** These registers are connected to the **VBUS** line for configuration and clearing operations.
  - I2COUT, I2CDOUT:** These registers are connected to the **VBUS** line for output data.
  - I2CIN, I2CDIN:** These registers are connected to the **VBUS** line for input data.
  - I2CSET, I2CDSET:** These registers are connected to the **VBUS** line for setting operations.
  - I2CCLR, I2CDCLR:** These registers are connected to the **VBUS** line for clearing operations.
  - I2CSET, I2CDSET:** These registers are connected to the **VBUS** line for setting operations.
  - I2CCLR, I2CDCLR:** These registers are connected to the **VBUS** line for clearing operations.
- Signal Processing:**
  - Noise Filter:** Two noise filters are present, one for the **SDA** line and one for the **SCL** line, to ensure signal integrity.
  - Arbitrator:** This block manages the arbitration process on the **SCL** line to prevent collisions.
  - Clock synchronizer:** This block synchronizes the **SCL** clock signal with the internal system clock.
- Internal State and Timing:**
  - State Machine:** The central control unit that manages the overall I2C protocol sequence.
  - Clock generator:** Generates the internal clock signal for the peripheral.
  - I2CCNT, I2CMDR, I2CEMDR, I2CSAR:** Registers for counting, command, error, and address management.
  - I2CCKH, I2CCKL:** Registers for clock high and low period control.
  - I2CPCSC:** Register for period control.
  - I2COAR, I2CIVR, I2CSTR:** Registers for address, interrupt, and status management.
- Interrupts and DMA:**
  - I2CISR:** Interrupt Status Register, which triggers an **Interrupt to VIM** when a specific event occurs.
  - I2CDMACR:** DMA Control Register, which enables **TX DMA REQ** and **RX DMA REQ** for data transfer.

### 27.1.3 Clock Generation

As shown in Figure 27-3, the I2C module uses the input clock generated from the device clock generator to generate the module clock and master clock. The I2C input clock is the device peripheral clock (VBUS\_CLK). The clock is then divided twice more inside the I2C module to produce the module clock and the master clock.

**Figure 27-3. Clocking Diagram for the I2C Module**

The module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the input clock to produce the module clock. To specify the divide-down value, initialize the I2CPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{ModuleClockFrequency} = \frac{\text{I2CInputClockFrequency}}{(\text{I2CPSC} + 1)} \quad (59)$$

The module clock frequency must be between 6.7MHz and 13.3MHz. The prescaler can only be initialized while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the I2CPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of the communication between the I2C module and a slave. As shown in Figure 27-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the I2CCKL to divide down the low portion of the module clock signal and uses the I2CCKH to divide down the high portion of the module clock signal.

The resulting frequency is:

$$\text{MasterClockFrequency} = \frac{\text{ModuleClockFrequency}}{(\text{I2CCKL} + d) + (\text{I2CCKH} + d)} \quad (60)$$

$$\text{MasterClockFrequency} = \frac{\text{I2CInputClockFrequency}}{(\text{I2CPSC} + 1)((\text{I2CCKL} + d) + (\text{I2CCKH} + d))} \quad (61)$$

where  $d$  depends on the value of I2CPSC:

| I2CPSC         | $d$ |
|----------------|-----|
| 0              | 7   |
| 1              | 6   |
| Greater than 1 | 5   |

**NOTE:** The master clock frequency defined above does not include rise/fall time and latency of the synchronizer inside the module. The actual transfer rate will be slower than the value calculated from the formula above. Also, due to the nature of SCL synchronization, the SCL clock period could change if SCL synchronization is taking place.

## 27.2 I2C Module Operation

The following section discusses how the I2C module operates.

### 27.2.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Because of a variety of different technology devices that can be connected to the I2C-bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{CCIO}$ . For details, see the device specific data sheet.

### 27.2.2 I2C Module Reset Conditions

The I2C module can be reset in the following two ways:

- Through the global peripheral reset. A device reset causes a global peripheral reset.
- By clearing the  $\overline{IRS}$  bit in the I2C mode register (I2CMODR). When the global peripheral reset is removed, the  $\overline{IRS}$  bit is cleared to 0, keeping the I2C module in the reset state.

### 27.2.3 I2C Module Data Validity

The data on the SDA must be stable during the high period of the clock. See [Figure 27-4](#). The high and low state of the data line, the SDA, can only change when the clock signal is low.

**Figure 27-4. Bit Transfer on the I2C Bus**

### 27.2.4 I2C Module Start and Stop Conditions

START and STOP conditions are generated by a master I2C module.

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of data transfer. The bus is considered to be busy after the START condition, and the bus busy bit (BB) in I2CSR is set to 1.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of data transfer. The bus is considered to be free after the STOP condition, therefore the BB bit in I2CSR is cleared to 0.

**Figure 27-5. I2C Module START and STOP Conditions**

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in the I2CMDR must both be set to 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated.

### 27.2.5 Serial Data Formats

The I2C module operates in byte data format. Each message put on the SDA line is 2 to 8-bits long. The number of messages that can be transmitted or received is unrestricted. The data is transferred with the most significant bit (MSB) first (Figure 27-6). Each message is followed by an acknowledge bit from the I2C if it is in receiver mode. The I2C module does not support little endian systems.

**Figure 27-6. I2C Module Data Transfer**

The first byte after a START condition (S) always consists of 8 bits that comprise either a 7-bit address plus the R/W bit, or 8 data bits. The eighth bit, R/W, in the first byte determines the direction of the data. When the R/W bit is 0, the master writes (transmits) data to a selected slave device; when the R/W bit is 1, the master reads (receives) data from the slave device. In acknowledge mode, an extra bit dedicated for the acknowledgement (ACK) bit is inserted after each message.

The I2C module supports the following formats:

- 7-bit addressing format (Figure 27-7)
- 10-bit addressing format (Figure 27-8)
- 7-bit/10-bit addressing format with repeated START condition (Figure 27-9)
- Free-data format (Figure 27-10)

### 27.2.5.1 7-Bit Addressing Format

In the 7-bit addressing format (Figure 27-7), the first byte after the START condition consists of a 7-bit slave address followed by the  $R/\overline{W}$  bit (in the LSB). The  $R/\overline{W}$  bit determines the direction of the data transfer:

- $R/\overline{W} = 0$ : The master writes (transmits) data to the addressed slave.
- $R/\overline{W} = 1$ : The master reads (receives) data from the slave.

An extra clock cycle dedicated for acknowledgement (ACK) is inserted after each byte. If the ACK is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the  $R/\overline{W}$  bit). The device I2C allows n to be a number between 2 to 8, programmable by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

To select the 7-bit addressing format, write 0 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

**Figure 27-7. I2C Module 7-Bit Addressing Format**

### 27.2.5.2 10-Bit Addressing Format

The 10-bit addressing format is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. In the 10-bit addressing format (Figure 27-8), the first byte is 11110b, the two MSBs of the 10-bit slave address, and the  $R/\overline{W}$  bit. The ACK bit is inserted after each byte. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send an acknowledgement after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use repeated a START condition to change the data direction.

To select the 10-bit addressing format, write 1 to the expanded address enable (XA) bit of I2CMDR and make sure the free data format mode is off (FDF = 0 in I2CMDR).

**Figure 27-8. I2C Module 10-bit Addressing Format**

### 27.2.5.3 Using the Repeated START Condition

At the end of each byte, the master can drive another START condition (Figure 27-9). Using this capability, a master can transmit/receive any number of data bytes before generating a STOP condition. The length of a data byte can be from 2 to 8 bits. The repeated START condition can be used with the 7-bit addressing, 10-bit addressing, or the free data formats.

**Figure 27-9. I2C Module 7-Bit Addressing Format with Repeated START**

#### 27.2.5.4 Free Data Format

In this format (Figure 27-10), the first byte after a START condition is a data byte. The ACK bit is inserted after each byte, followed by another 8 bits of data. No address or data direction bit is sent. Therefore, the transmitter and receiver must both support the free data format. The direction of data transmission (transmit or receive) remains constant throughout the transfer.

To select the free data format, write a 1 to the free data format (FDF) bit of the I2CMDR. The free data format is not supported in the digital loop back mode.

**Figure 27-10. I2C Module in Free Data Format**

#### 27.2.6 NACK Bit Generation

When the I2C module is a receiver (master or slave), it can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 27-1 summarizes the various ways a NACK can be generated.

**Table 27-1. Ways to Generate a NACK Bit**

| I2C Module Condition                               | Basic NACK Bit Generation Options                                                                                                                                                       | Additional Option                                                                      |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Slave receiver mode                                | Disable data transfers (STT = 0)<br>Allow an overrun condition (RSFULL = 1)<br>Reset the module (IRS = 0)                                                                               | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |
| Master receiver mode and repeat mode (RM = 1)      | Generate a STOP condition (STP = 1)<br>Reset the module (IRS = 0)                                                                                                                       | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |
| Master receiver mode with non-repeat mode (RM = 0) | If STP = 1, allow the internal data counter to count down to 0 and thus force a STOP condition.<br>If STP = 0, make STP = 1 to generate a STOP condition.<br>Reset the module (IRS = 0) | Set the NACKMOD bit before the rising edge of the last data bit you intend to receive. |

In some applications, the slave cannot generate the ACK signal. If the IGNACK bit is set in the I2CEMDR register, the resulting NACK will be ignored and the I2C block will continue the data transfer.

## 27.3 I2C Operation Modes

### 27.3.1 Master Transmitter Mode

All masters begin in this mode. The I2C module is a master and transmits control information and data to a slave. In this mode, data assembled in any of the addressing formats shown in [Figure 27-7](#), [Figure 27-8](#), or [Figure 27-9](#) is shifted out onto the SDA pin and synchronized with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL pin is held low when the intervention of the device is required ( $\overline{XSMT} = 0$ ) after a byte has been transmitted.

---

**NOTE:** If the I2C is configured for two simultaneous master transmissions, wait until the MST and BB have been reset before performing the second master transmission.

---

Failure to wait for the MST and BB to reset will prevent the start condition on the second transfer from being issued and the bus BB will not be set. Typically the end of the first transfer is handled by polling BB. However, the MST bit is not reset at the same instant as the BB bit. As a result, when the second master transmission is initiated before the resetting of the MST, the MST bit for the second transfer is reset. This prevents the I2C from recognizing itself as the master, thus failing to occupy the bus.

### 27.3.2 Master Receiver Mode

In this mode, the I2C module is a master and receives data from a slave. This mode can only be entered from the master transmitter mode (the I2C module must first transmit a command to the slave). In any of the addressing formats shown in [Figure 27-7](#), [Figure 27-8](#), or [Figure 27-9](#), the master receiver mode is entered after the slave address byte and the R/W bit have been transmitted (if the R/W bit is 1). Serial data bits received on the SDA pin are shifted in with the self-generated clock pulses on the SCL pin. The clock pulses are inhibited and the SCL is held low when the intervention of the device is required ( $RSFULL = 1$ ) after a byte has been received. At the end of the transfer, the master-receiver signals the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter then releases the data line allowing the master-receiver to generate a STOP condition or a repeated START condition.

In many applications, the size of the message is in the initial bytes of the message itself. Since the size of the message is not known to the master before the transmission/reception starts, the master must use the repeat mode in order to force the stop condition when the reception is completed. The repeat mode is enabled by setting the RM bit to 1. Due to the double buffer implementation on the receive side, the master must generate the stop condition ( $STP = 1$ ) after reading the (message size - 1)<sup>th</sup> data.

### 27.3.3 Slave Transmitter Mode

In this mode, the I2C module is a slave and transmits data to a master. This mode can only be entered from the slave receiver mode (The I2C module must first receive a command from the master). In any of the addressing formats shown in [Figure 27-7](#), [Figure 27-8](#), or [Figure 27-9](#), the slave transmitter mode is entered if the slave address byte is the same as its own address and the R/W bit has been transmitted (if the R/W bit is set to 1). The slave transmitter shifts the serial data out on the SDA pin with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low when intervention of the device is required ( $\overline{XSMT} = 0$ ) after a byte has been transmitted.

### 27.3.4 Slave Receiver Mode

In this mode, the I2C module is a slave and receives data from a master. All slaves begin in this mode. Serial data bits received on the SDA pin are shifted in with the clock pulses that are generated by the master device. The slave device does not generate the clock, but it can hold the SCL pin low while intervention of the device is required ( $RSFULL = 1$ ) after a byte has been received.

### 27.3.5 Low Power Mode

The I2C module can be placed in low-power mode by a global low-power mode initiated by the system (by writing to the Peripheral Power-Down Set Register in the Peripheral Central Resource (PCR) module).

In effect, low-power mode shuts down all the clocks to the module. In global low-power mode, no registers are visible to the software; nothing can be written to or read from any register.

### 27.3.6 Free Run Mode

The I2C module can be placed in free run mode when the FREE bit (I2CMDR.14) is set to 1. This bit is primarily used on an emulator when encountering a breakpoint while debugging software. When the FREE bit is set to 0, the I2C responds differently depending on whether the SCL is high or low. If the SCL is low, the I2C stops immediately and keeps driving the SCL low whether the I2C is the master transmitter or receiver. If the SCL is high, the I2C waits until the SCL becomes a low and then stops. If the I2C is a slave, it stops when the transmission/reception completes.

### 27.3.7 Ignore NACK Mode

The I2C module can be placed in the ignore NACK mode by setting the IGNACK bit in the I2CEMDR register. This mode allows an I2C module that is configured as a master transmitter to ignore a NACK from a slave device that is not capable of generating a proper ACK signal.

## 27.4 I2C Module Integrity

The following section discusses how the I2C module maintains priorities and order among signals and commands.

### 27.4.1 Arbitration

If two or more master transmitters simultaneously start a transmission on the same bus, an arbitration procedure is invoked. [Figure 27-11](#) illustrates the arbitration procedure between two devices. The arbitration procedure uses the data presented on the SDA bus by the competing transmitters. The first master transmitter that generates a high is overruled by the other master that generates a low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. The master transmitter that loses the arbitration switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration-lost interrupt. The data transmitted by the other master module is salvaged, and the I2C continues to receive data from the master module. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If, during a serial transfer, the arbitration procedure is still in progress when a repeated START condition or STOP condition is transmitted to I2C bus, the master transmitters involved must send the repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Slaves are not involved in the arbitration procedure.

**Figure 27-11. Arbitration Procedure Between Two Master Transmitters**

### 27.4.2 I2C Clock Generation and Synchronization

Under normal conditions only one master device generates the clock signal; the SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. Figure 27-12 illustrates clock synchronization. The wired-AND property of the SCL line means that a device that first generates a low period on the SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start their own low period. The SCL line is held low by the device with the longest low period. The other devices that finish their low periods must wait for the SCL line to be released before starting their high periods. A synchronized signal on the SCL is obtained where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

#### NOTE: I2C Protocol Fault

The following conditions violate the clock spec as defined in the Philips I<sup>2</sup>C bus specification, v2.1 (*The I2C Specification*, Philips document number 9398 393 40011), and will result in an I2C protocol fault:  $I2CCLKH = 2$   $I2CCLKL = 2I2CPSC = 2$ . This will cause the SDA data transition to occur while the SCL is high.

**Figure 27-12. Synchronization of Two I2C Clock Generators During Arbitration**

### 27.4.3 Prescaler

The I2C module is operated by the module clock. This clock is generated by way of the I2C prescaler block. The prescaler block consists of a 8-bit register, I2CPSC, used for dividing down the device peripheral clock (VBUS\_CLK) to obtain a module clock between 6.7 MHz and 13.3 MHz.

### 27.4.4 Noise Filter

The noise filter is used to suppress any noises that are 50ns or less. It is designed to suppress noise with one module clock, assuming the lower and upper limits of the module clock are 6.7MHz and 13.3MHz, respectively.

## 27.5 Operational Information

The following section provides specific information about how the I2C module operates.

### 27.5.1 I2C Module Interrupts

The I2C module generates seven types of interrupts. These seven interrupts are accompanied with seven interrupt mask bits in the interrupt mask register (I2CIMR) and with seven interrupt flag bits in the status register (I2CSR).

#### 27.5.1.1 I2C Interrupt Requests

The I2C module generates the interrupt requests described below. All requests are multiplexed through an arbiter into a single I2C interrupt request to the CPU. Each interrupt request has a flag bit and an enable bit. Interrupts must be enabled prior to the occurrence of the expected interrupt condition. When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the interrupt request is forwarded to the CPU as an I2C interrupt request. As an alternative, the CPU can poll all of the bits shown in [Table 27-2](#).

**Table 27-2. Interrupt Requests Generated by I2C Module**

| Flag  | Name                            | Generated                                                                                                                                                                                                                                    |
|-------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AL    | Arbitration-lost interrupt      | Generated when the I2C module has lost an arbitration contest with another master-transmitter                                                                                                                                                |
| NACK  | No-acknowledge interrupt        | Generated when the master I2C does not receive an acknowledge from the receiver                                                                                                                                                              |
| ARDY  | Register-access-ready interrupt | Generated when the previously programmed address, data and command have been performed and the status bits have been updated. The interrupt is used to notify the device that the I2C registers are ready to be accessed.                    |
| RXRDY | Receive-data-ready interrupt    | Generated when the received data in the receive-shift register (I2CSR) has been copied into the data receive register (I2CDRR). The RXRDY bit can also be polled by the device to determine when to read the received data in the I2CDRR.    |
| TXRDY | Transmit-data-ready interrupt   | Generated when the transmitted data has been copied from the data transmit register (I2CDXR) into the transmit-shift register (I2CXSR). The TXRDY bit can also be polled by the device to determine when to write the next data into I2CDXR. |
| SCD   | Stop-condition-detect interrupt | Generated when a STOP condition has been detected.                                                                                                                                                                                           |
| AAS   | Address-as-slave interrupt      | Generated when the I2C has recognized its own slave address or an address of all zeroes.                                                                                                                                                     |

The interrupt vector register (I2CIVR) contains the binary-coded-interrupt vector that indicates the highest priority interrupt that is pending and enabled. When I2CIVR is read, the corresponding interrupt flags for AL, NACK and SCD are automatically cleared, if their interrupts are enabled. Reading the I2CIVR will not clear the AAS, ARDY, RXRDY, or TXRDY interrupt pending flags. Please see [Section 27.6.3](#) for the method to clear these four flags.

If more than one interrupt is pending, a new interrupt will be generated for the next highest priority pending interrupt when you re-enable the I2C interrupt.

A transmit interrupt is generated just after the START condition in master transmitter mode. This ensures that the CPU will get an interrupt even if no slave returns an ACK to the slave address following the START condition.

It is important to note that when the I2C is configured to generate interrupts as a slave transmitter and the backward compatibility mode (BCM) bit is set to 1, an extra transmit interrupt occurs. The application should monitor the ACK from the master to determine whether to load another byte into I2CDXR.

### 27.5.2 DMA Controller Events

The I2C module has two events that use the DMA controller to synchronously read received data (I2CREVNT) from I2CDRR, and synchronously write data (I2CWEVNT) to the transmit buffer, I2CDXR. The read and write events have the same timing as I2CRRDY (I2CRINT) and I2CXRDY (I2CXINT), respectively.

The CPU or the DMA controller reads the received data from I2CDRR and writes the data to be transmitted to I2CDXR. The RXRDY bit is automatically cleared when the DMA controller reads the I2CDRR register, and the TXRDY bit is automatically cleared when the DMA controller writes to the I2CDXR register.

Data written to I2CDXR is copied to I2CXSR and shifted out from the SDA pin when the I2C module is configured as a transmitter. When the I2C module is configured as a receiver, received data is shifted into ICRSR and copied to I2CDRR, which can be read by the CPU or the DMA controller.

A transmit event (I2CWEVNT) is generated after a START condition in master transmitter mode. This ensures that the DMA gets an event even if no slave returns an ACK to the slave address following the START condition.

---

**NOTE: Unexpected DMA transmit and receive event**

An unexpected DMA transmit event (ICXEVT) and a DMA receive event (ICXRDY) are generated in 10-bit, master transmit, repeat mode. This event occurs soon after the start condition but before the first bit of the address is transmitted. In this event, no DMA activity should be initiated without the slave ACK being received.

---

### 27.5.3 I2C Enable/Disable

The I2C module can be enabled or disabled with the I2C reset enable bit (IRS) in the I2C module register (I2CMDR). This occurs in one of two ways:

- Write 0 to the I2C reset bit (IRS) in I2CMDR. All status bits are forced to the default values and the I2C mode remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high impedance state.
- Initiate a device reset by driving the  $\overline{\text{PORRST}}$  pin low. The entire device is reset and is held in the reset state until the pin is released and is driven high. When  $\overline{\text{PORRST}}$  is released, all I2C module registers are reset to their default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until a 1 is written to the IRS bit.

IRS must be 0 while the I2C module is being configured. Forcing IRS to 0 can be used to save power and also clear error conditions.

### 27.5.4 General Purpose I/O

Both of the I2C pins can be programmed to be general-purpose I/O pins via the I2C pin control registers (I2CPFNC, I2CDIR, I2CDOOUT, and I2CDIN).

When the I2C module is not used, the I2C pins may be programmed to be either general purpose input or general-purpose output pins. This function is controlled in the I2CDIR and I2CPFNC registers. Note that each pin can be programmed to be either an I2C pin or a GIO pin.

If the I2C function is to be used, the application software must ensure that each pin is configured as an I2C pin and not a GIO pin, or else unexpected behavior may result.

### 27.5.5 Pull Up/Pull Down Function

I2C module pins can have either an active pull up or active pull down that makes it possible to leave the pins unconnected externally. The pins can be programmed to have the active pull function enabled or disabled by writing to the corresponding bit in the I2CPDIS register. Please see the device-specific data sheet for the default internal pull (pull-up, pull-down or no pull) on the pins.

The pull on the pins is programmable to a setting other than the default internal pull as specified in the data sheet. The pins can be programmed to have either an active pull up or an active pull down function by writing to the corresponding bit in I2CPSEL register. The pull up/pull down function is active on the pin only when the pull enabled is programmed in the I2CPDIS register.

The pull up/pull down functions are deactivated when a bidirectional pin is configured as an output. At system reset, the pull up function of all the pins is enabled. Please see the device-specific data sheet for the current supplied by the pull up/pull down.

### 27.5.6 Open Drain Function

The I2C pins can be programmed to include an open drain function when they are configured as output pins. This is done by writing to the corresponding bit of the I2CPDR register. When the open drain function is enabled, a low value (0) written to the data output register forces the pin to a low output voltage ( $V_{OL}$  or lower), whereas a high value (1) written to the data output register forces the pin to a high-impedance state. The open drain function is disabled when the pin is configured as an input pin.

## 27.6 I2C Control Registers

[Table 27-3](#) provides a summary of the control registers. The upper word (upper 16 bits) of the registers all read as 0s. Writes have no effect on these bits. The base address for the control registers is FFF7 D400h.

**Table 27-3. I2C Control Registers**

| Offset  | Acronym  | Register Description               | Section                         |
|---------|----------|------------------------------------|---------------------------------|
| 00h     | I2COAR   | I2C Own Address Manager            | <a href="#">Section 27.6.1</a>  |
| 04h     | I2CIMR   | I2C Interrupt Mask Register        | <a href="#">Section 27.6.2</a>  |

### 27.6.1 I2C Own Address Manager (I2COAR)

The 16-bit memory-mapped I2C own address register is used to specify its own address. [Figure 27-13](#) and [Table 27-4](#) describe this register.

**Figure 27-13. I2C Own Address Manager Register (I2COAR) [offset = 00h]**

| 9-0   | OA       | 0-3FFh | Own address<br>These bits reflect the bus address of the I2C module. When the expand address (XA) bit I2CMDR.8 is set to 1, the I2C is in expand address mode (10-bit addressing mode). In either 7 or 10-bit address mode, all 10-bits are both readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. <a href="#">Table 27-5</a> provides the correct modes for these bits. Note that the user can program the I2C own address to any value as long as it does not conflict with other components in the system. |

**Table 27-5. Correct Mode for OA Bits**

| Bits Used | Mode              | Value of XA |
|-----------|-------------------|-------------|
| OA.6:0    | 7 Bit Addressing  | 0           |
| OA.9:0    | 10 Bit Addressing | 1           |

## 27.6.2 I2C Interrupt Mask Register (I2CIMR)

The 7-bit memory-mapped I2C interrupt mask register is used by the device to enable/disable the interrupts. [Figure 27-14](#) and [Table 27-6](#) describe this register.

**Figure 27-14. I2C Interrupt Mask Register (I2CIMR) [offset = 04h]**

| 12  | BB       |       | Bus busy<br>This bit indicates the state of the serial bus.<br>On reception of a START condition or if the I2C detects a low state on I2CSCL, the device sets BB = 1. If the nIRS is set to 1 during transaction between other I2C devices, the BB bit is set at the first falling edge of SCL or START condition.<br>BB is cleared to 0 after the reception of a STOP condition. BB is kept to 0 regardless of the SCL state when the I2C is in reset (nIRS = 0).                                                                                                                                                                                                                                                         |
|     |          | 0     | The bus is free.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|     |          | 1     | The bus is busy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 11  | RSFULL   |       | Receiver shift full<br>This bit is set to 1 to indicate that the receiver has experienced overrun. Overrun occurs when the receive shift register is full and I2CDRR has not been read since the receive shift register to I2CDRR transfer. The contents of I2CDRR are not lost. The I2C core logic is holding for I2CDRR read access. This bit is also set when, in master-repeat-mode, the I2C receives a byte of data. There is no difference between RXRDY and RSFULL in this case. The I2C master will not continue the transfer as long as the received data is in the I2CDRR or receive shift register.<br><b>RSFULL is cleared when reading the I2CDRR, resetting the I2C (nIRS = 0), or resetting the device.</b> |
|     |          | 0     | No overrun has occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|     |          | 1     | An overrun has occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|     |       | 0     | No loss of arbitration has been detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|     |       | 1     | The device in the master transmitter mode senses it has lost an arbitration. This occurs when two or more transmitters start a transmission almost simultaneously or when the I2C attempts to start a transfer while BB=1. When this is set to 1 due to arbitration lost, the device becomes a slave receiver and the MST, STT, and STP bits in I2CMDR are cleared to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 27.6.4 I2C Clock Divider Low Register (I2CCKL)

The I2C clock divider low register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock low time. [Figure 27-16](#) and [Table 27-8](#) describe this register.

**Figure 27-16. I2C Clock Divider Low Register (I2CCKL) [offset = 0Ch]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-8. I2C Clock Divider Low Register (I2CCKL) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CLKL  | 0-FFFFh | <p>Low time clock division factor</p> <p>Used to divide down the module clock to create the low time portion of the master clock signal that will appear on the SCL pin.:</p> $LowTime = \left( \frac{I2CCKL + d}{ModuleClockFrequency} \right) \quad (62)$ <p>where <i>d</i> is the value that depends on the I2CPSC (see <a href="#">Section 27.1.3</a>).</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p> |

### 27.6.5 I2C Clock Control High Register (I2CCKH)

The I2C clock divider high register is a 16-bit memory-mapped register used to divide the master clock down to obtain the I2C serial clock high time. [Figure 27-17](#) and [Table 27-9](#) describe this register.

**Figure 27-17. I2C Clock Control High Register (I2CCKH) [offset = 10h]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-9. I2C Clock Control High Register (I2CCKH) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CLKH  | 0-FFFFh | <p>High time clock division factor</p> <p>Used to divide down the module clock to create the high time portion of the master clock signal that will appear on the SCL pin:</p> $HighTime = \left( \frac{I2CCKH + d}{ModuleClockFrequency} \right) \quad (63)$ <p>where <i>d</i> is the value that depends on the I2CPSC (see <a href="#">Section 27.1.3</a>).</p> <p>This register must be configured while the I2C is still in reset (nIRS = 0).</p> |

### 27.6.6 I2C Data Count Register (I2CCNT)

The I2C data count register is a 16-bit memory-mapped register used to count received or transmitted data bytes. This register is also used to generate the STOP condition that terminates the transfer after the counter reaches zero. [Figure 27-18](#) and [Table 27-10](#) describe this register.

**Figure 27-18. I2C Data Count Register (I2CCNT) [offset = 14h]**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 27-10. I2C Data Count Register (I2CCNT) Field Descriptions**

| Bit  | Field | Value   | Description                                                                                                                                                                     |
|------|-------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | CNT   | 0-FFFFh | Data counter<br>This down counter is used to generate a stop condition, if a stop condition is specified (STP = 1).<br><b>Note: I2CCNT is a don't care when RM is set to 1.</b> |
|      |       | 0       | The data counter is 65536.                                                                                                                                                      |
|      |       | 1       | The data counter is 1.                                                                                                                                                          |

### 27.6.7 I2C Data Receive Register (I2CDRR)

The I2C data receive register is a 16-bit memory-mapped register used by the device to read the received data. [Figure 27-19](#) and [Table 27-11](#) describe this register.

**Figure 27-19. I2C Data Receive Register (I2CDRR) [offset = 18h]**

LEGEND: R = Read only; -n = value after reset

**Table 27-11. I2C Data Receive Register (I2CDRR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                 |
|------|----------|-------|-------------------------------------------------------------------------------------------------------------|
| 15-8 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                      |
| 7-0  | DATARX   | 0-FFh | Receive data<br>A read from this register clears the RXRDY bit and clears code 4h from the I2CIVR register. |

## 27.6.8 I2C Slave Address Register (I2CSAR)

The I2C slave address register is a 16-bit memory-mapped register used to specify the address of the slave device to communicate to on the I2C bus. [Figure 27-20](#) and [Table 27-12](#) describe this register.

**Figure 27-20. I2C Slave Address Register (I2CSAR) [offset = 1Ch]**

|          |    |   |          |
|----------|----|---|----------|
| 15       | 10 | 9 | 0        |
| Reserved |    |   | SA       |
| R-0      |    |   | R/W-3FFh |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 27-12. I2C Slave Address Register (I2CSAR) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                     |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-10 | Reserved | 0     | Reads return 0. Writes have no effect.                                                                                                                                                                                          |
| 9-0   | SA       |       | 7- or 10-bit programmable slave address<br>In either mode, all 10-bits are readable and writable. Bits 7, 8, and 9 should only be used in 10-bit address mode. <a href="#">Table 27-13</a> lists the correct mode for each bit. |

**Table 27-13. Correct Mode for SA Bits**

| Bits Used | Mode              | Value of XA |
|-----------|-------------------|-------------|

**Table 27-15. I2C Mode Register (I2CMDR) Field Descriptions**

| Bit | Field    | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | NACKMOD  | 0<br>1 | No-acknowledge (NACK) mode<br><br>This bit is used to send an acknowledge (ACK) or a no-acknowledge (NACK) to the transmitter. This bit is only applicable when the I2C is in receiver mode. In master receiver mode, when the internal data counter decrements to zero, the I2C sends a NACK. The master receiver I2C finishes a transfer when it sends a NACK. The I2C ignores ICCNT when NACKMOD is 1. The NACKMOD bit should be set before the rising edge of the last data bit if a NACK must be sent, and this bit is cleared once a NACK has been sent.<br><br>The I2C sends an ACK to the transmitter during the acknowledge cycle.<br>The I2C sends a NACK to the transmitter during the acknowledge cycle. |
| 14  | FREE     | 0<br>1 | Free running bit<br><br>This bit is used to determine the state of the I2C when a breakpoint is encountered in the high level language (HLL) debugger.<br><br>The I2C stops immediately if SCL is low and keeps driving SCL low if the I2C master is a transmitter/receiver. If SCL is high, I2C waits until SCL becomes low and then stops. If the I2C is a slave, it will stop when the transmission/reception completes.<br>The I2C runs free.                                                                                                                                                                                                                                                                    |
| 13  | STT      | 0<br>1 | Start condition<br><br>The start condition bit works with the STP bit (master only mode). The STT and STP bits are configured to generate different transfer formats (see Table 27-16). The STT and STP bits can be used to terminate the repeat mode. This bit takes one I2C module clock cycle to set.<br><br>The STT is reset to 0 by the hardware after the START condition has been generated.<br>STT is set to 1 by the device to generate a START condition. In master mode, setting STT to 1 generates a START condition.                                                                                                                                                                                    |
| 12  | Reserved | 0      | Reads return 0. Writes have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 11  | STP      | 0<br>1 | Stop condition<br><br>1(Master mode only) This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when ICCNT passes 0 when the I2C is in non-repeat mode (RM=0). In repeat mode (RM=1), the stop condition is generated if STP bit is 1. In transmitter mode, I2CTXRDY needs to be 1 (that is, you have to set STP bit unless you write data into I2CDXR).<br><br>STP is reset to 0 by the hardware after the STOP condition has been generated.<br>STP is set to 1 by the device to generate a STOP condition.                                                                            |
| 10  | MST      | 0<br>1 | Master/slave mode bit<br><br>This bit determines whether the module will operate in master or slave mode; see Table 27-17. This bit is cleared after generating a STOP condition. The BB bit is cleared first, and MST bit is cleared second. Before starting the next transaction in master mode, this bit must be confirmed to be cleared.<br><br>The module is in the slave mode and the clock is received from the master device.<br>The module is in the master mode and it generates the clock. This bit is cleared when the transfer has completed.                                                                                                                                                           |

**Table 27-15. I2C Mode Register (I2CMDR) Field Descriptions (continued)**

| Bit | Field | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9   | TRX   | 0<br>1 | <p>Transmit/receive bit</p> <p>This bit determines the direction of data transmission of the I2C module. See <a href="#">Table 27-17</a>.</p> <p>0 The module is in the receive mode and data on the SDA line is shifted into the data register I2CDRR.</p> <p>1 The module is in the transmit mode and the data in the I2CDXR is shifted out on the SDA line.</p>                                                                                                                                                                                                                                                                                                                                           |
| 8   | XA    | 0<br>1 | <p>Expand address enable bit</p> <p>This bit controls the addressing mode. When XA is set to 1, the I2C does not support the combined format in master mode operations. However, the I2C will acknowledge and support the formats when configured as a slave. This bit needs to be configured even if the I2C is in slave mode.</p> <p>0 The mode is set to 7-bit addressing mode (normal address mode).</p> <p>1 The mode is set to 10-bit addressing mode (expanded address mode).</p>                                                                                                                                                                                                                     |
| 7   | RM    | 0<br>1 | <p>Repeat mode enable bit (Master mode only)</p> <p>This bit is a 'don't care' if the module is configured in slave mode (MST = 0); see <a href="#">Table 27-16</a>. Each time a byte of data is received, the user should decide whether or not to continue receiving more data. See <a href="#">Figure 27-23</a> for a diagram of this function.</p> <p>0 The mode is not in repeat mode.</p> <p>1 In repeat mode, data is continuously transmitted out of the ICDXR or received into the ICDRR until the STP bit is set to 1 regardless of ICCNT value. See <a href="#">Table 27-16</a> for module conditions.</p>                                                                                        |
| 6   | DLB   | 0<br>1 | <p>Digital loop back enable bit</p> <p>This bit disables or enables the digital loopback mode of the I2C. This bit only applies in Master transmitter mode.</p> <p>0 Digital loop back mode is disabled.</p> <p>1 Digital loop back mode is enabled. In digital loop back mode, data transmitted out of the I2CDXR will be received in the I2CDRR. The address of the I2COAR is output on SDA.</p>                                                                                                                                                                                                                                                                                                           |
| 5   | nIRS  | 0<br>1 | <p>I2C reset enable bit</p> <p>When set to 0, this bit will place all status registers in this module to their default state. Resetting nIRS during a data transfer can hang the I2C bus.</p> <p>0 I2C is in reset.</p> <p>1 I2C is out of reset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4   | STB   | 0<br>1 | <p>Start byte mode enable bit (Master mode only)</p> <p>The Start byte mode bit is set to 1 by the CPU to configure the I2C in Start byte mode. The I2C sends "00000001" regardless of the I2CSAR value. Refer to the Philips I2C specification for more details.</p> <p>0 The module is not in START byte mode.</p> <p>1 The module is in START byte mode.</p>                                                                                                                                                                                                                                                                                                                                              |
| 3   | FDF   | 0<br>1 | <p>Free data format enable bit</p> <p>This bit configures the module to operate in free data format mode (see <a href="#">Table 27-17</a>) in both master and slave modes. When FDF is 0, ARDY is asserted after ACK for the slave address. When FDF is 1, there is no slave address. Therefore, ARDY is asserted after sending the start condition. FDF mode is not supported in digital loop back mode.</p> <p>0 The module is not in free data format mode.</p> <p>1 The module is in free data format mode.</p>                                                                                                                                                                                          |
| 2-0 | BC    |        | <p>Bit count</p> <p>This bit defines the number of bits starting from the LSB (excluding the acknowledge bit) that are sent on the bus when data is written to the data transmit register.</p> <p>If the bits BC0, BC1, and BC2 are all 0, then the number of bits sent on the bus is 8. If the bit count bits are a non-zero value, then the number of bits sent on the bus is that value. The value "001" is reserved. When performing a transfer using the bit count of, for example, n (where n is nonzero), only the n least significant bits in the data receive register are valid and correct. The rest of the bits should be disregarded. See <a href="#">Table 27-18</a> for more information.</p> |

### 27.6.11 I2C Interrupt Vector Register (I2CIVR)

The I2C interrupt vector register is a 16-bit memory-mapped register used to indicate the occurrence of an interrupt. [Figure 27-24](#) and [Table 27-19](#) describe this register.

**Figure 27-24. I2C Interrupt Vector Register (I2CIVR) [offset = 28h]**

| 2-0   | INTCODE  | 0-3h  | <p>Interrupt Code Bits</p> <p>This binary coded interrupt vector indicates which interrupt has occurred. If there is more than one interrupt pending, reading I2CIVR provides the vector for the highest-priority interrupt that is pending.</p> <p>Reading the I2CIVR will clear the corresponding flags in I2CSTR for AL, NACK and SCD as long as those interrupts are enabled. A new interrupt will be generated for each pending source.</p> <p>Reading I2CIVR will clear the INTCODE for AL, NACK, SCD, AAS, RXRDY and TXRDY. Reading I2CIVR <b>will not</b> clear the INTCODE for ARDY.</p> <p>The INTCODE for certain codes can also be cleared by either writing a 1 to the corresponding interrupt flag bits in I2CSTR, or by reading and writing to the receive or transmit registers. See <a href="#">Section 27.6.3</a> for more details.</p> <p>Users must read (clear) the I2CIVR before doing another start otherwise the I2CIVR could contain incorrect (old interrupt flag) value.</p> |

**Table 27-20. Interrupt Codes for INTCODE Bits**

| Code | INTCODE(2-0)           | Interrupt Occurred           |
|------|------------------------|------------------------------|
| 00h  | 000                    | none                         |
| 01h  | 001 (highest priority) | Arbitration lost (AL)        |
| 02h  | 010                    | No acknowledgement (NACK)    |
| 03h  | 011                    | Register access ready (ARDY) |
| 04h  | 100                    | Receive data ready (RXRDY)   |
| 05h  | 101                    | Transmit data ready (TXRDY)  |
| 06h  | 110                    | Stop condition detect (SCD)  |
| 07h  | 111 (lowest priority)  | Address as slave (AAS)       |

### 27.6.12 I2C Extended Mode Register (I2CEMDR)

The I2C extended mode register is a 16-bit memory-mapped register that contains additional mode select bits. [Figure 27-25](#) and [Table 27-21](#) describe this register.

**Figure 27-25. I2C Extended Mode Register (I2CEMDR) [offset = 2Ch]**

| 1    | IGNACK   | 0     | Ignore NACK mode<br>The master transmitter will operate normally, discontinue the data transfer, and set the ARDY and NACK status bits when a NACK signal is received from the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|      |          | 1     | The master transmitter will ignore a NACK received from the slave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0    | BCM      |       | Backwards compatibility mode<br>When set to 1, the I2C is compatible with previous versions of the I2C. This means the TXRDY interrupt is generated in slave-transmit mode when TXRDY is set and the I2C needs more data to transmit. This behavior causes an extra TXRDY interrupt to be generated because the I2C recognizes the end of transfer after generating an interrupt for the next byte of data.<br>When BCM is 0, the TXRDY interrupt in slave-transmit mode is generated when XSMT = 1. In this case, the I2C generates an interrupt for the next byte after receiving the ACK from previous data. The setting of this bit only applies to slave transmit mode. |
|      |          | 0     | The I2C is <b>not</b> in compatibility mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|      |          | 1     | The I2C is in compatibility mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 27.6.13 I2C Prescale Register (I2CPSC)

The I2C prescaler register is a 16-bit memory-mapped register used for dividing down the VBUS\_CLK to obtain a module clock frequency between 6.7 MHz and 13.3 MHz. [Figure 27-26](#) and [Table 27-22](#) describe this register.

**Figure 27-26. I2C Prescale Register (I2CPSC) [offset = 30h]**

## 28.1 Introduction

This document provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the microcontroller. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC control module and is considered integral to the EMAC/MDIO peripheral.

### 28.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

### 28.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbps operation.
- Standard Media Independent Interface (MII) and/or Reduced Media Independent Interface (RMII) to physical layer device (PHY).
- EMAC acts as DMA master to either internal or external device memory space.
- Eight receive channels with VLAN tag discrimination for receive quality-of-service (QOS) support.
- Eight transmit channels with round-robin or fixed priority for transmit quality-of-service (QOS) support.
- Ether-Stats and 802.3-Stats statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selection for reception on a single channel.
- Multicast frames selection for reception on a single channel.
- Promiscuous receive mode frames selection for reception on a single channel (all frames, all good frames, short frames, error frames).
- Hardware flow control.
- 8k-byte local EMAC descriptor memory that allows the peripheral to operate on descriptors without affecting the CPU. The descriptor memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. (This memory is also known as CPPI RAM.)
- Programmable interrupt logic permits the software driver to restrict the generation of back-to-back interrupts, which allows more work to be performed in a single call to the interrupt service routine.

### 28.1.3 Functional Block Diagram

Figure 28-1 shows the three main functional modules of the EMAC/MDIO peripheral:

- EMAC control module
- EMAC module
- MDIO module

The EMAC control module is the main interface between the device core processor to the EMAC and MDIO modules. The EMAC control module controls device interrupts and incorporates an 8k-byte internal RAM to hold EMAC buffer descriptors (also known as CPPI RAM).

The MDIO module implements the 802.3 serial management interface to interrogate and control up to 32 Ethernet PHYs connected to the device by using a shared two-wire bus. Host software uses the MDIO module to configure the autonegotiation parameters of each PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC module for correct operation. The module is designed to allow almost transparent operation of the MDIO interface, with very little maintenance from the core processor.

The EMAC module provides an efficient interface between the processor and the network. The EMAC on this device supports 10Base-T (10 Mbits/sec) and 100BaseTX (100 Mbits/sec), half-duplex and full-duplex mode, and hardware flow control and quality-of-service (QoS) support.

Figure 28-1 shows the main interface between the EMAC control module and the CPU. The following connections are made to the device core:

- The DMA bus connection from the EMAC control module allows the EMAC module to read and write both internal and external memory through the DMA memory transfer controller.
- The EMAC control, EMAC, and MDIO modules all have control registers. These registers are memory-mapped into device memory space. Along with these registers, the control module's internal CPPI RAM is mapped into this same range.
- The EMAC and MDIO interrupts are combined into four interrupt signals within the control module. The Vectored Interrupt Manager (VIM) receives all four interrupt signals from the combiner and submits these interrupt requests to the CPU.

Figure 28-1. EMAC and MDIO Block Diagram

### 28.1.4 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

## 28.2 Architecture

This section discusses the architecture and basic function of the EMAC peripheral.

### 28.2.1 Clock Control

All internal EMAC logic is clocked synchronously on the VCLKA4 domain. Please refer to the *Architecture* chapter for more details.

The MDIO clock is based on a divide-down of the VCLK3 peripheral bus clock and is specified to run up to 2.5 MHz (although typical operation would be 1.0 MHz). Because the VCLK3 peripheral clock frequency is configurable, the application software or driver must control the divide-down value.

The transmit and receive clock sources are provided by the external PHY to the MII\_TXCLK and MII\_RXCLK pins or to the RMI reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The MII interface frequencies for the transmit and receive clocks are fixed by the IEEE 802.3 specification as:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

The RMI interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

### 28.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is  $2K \times 32$  bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories such as the CPU RAM. There are some tradeoffs in terms of interconnect bandwidth when descriptors are placed in the CPU RAM, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

### 28.2.3 Signal Descriptions

The microcontrollers support both the MII and the RMI interfaces. Only one of these two interfaces can be used at a time. A separate control register in the I/O Multiplexing Module (IOMM) allows the application to indicate the actual interface being used. This is the bit 24 of the PINMMR29 control register. This bit is set by default and selects the RMI interface. The application can select the MII interface by clearing this bit. Please refer to the *I/O Multiplexing and Control Module (IOMM)* chapter for more details on the procedure to configure the PINMMR registers.

Each of the EMAC and MDIO signals for the MII and RMI interfaces are multiplexed with other I/O functions on this microcontroller. Please refer to [Section 28.2.4](#) for information on configuration of the multiplexing control registers to enable the MII / RMI connections to these I/Os.

#### 28.2.3.1 Media Independent Interface (MII) Connections

[Figure 28-2](#) shows a device with integrated EMAC and MDIO interfaced via a MII connection in a typical system. The EMAC module does not include a transmit error (MTXER) pin. In the case of transmit error, CRC inversion is used to negate the validity of the transmitted frame.

The individual EMAC and MDIO signals for the MII interface are summarized in [Table 28-1](#). For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 28-2. Ethernet Configuration—MII Connections**

**Table 28-1. EMAC and MDIO Signals for MII Interface**

| Signal       | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MII_TXCLK    | I    | Transmit clock (MII_TXCLK). The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MII_TXD and MII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                                       |
| MII_TXD[3-0] | O    | Transmit data (MII_TXD). The transmit data pins are a collection of 4 data signals comprising 4 bits of data. MTDX0 is the least-significant bit (LSB). The signals are synchronized by MII_TXCLK and valid only when MII_TXEN is asserted.                                                                                                                                                                                                                                                                                                                                                                             |
| MII_TXEN     | O    | Transmit enable (MII_TXEN). The transmit enable signal indicates that the MII_TXD pins are generating nibble data for use by the PHY. It is driven synchronously to MII_TXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MII_COL      | I    | Collision detected (MII_COL). In half-duplex operation, the MII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_COL pin is used for hardware transmit flow control. Asserting the MII_COL pin will stop packet transmissions; packets in the process of being transmitted when MII_COL is asserted will complete transmission. The MII_COL pin should be held low if hardware transmit flow control is not used. |
| MII_CRS      | I    | Carrier sense (MII_CRS). In half-duplex operation, the MII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to MII_TXCLK nor MII_RXCLK.<br><br>In full-duplex operation, the MII_CRS pin should be held low.                                                                                                                                                                                                                                                        |
| MII_RXCLK    | I    | Receive clock (MII_RXCLK). The receive clock is a continuous clock that provides the timing reference for receive operations. The MII_RXD, MII_RXDV, and MII_RXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.                                                                                                                                                                                                                                                                                                               |
| MII_RXD[3-0] | I    | Receive data (MII_RXD). The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRDX0 is the least-significant bit (LSB). The signals are synchronized by MII_RXCLK and valid only when MII_RXDV is asserted.                                                                                                                                                                                                                                                                                                                                                                               |
| MII_RXDV     | I    | Receive data valid (MII_RXDV). The receive data valid signal indicates that the MII_RXD pins are generating nibble data for use by the EMAC. It is driven synchronously to MII_RXCLK.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| MII_RXER     | I    | Receive error (MII_RXER). The receive error signal is asserted for one or more MII_RXCLK periods to indicate that an error was detected in the received frame. This is meaningful only during data reception when MII_RXDV is active.                                                                                                                                                                                                                                                                                                                                                                                   |
| MDIO_CLK     | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                                                                                                                                                                                                                                                                                     |
| MDIO_D       | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.                                                                                                                                                                                                                                                       |

### 28.2.3.2 Reduced Media Independent Interface (RMII) Connections

Figure 28-3 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 28-2. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 28-3. Ethernet Configuration—RMII Connections**

**Table 28-2. EMAC and MDIO Signals for RMII Interface**

| Signal          | Type | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RMII_TXD[1-0]   | O    | Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.                                                                                                                                        |
| RMII_TXEN       | O    | Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.                                                                                                                                                                                     |
| RMII_MHZ_50_CLK | I    | RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.                                                                                                                                                                                                      |
| RMII_RXD[1-0]   | I    | Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted.                                                                                                            |
| RMII_CRS_DV     | I    | Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid.                                                                                                                                                                                                                                                  |
| RMII_RXER       | I    | Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.                                                                                                                                                                                                                                     |
| MDIO_CLK        | O    | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).                                                                               |
| MDIO_D          | I/O  | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

## 28.2.4 MII / RMII Signal Multiplexing Control

Each of the MII and RMII interface signals are multiplexed with other functions on this microcontroller. The application must configure the control registers in the I/O multiplexing module in order to enable the MII/RMII functionality on the corresponding I/Os. [Table 28-3](#) shows the byte to be configured to enable the MDIO functions. [Table 28-4](#) shows the byte to be configured to enable the MII or RMII functions. Please refer to the *I/O Multiplexing and Control Module (IOMM)* chapter for more details on the procedure to configure the PINMMR registers.

**Table 28-3. MDIO Multiplexing Control**

| MDIO Signal Name | Control for Selecting EMAC / MDIO Signal |
|------------------|------------------------------------------|
| MDIO_CLK         | PINMMR7 [15:8] = 0b00000100              |
| MDIO_D           | PINMMR8 [15:8] = 0b00000100              |

**Table 28-4. MII / RMII Multiplexing Control**

| MII / RMII Signal Name     | Control for Selecting MII Signal | Control for Selecting RMII Signal |
|----------------------------|----------------------------------|-----------------------------------|
| MII_TXCLK                  | PINMMR17 [7:0] = 0b00000010      | -                                 |
| MII_TXD[3]                 | PINMMR14 [7:0] = 0b00000100      | -                                 |
| MII_TXD[2]                 | PINMMR13 [31:24] = 0b00000100    | -                                 |
| MII_TXD[1] / RMII_TXD[1]   | PINMMR13 [15:8] = 0b00000100     | PINMMR13 [15:8] = 0b00001000      |
| MII_TXD[0] / RMII_TXD[0]   | PINMMR13 [7:0] = 0b00000100      | PINMMR13 [7:0] = 0b00001000       |
| MII_TXEN / RMII_TXEN       | PINMMR13 [23:16] = 0b00000100    | PINMMR13 [23:16] = 0b00001000     |
| MII_COL                    | PINMMR20 [23:16] = 0b00000100    | -                                 |
| MII_CRS / RMII_CRSDV       | PINMMR17 [23:16] = 0b00000010    | PINMMR17 [23:16] = 0b00000100     |
| MII_RXCLK / RMII_50MHZ_CLK | PINMMR14 [15:8] = 0b00000010     | PINMMR14 [15:8] = 0b00000100      |
| MII_RXD[3]                 | PINMMR12 [31:24] = 0b00000100    | -                                 |
| MII_RXD[2]                 | PINMMR12 [23:16] = 0b00000100    | -                                 |
| MII_RXD[1] / RMII_RXD[1]   | PINMMR12 [7:0] = 0b00000010      | PINMMR12 [7:0] = 0b00000100       |
| MII_RXD[0] / RMII_RXD[0]   | PINMMR11 [31:24] = 0b00000100    | PINMMR11 [31:24] = 0b00001000     |
| MII_RXDV                   | PINMMR19 [15:8] = 0b00000010     | -                                 |
| MII_RXER / RMII_RXER       | PINMMR10 [7:0] = 0b00000010      | PINMMR10 [7:0] = 0b00000100       |

## 28.2.5 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

### 28.2.5.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in [Figure 28-4](#) and described in [Table 28-5](#). The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

**Figure 28-4. Ethernet Frame Format**

Legend: SFD=Start Frame Delimeter; FCS=Frame Check Sequence (CRC)

**Table 28-5. Ethernet Frame Description**

| Field       | Bytes                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Preamble    | 7                     | Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SFD         | 1                     | Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Destination | 6                     | Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.                                                                                                                                                                                                        |
| Source      | 6                     | Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Len         | 2                     | Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data        | 46 to (RXMAXLEN - 18) | Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less than 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS. |
| FCS         | 4                     | Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.                                                                                                                                                                                                                                                                             |

## 28.2.5.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

## 28.2.6 Programming Interface

### 28.2.6.1 Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in [Figure 28-5](#) and described in [Table 28-6](#).

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in [Figure 28-6](#).

**Figure 28-5. Basic Descriptor Format**

| Word<br>Offset | Bit Fields              |    |               |
|----------------|-------------------------|----|---------------|
|                | 31                      | 16 | 15 0          |
| 0              | Next Descriptor Pointer |    |               |
| 1              | Buffer Pointer          |    |               |
| 2              | Buffer Offset           |    | Buffer Length |
| 3              | Flags                   |    | Packet Length |

**Table 28-6. Basic Descriptor Description**

| Word Offset | Field                   | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Next Descriptor Pointer | The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list. |
| 1           | Buffer Pointer          | The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.                                                                                                                                                                                                                                                                                                                                                            |
| 2           | Buffer Offset           | The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.                                                                                                                                                                                                                                                                                                                                          |
|             | Buffer Length           | The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.                                                                                                                                                                                                                                                                                                                                                      |
| 3           | Flags                   | The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in <a href="#">Section 28.2.6.4</a> and <a href="#">Section 28.2.6.5</a> .                                                                                                                                                                                                                        |
|             | Packet Length           | The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.                                                                                                                                                                                                                                       |

**Figure 28-6. Typical Descriptor Linked List**

### 28.2.6.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked lists as discussed in [Section 28.2.6.1](#). The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). The EMAC supports eight channels for transmit and eight channels for receive. The corresponding head descriptor pointers are:

- TX $n$ HDP - Transmit Channel  $n$  DMA Head Descriptor Pointer Register
- RX $n$ HDP - Receive Channel  $n$  DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its "next" pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its "next descriptor" pointer must be initialized to 0.

The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL "next" pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the "next" pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor's "next" pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list. [Figure 28-7](#), [Figure 28-8](#), and [Figure 28-9](#) illustrate transmit operations.

**Figure 28-7. Transmit Packet Add Flow Chart**

Note: Software TX QUEUE ACTIVE is an indication that at least one packet is in the TX queue (from the software viewpoint).

**Figure 28-8. Generate Transmit Packet Flow Chart**

BD = Buffer Descriptor

### Figure 28-9. Transmit Queue Interrupt Processing Flow Chart

BD = Buffer Descriptor

Note: Whether or not to process more than one packet is a software decision.

### 28.2.6.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in [Section 28.2.6.1](#), using the linked list queue mechanism discussed in [Section 28.2.6.2](#).

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

The EMAC supports eight channels for transmit and eight channels for receive. The corresponding completion pointer registers are:

- TX $n$ CP - Transmit Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register
- RX $n$ CP - Receive Channel  $n$  Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

Interrupts in the EMAC control module are routed to the Vectored Interrupt Manager (VIM) as four separate interrupt requests. The interrupt configuration determines whether or not an active interrupt request actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts are set in the EMAC control module: C0RXEN and C0TXEN
3. The VIM is configured to accept C0\_RX\_PULSE and C0\_TX\_PULSE interrupts from the EMAC control module
4. The normal mode (IRQ) interrupts are enabled in the Cortex-R4F CPU

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC control module interrupts.

EMAC interrupts are acknowledged when the application software updates the value of TX $n$ CP or RX $n$ CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.

EMAC control module interrupts are acknowledged when the application software writes the appropriate C0TX or C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

### 28.2.6.4 Transmit Buffer Descriptor Format

A transmit (TX) buffer descriptor ([Figure 28-10](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 28-1](#) shows the transmit buffer descriptor described by a C structure.

**Figure 28-10. Transmit Buffer Descriptor Format**

**Example 28-1. Transmit Buffer Descriptor in C Structure Format**

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u

```

#### **28.2.6.4.1 Next Descriptor Pointer**

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### **28.2.6.4.2 Buffer Pointer**

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### **28.2.6.4.3 Buffer Offset**

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte-aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

#### **28.2.6.4.4 Buffer Length**

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

#### **28.2.6.4.5 Packet Length**

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

#### **28.2.6.4.6 Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### 28.2.6.4.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

#### 28.2.6.4.8 Ownership (OWNER) Flag

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

#### 28.2.6.4.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

#### 28.2.6.4.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

#### 28.2.6.4.11 Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

### 28.2.6.5 Receive Buffer Descriptor Format

A receive (RX) buffer descriptor ([Figure 28-11](#)) is a contiguous block of four 32-bit data words aligned on a 32-bit boundary that describes a packet or a packet fragment. [Example 28-2](#) shows the receive buffer descriptor described by a C structure.

### 28.2.6.5.1 Next Descriptor Pointer

This pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

### 28.2.6.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

**Figure 28-11. Receive Buffer Descriptor Format**

### Example 28-2. Receive Buffer Descriptor in C Structure Format

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u
#define EMAC_DSC_FLAG_JABBER 0x02000000u
#define EMAC_DSC_FLAG_OVERSIZE 0x01000000u
#define EMAC_DSC_FLAG_FRAGMENT 0x00800000u
#define EMAC_DSC_FLAG_UNDERSIZED 0x00400000u
#define EMAC_DSC_FLAG_CONTROL 0x00200000u
#define EMAC_DSC_FLAG_OVERRUN 0x00100000u
#define EMAC_DSC_FLAG_CODEERROR 0x00080000u
#define EMAC_DSC_FLAG_ALIGNERROR 0x00040000u
#define EMAC_DSC_FLAG_CRCERROR 0x00020000u
#define EMAC_DSC_FLAG_NOMATCH 0x00010000u

```

#### 28.2.6.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

#### **28.2.6.5.4 Buffer Length**

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

#### **28.2.6.5.5 Packet Length**

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

#### **28.2.6.5.6 Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

#### **28.2.6.5.7 End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

#### **28.2.6.5.8 Ownership (OWNER) Flag**

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

#### **28.2.6.5.9 End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

#### **28.2.6.5.10 Teardown Complete (TDOWNCMPLT) Flag**

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**28.2.6.5.11 Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**28.2.6.5.12 Jabber Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**28.2.6.5.13 Oversize Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**28.2.6.5.14 Fragment Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**28.2.6.5.15 Undersized Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

**28.2.6.5.16 Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

**28.2.6.5.17 Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

**28.2.6.5.18 Code Error (CODEERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**28.2.6.5.19 Alignment Error (ALIGNERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**28.2.6.5.20 CRC Error (CRCERROR) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

**28.2.6.5.21 No Match (NOMATCH) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

### 28.2.7 EMAC Control Module

The EMAC control module (Figure 28-12) interfaces the EMAC and MDIO modules to the rest of the system, and also provides a local memory space to hold EMAC packet buffer descriptors. Local memory is used to help avoid contention with device memory spaces. Other functions include the bus arbiter, and interrupt logic control.

**Figure 28-12. EMAC Control Module Block Diagram**

#### 28.2.7.1 Internal Memory

The EMAC control module includes 8K bytes of internal memory (CPPI buffer descriptor memory). The internal memory block is essential for allowing the EMAC to operate more independently of the CPU. It also prevents memory underflow conditions when the EMAC issues read or write requests to descriptor memory. (Memory accesses to read or write the actual Ethernet packet data are protected by the EMAC's internal FIFOs).

A descriptor is a 16-byte memory structure that holds information about a single Ethernet packet buffer, which may contain a full or partial Ethernet packet. Thus with the 8K memory block provided for descriptor storage, the EMAC module can send and received up to a combined 512 packets before it needs to be serviced by application or driver software.

#### 28.2.7.2 Bus Arbiter

The EMAC control module bus arbiter operates transparently to the rest of the system. It is used:

- To arbitrate between the CPU and EMAC buses for access to internal descriptor memory.
- To arbitrate between internal EMAC buses for access to system memory.

### 28.2.7.3 Interrupt Control

Interrupt conditions generated by the EMAC and MDIO modules are combined into four interrupt signals that are routed to the Vectored Interrupt Manager (VIM); the VIM then relays the interrupt signals to the CPU. The EMAC control module uses two sets of registers to control the interrupt signals to the CPU:

- C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN registers enable the pulse signals that are mapped to the VIM
- INTCONTROL, C0RXIMAX, and C0TXIMAX registers enable interrupt pacing to limit the number of interrupt pulses generated per millisecond

Interrupts must be acknowledged by writing the appropriate value to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

### 28.2.8 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

The MDIO module does not support the "Clause 45" interface.

#### 28.2.8.1 MDIO Module Components

The MDIO module ([Figure 28-13](#)) interfaces to the PHY components through two MDIO pins (MDIO\_CLK and MDIO), and to the CPU through the EMAC control module and the configuration bus. The MDIO module consists of the following logical components:

- MDIO clock generator
- Global PHY detection and link state monitoring
- Active PHY monitoring
- PHY register user access

**Figure 28-13. MDIO Module Block Diagram**

#### 28.2.8.1.1 MDIO Clock Generator

The MDIO clock generator controls the MDIO clock based on a divide-down of the VCLK3 peripheral clock in the EMAC control module. The MDIO clock is specified to run up to 2.5 MHz, although typical operation would be 1.0 MHz. Since the VCLK3 peripheral clock frequency is configurable, the application software or driver controls the divide-down amount. See the device datasheet for peripheral clock speed specifications.

#### 28.2.8.1.2 Global PHY Detection and Link State Monitoring

The MDIO module continuously polls all 32 MDIO addresses in order to enumerate the PHY devices in the system. The module tracks whether or not a PHY on a particular address has responded, and whether or not the PHY currently has a link. Using this information allows the software application to quickly determine which MDIO address the PHY is using.

#### 28.2.8.1.3 Active PHY Monitoring

Once a PHY candidate has been selected for use, the MDIO module transparently monitors its link state by reading the MDIO PHY link status register (LINK). Link change events are stored on the MDIO device and can optionally interrupt the CPU. This allows the system to poll the link status of the PHY device without continuously performing costly MDIO accesses.

#### 28.2.8.1.4 PHY Register User Access

When the CPU must access MDIO for configuration and negotiation, the PHY access module performs the actual MDIO read or write operation independent of the CPU. This allows the CPU to poll for completion or receive an interrupt when the read or write operation has been performed. The user access registers USERACCESS<sub>n</sub> allows the software to submit the access requests for the PHY connected to the device.

### 28.2.8.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL<sub>n</sub>). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL<sub>n</sub>. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS<sub>n</sub>).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS<sub>n</sub> causes ALIVE to be updated.

The USERPHYSEL<sub>n</sub> is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL<sub>n</sub>.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS<sub>n</sub>. When the application sets the GO bit in USERACCESS<sub>n</sub>, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS<sub>n</sub> used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS<sub>0</sub> and USERACCESS<sub>1</sub>. The application software must check the status of the GO bit in USERACCESS<sub>n</sub> before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS<sub>n</sub> to determine the status of a read transaction.

### 28.2.8.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL<sub>n</sub>), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS<sub>n</sub>). Since only one PHY is used in this device, the application software can use one USERACCESS<sub>n</sub> to trigger a completion interrupt; the other USERACCESS<sub>n</sub> is not setup.

### 28.2.8.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS<sub>n</sub>) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS<sub>n</sub>) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS<sub>n</sub> corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS<sub>n</sub> for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS<sub>n</sub> used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

### 28.2.8.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS<sub>n</sub>) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS<sub>n</sub>) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS<sub>n</sub> corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS<sub>n</sub> after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS<sub>n</sub>. Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS<sub>n</sub> used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

#### 28.2.8.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS $n$ ) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG\_read( regadr, phyadr )                      Start the process of reading a PHY register
- PHYREG\_write( regadr, phyadr, data )              Start the process of writing a PHY register
- PHYREG\_wait( )                                        Synchronize operation (make sure read/write is idle)
- PHYREG\_waitResults( results )                      Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG\_wait() after every write, and PHYREG\_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in [Example 28-3](#) (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS $n$  on PHY register reads (does not follow the procedure outlined in [Section 28.2.8.2.3](#)). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

#### Example 28-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)     | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)
#define PHYREG_write(regadr, phyadr, data)
    MDIO_REGS->USERACCESS0 =
        CSL_FMK(MDIO_USERACCESS0_G0,1u)           | /
        CSL_FMK(MDIO_USERACCESS0_WRITE,1)          | /
        CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)     | /
        CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)     | /
        CSL_FMK(MDIO_USERACCESS0_DATA, data)
#define PHYREG_wait()
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) )
#define PHYREG_waitResults( results ) {
    while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_G0) );
    results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

## 28.2.9 EMAC Module

This section discusses the architecture and basic function of the EMAC module.

### 28.2.9.1 EMAC Module Components

The EMAC module (Figure 28-14) interfaces to the outside world through the Media Independent Interface (MII) or Reduced Media Independent Interface (RMII). The interface between the EMAC module and the system core is provided through the EMAC control module. The EMAC consists of the following logical components:

- The receive path includes: receive DMA engine, receive FIFO, and MAC receiver
- The transmit path includes: transmit DMA engine, transmit FIFO, and MAC transmitter
- Statistics logic
- State RAM
- Interrupt controller
- Control registers and logic
- Clock and reset logic

**Figure 28-14. EMAC Module Block Diagram**

#### 28.2.9.1.1 Receive DMA Engine

The receive DMA engine is the interface between the receive FIFO and the system core. It interfaces to the CPU through the bus arbiter in the EMAC control module. This DMA engine is totally independent of the device DMA.

#### 28.2.9.1.2 Receive FIFO

The receive FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers receive data in preparation for writing into packet buffers in device memory.

### **28.2.9.1.3 MAC Receiver**

The MAC receiver detects and processes incoming network frames, de-frames them, and puts them into the receive FIFO. The MAC receiver also detects errors and passes statistics to the statistics RAM.

### **28.2.9.1.4 Transmit DMA Engine**

The transmit DMA engine is the interface between the transmit FIFO and the CPU. It interfaces to the CPU through the bus arbiter in the EMAC control module.

### **28.2.9.1.5 Transmit FIFO**

The transmit FIFO consists of three cells of 64-bytes each and associated control logic. The FIFO buffers data in preparation for transmission.

### **28.2.9.1.6 MAC Transmitter**

The MAC transmitter formats frame data from the transmit FIFO and transmits the data using the CSMA/CD access protocol. The frame CRC can be automatically appended, if required. The MAC transmitter also detects transmission errors and passes statistics to the statistics registers.

### **28.2.9.1.7 Statistics Logic**

The Ethernet statistics are counted and stored in the statistics logic RAM. This statistics RAM keeps track of 36 different Ethernet packet statistics.

### **28.2.9.1.8 State RAM**

State RAM contains the head descriptor pointers and completion pointers registers for both transmit and receive channels.

### **28.2.9.1.9 EMAC Interrupt Controller**

The interrupt controller contains the interrupt related registers and logic. The 26 raw EMAC interrupts are input to this submodule and masked module interrupts are output.

### **28.2.9.1.10 Control Registers and Logic**

The EMAC is controlled by a set of memory-mapped registers. The control logic also signals transmit, receive, and status related interrupts to the CPU through the EMAC control module.

### **28.2.9.1.11 Clock and Reset Logic**

The clock and reset submodule generates all the EMAC clocks and resets. For more details on reset capabilities, see [Section 28.2.15.1](#).

## **28.2.9.2 EMAC Module Operational Overview**

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC control module (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

## **28.2.10 MAC Interface**

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

### **28.2.10.1 Data Reception**

#### **28.2.10.1.1 Receive Control**

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

#### **28.2.10.1.2 Receive Inter-Frame Interval**

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

### 28.2.10.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RXnFREEBUFFER) is less than or equal to the receive channel flow control threshold register (RXnFLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

#### 28.2.10.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

#### 28.2.10.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).

- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

### 28.2.10.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

#### 28.2.10.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII\_CRS) and collision-sensing (MII\_COL) modes are disabled.

#### 28.2.10.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

#### 28.2.10.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG) delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

#### 28.2.10.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII\_CRS is deasserted within approximately 48 bit times of MII\_TXEN being deasserted, then 96 bit times is measured from MII\_TXEN. If the frame suffered a collision or MII\_CRS is not deasserted until more than approximately 48 bit times after MII\_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII\_CRS.

#### 28.2.10.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

### 28.2.10.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no affect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII\_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

### 28.2.10.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

## 28.2.11 Packet Receive Operation

### 28.2.11.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel  $n$  DMA head descriptor pointer registers (RX $n$ HDP) to 0.
- Write the MAC address hash  $n$  registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel  $n$  free buffer count registers (RX $n$ FREEBUFFER)
  - the receive channel  $n$  flow control threshold register (RX $n$ FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET) and the receive interrupt mask clear register (RXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors and initialize RX $n$ HDP.
- Enable the receive DMA controller by setting the RXEN bit in the receive control register (RXCONTROL).
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

### 28.2.11.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH $n$ EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH $n$ EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash  $n$  registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

### 28.2.11.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

#### 28.2.11.4 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RXnFREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RXnFREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

#### 28.2.11.5 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RXnFREEBUFFER). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RXnFREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

#### 28.2.11.6 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RXnCP) contains the value FFFF FFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFCh acknowledge value to RXnCP (note that there is no buffer descriptor in this case). Software may read RXnCP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFCh, if the interrupt was due to a teardown command.

### 28.2.11.7 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

### 28.2.11.8 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. [Table 28-7](#) shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

**Table 28-7. Receive Frame Treatment Summary**

| Address Match | RXCAFEN | RXCEFEN | RXCMFEN | RXCSFEN | Receive Frame Treatment                                                                                                                            |
|---------------|---------|---------|---------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | X       | X       | No frames transferred.                                                                                                                             |
| 0             | 1       | 0       | 0       | 0       | Proper frames transferred to promiscuous channel.                                                                                                  |
| 0             | 1       | 0       | 0       | 1       | Proper/undersized data frames transferred to promiscuous channel.                                                                                  |
| 0             | 1       | 0       | 1       | 0       | Proper data and control frames transferred to promiscuous channel.                                                                                 |
| 0             | 1       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to promiscuous channel.                                                                      |
| 0             | 1       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.    |
| 0             | 1       | 1       | 0       | 1       | Proper/undersized/fragment/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control frames are transferred.       |
| 0             | 1       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.            |
| 0             | 1       | 1       | 1       | 1       | All nonaddress matching frames with and without errors transferred to promiscuous channel.                                                         |
| 1             | X       | 0       | 0       | 0       | Proper data frames transferred to address match channel.                                                                                           |
| 1             | X       | 0       | 0       | 1       | Proper/undersized data frames transferred to address match channel.                                                                                |
| 1             | X       | 0       | 1       | 0       | Proper data and control frames transferred to address match channel.                                                                               |
| 1             | X       | 0       | 1       | 1       | Proper/undersized data and control frames transferred to address match channel.                                                                    |
| 1             | X       | 1       | 0       | 0       | Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.           |
| 1             | X       | 1       | 0       | 1       | Proper/oversize/jabber/fragment/undersized/code/align/CRC data frames transferred to address match channel. No control frames are transferred.     |
| 1             | X       | 1       | 1       | 0       | Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred. |
| 1             | X       | 1       | 1       | 1       | All address matching frames with and without errors transferred to the address match channel                                                       |

### 28.2.11.9 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO\_SOF)
- FIFO middle of frame overrun (FIFO\_MOF)
- DMA start of frame overrun (DMA\_SOF)
- DMA middle of frame overrun (DMA\_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. [Table 28-8](#) shows how the overrun condition is handled for the middle of frame overrun.

**Table 28-8. Middle of Frame Overrun Treatment**

| Address Match | RXCAFEN | RXCEFEN | Middle of Frame Overrun Treatment                                                                                                                                                                                                                                                                                                                         |
|---------------|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0       | X       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 0       | Overrun frame filtered.                                                                                                                                                                                                                                                                                                                                   |
| 0             | 1       | 1       | As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize). |
| 1             | X       | 0       | Overrun frame filtered with the appropriate overrun statistic(s) incremented.                                                                                                                                                                                                                                                                             |
| 1             | X       | 1       | As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).                                         |

## 28.2.12 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

### 28.2.12.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel  $n$  DMA head descriptor pointer registers (TX $n$ HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX $n$ HDP with the pointer to the first descriptor to start transmit operations.

### 28.2.12.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel  $n$  completion pointer register (TX $n$ CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX $n$ CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX $n$ CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

### 28.2.13 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12  $\mu$ s in 100 Mbps mode and 51.2  $\mu$ s in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12  $\mu$ s in 100 Mbps mode, or 51.2  $\mu$ s in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC control module.

### 28.2.14 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12  $\mu$ s.
- Any single latency event in request servicing can be no longer than  $(5.12 \times \text{TXCELLTHRESH}) \mu$ s.

## 28.2.15 Reset Considerations

### 28.2.15.1 Software Reset Considerations

The peripheral clock is controlled by the Global Clock Module (GCM), while the reset to the EMAC, MDIO and EMAC control module is controlled by the system module. See the Architecture chapter for more information on how to enable or disable the peripheral clock to the EMAC, MDIO and EMAC control module. For more on how the EMAC, MDIO, and EMAC control module are disabled or placed in reset at runtime, see [Section 28.2.18](#).

Within the peripheral itself, the EMAC component of the Ethernet MAC peripheral can be placed in a reset state by writing to the soft reset register (SOFTRESET). Writing a 1 to the SOFTRESET bit causes the EMAC logic to be reset and the register values to be set to their default values. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the configuration bus; it is the responsibility of the software to verify that there are no pending frames to be transferred. After writing a 1 to the SOFTRESET bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred; if a 0 is read, then a reset has occurred.

After a software reset operation, all the EMAC registers need to be reinitialized for proper data transmission, including the FULLDUPLEX bit setting in the MAC control register (MACCONTROL).

Unlike the EMAC module, the MDIO and EMAC control modules cannot be placed in reset from a register inside their memory map.

### 28.2.15.2 Hardware Reset Considerations

When a hardware reset occurs, the EMAC peripheral has its register values reset and all the components return to their default state. After the hardware reset, the EMAC needs to be initialized before being able to resume its data transmission, as described in [Section 28.2.16](#).

A hardware reset is the only means of recovering from the error interrupts (HOSTPEND), which are triggered by errors in packet buffer descriptors. Before doing a hardware reset, you should inspect the error codes in the MAC status register (MACSTATUS) that gives information about the type of software error that needs to be corrected. For detailed information on error interrupts, see [Section 28.2.17.1.4](#).

## 28.2.16 Initialization

### 28.2.16.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral becomes enabled as soon as the system reset is released, and the EMAC peripheral registers are set to their default values. The application software can configure the EMAC peripheral registers as required.

### 28.2.16.2 EMAC Control Module Initialization

The EMAC control module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

Note that although the EMAC control module and the EMAC module have slightly different functions, in practice, the type of maintenance performed on the EMAC control module is more commonly conducted from the EMAC module software (as opposed to the MDIO module).

The initialization of the EMAC control module consists of two parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC control module:
  - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, CORXIMAX, and COTXIMAX
  - Initializing the EMAC and MDIO modules
  - Enabling interrupts in the EMAC control module using the EMAC control module interrupt control registers CORXTHRESHEN, CORXEN, COTXEN, and COMISCEN.

The process of mapping the EMAC interrupts to the CPU is done through the Vectored Interrupt Manager (VIM). Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

### 28.2.16.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL $n$ ) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50  $\mu$ s to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

#### 28.2.16.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC control module interrupt control registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers (RXnHDP and TXnHDP) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel *n* free buffer count registers (RXnFREEBUFFER), receive channel *n* flow control threshold register (RXnFLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
8. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RXnHDP.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC control module registers C0RXTHRESHEN, C0RXEN, C0TXEN, and C0MISCEN.

## 28.2.17 Interrupt Support

### 28.2.17.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND $n$ : Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7
- RXTRESHPEND $n$ : Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

#### 28.2.17.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND $n$ ). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC control module) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel  $n$  completion pointer register (TX $n$ CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate C0RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

#### 28.2.17.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND $n$ ). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RXnCP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC control module after processing packets by writing the appropriate COTX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

#### **28.2.17.1.3 Statistics Interrupt**

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must acknowledge the EMAC control module after receiving statistics interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

#### **28.2.17.1.4 Host Error Interrupt**

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC control module after receiving host error interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

#### 28.2.17.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RXnTHRESHPEND). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the RXINTMASKSET register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

An RXnTHRESHPEND interrupt bit is asserted when enabled and when the channel's associated free buffer count (RXnFREEBUFFER) is less than or equal to the channel's associated flow control threshold register (RXnFLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC control module after receiving threshold interrupts by writing the appropriate CORXTHRESH key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

#### 28.2.17.2 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

##### 28.2.17.2.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

### 28.2.17.2.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW). USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC control module after receiving MDIO interrupts by writing the appropriate COMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

### 28.2.17.3 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC control module.

[Section 28.2.7.3](#) discusses the interrupt control contained in the EMAC control module. For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC control module registers CORXTHRESHEN, CORXEN, COTXEN, COMISCEN, and then reenable them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC control module also uses the EMAC control module registers INTCONTROL, COTXIMAX, and CORXIMAX to implement interrupt pacing. The application software must acknowledge the EMAC control module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 28.5.12](#) for the acknowledge key values.

### 28.2.17.4 Interrupt Multiplexing

The EMAC control module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (CORXTHRESHPULSE, CORXPULSE, COTXPULSE, COMISCPULSE) that are routed to the Vectored Interrupt Manager (VIM). The VIM is capable of relaying all four interrupt signals to the CPU.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPEND<sub>n</sub>, RXPEND<sub>n</sub>, RXTHRESHPEND<sub>n</sub>, STATPEND, HOSTPEND, LINKINT0, and USERINT0.

For more details on the interrupt mapping, see your device-specific datasheet and VIM chapter of the Technical Reference Manual.

### 28.2.18 Power Management

Each of the three main components of the EMAC peripheral can be placed in a reduced-power mode to conserve power during periods of low activity. The peripheral clock to the EMAC peripheral is controlled by the processor Global Clock Module (GCM). The GCM allows the application to enable or disable the peripheral clock to the EMAC peripheral.

The power conservation modes available for each of the three components of the EMAC/MDIO peripheral are:

- *Idle/Disabled state.* This mode stops the clocks going to the peripheral, and prevents all the register accesses. After reenabling the peripheral from this idle state, all the registers values prior to setting into the disabled state are restored, and data transmission can proceed. No reinitialization is required.
- *System reset.* The EMAC peripheral is reset by the system reset signal output from the System module. Refer to the "Architecture" chapter of the Technical Reference Manual to identify the causes of a system reset. Upon a system reset, the registers are reset to their default value. When powering-up after a system reset, all the EMAC submodules need to be reinitialized before any data transmission can happen.

For more information on the use of the GCM, see your device-specific Technical Reference Manual.

### 28.2.19 Emulation Considerations

EMAC emulation control is implemented for compatibility with other peripherals. The SOFT and FREE bits in the emulation control register (EMCONTROL) allow EMAC operation to be suspended.

When the emulation suspend state is entered, the EMAC stops processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission is completed normally without suspension. For transmission, any complete or partial frame in the transmit cell FIFO is transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics are kept for ignored frames.

Table 28-9 shows how the SOFT and FREE bits affect the operation of the emulation suspend.

---

**NOTE:** Emulation suspend has not been tested.

---

**Table 28-9. Emulation Control**

| SOFT | FREE | Description       |
|------|------|-------------------|
| 0    | 0    | Normal operation  |
| 1    | 0    | Emulation suspend |
| X    | 1    | Normal operation  |

## 28.3 EMAC Control Module Registers

Table 28-10 lists the memory-mapped registers for the EMAC control module. The base address for these registers is FCF7 8800h.

**Table 28-10. EMAC Control Module Registers**

**Table 28-23. EMAC Control Module Transmit Interrupts Per Millisecond Register (C0TXIMAX)**

| Bit  | Field    | Value  | Description                                                                                                              |
|------|----------|--------|--------------------------------------------------------------------------------------------------------------------------|
| 31-6 | Reserved | 0      | Reserved                                                                                                                 |
| 5-0  | TXIMAX   | 2h-3Fh | TXIMAX is the desired number of C0TXPULSE interrupts generated per millisecond when C0TXPACEEN is enabled in INTCONTROL. |

The pacing mechanism can be described by the following pseudo-code:

```
while(1) {
    interrupt_count = 0;

    /* Count interrupts over a 1ms window */
    for(i = 0; i < INTCONTROL[INTPRESCALE]*250; i++) {
        interrupt_count += NEW_INTERRUPT_EVENTS();

        if(i < INTCONTROL[INTPRESCALE]*pace_counter)
            BLOCK_EMAC_INTERRUPTS();
        else
            ALLOW_EMAC_INTERRUPTS();
    }

    ALLOW_EMAC_INTERRUPTS();

    if(interrupt_count > 2*TXIMAX)
        pace_counter = 255;
    else if(interrupt_count > 1.5*TXIMAX)
        pace_counter = previous_pace_counter*2 + 1;
    else if(interrupt_count > 1.0*TXIMAX)
        pace_counter = previous_pace_counter + 1;
    else if(interrupt_count > 0.5*TXIMAX)
        pace_counter = previous_pace_counter - 1;
    else if(interrupt_count != 0)
        pace_counter = previous_pace_counter/2;
    else
        pace_counter = 0;

    previous_pace_counter = pace_counter;
}
```

## 28.4 MDIO Registers

Table 28-24 lists the memory-mapped registers for the MDIO module. The base address for these registers is FCF7 8900h.

LEGEND: R/W = Read/Write; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-27. PHY Acknowledge Status Register (ALIVE) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | ALIVE |       | MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding ALIVE bit to be updated. The ALIVE bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect. |
|      |       | 0     | The PHY fails to acknowledge the access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|      |       | 1     | The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 28.4.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in [Figure 28-31](#) and described in [Table 28-28](#).

**Figure 28-31. PHY Link Status Register (LINK)**

LEGEND: R = Read only; -n = value after reset

**Table 28-28. PHY Link Status Register (LINK) Field Descriptions**

| Bit  | Field | Value | Description                                                                                                                                                                                                                                                                                                                                                            |
|------|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | LINK  |       | MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. |
|      |       | 0     | The PHY indicates it does not have a link or fails to acknowledge the read transaction.                                                                                                                                                                                                                                                                                |
|      |       | 1     | The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.                                                                                                                                                                                                                                                                       |

### 28.4.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in [Figure 28-32](#) and described in [Table 28-29](#).

**Figure 28-32. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)**

| 1    | USERPHY1 | 0<br>1 | MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1. Writing a 1 will clear the event, writing a 0 has no effect.<br>No MDIO link change event.<br>An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1. |
| 0    | USERPHY0 | 0<br>1 | MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0. Writing a 1 will clear the event, writing a 0 has no effect.<br>No MDIO link change event.<br>An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0. |

### 28.4.6 MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)

The MDIO link status change interrupt (masked) register (LINKINTMASKED) is shown in [Figure 28-33](#) and described in [Table 28-30](#).

**Figure 28-33. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-30. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)  
Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                                                           |
|------|----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                              |
| 1    | USERPHY1 | 0     | MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event, writing a 0 has no effect. |
|      |          | 0     | No MDIO link change event.                                                                                                                                                                                                                                                                                            |
|      |          | 1     | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1 and the LINKINTENB bit in USERPHYSEL1 is set to 1.                                                                                                                              |
| 0    | USERPHY0 | 0     | MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event, writing a 0 has no effect. |
|      |          | 0     | No MDIO link change event.                                                                                                                                                                                                                                                                                            |
|      |          | 1     | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 and the LINKINTENB bit in USERPHYSEL0 is set to 1.                                                                                                                              |

### 28.4.7 MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

The MDIO user command complete interrupt (unmasked) register (USERINTRAW) is shown in [Figure 28-34](#) and described in [Table 28-31](#).

**Figure 28-34. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-31. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) Field Descriptions**

| Bit  | Field       | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 0    | USERACCESS0 | <div>0</div> <div>1</div> | <div>MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS0 register has completed. Writing a 1 will clear the event, writing a 0 has no effect.</div> <div>No MDIO user command complete event.</div> <div>The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed.</div> |

#### 28.4.8 MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

The MDIO user command complete interrupt (masked) register (USERINTMASKED) is shown in [Figure 28-35](#) and described in [Table 28-32](#).

**Figure 28-35. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-32. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                               |
|------|-------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                  |
| 1    | USERACCESS1 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |
| 0    | USERACCESS0 |       | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt, writing a 0 has no effect. |
|      |             | 0     | No MDIO user command complete event.                                                                                                                                                                                                                                      |
|      |             | 1     | The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1.                                                                                                     |

### 28.4.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

The MDIO user command complete interrupt mask set register (USERINTMASKSET) is shown in [Figure 28-36](#) and described in [Table 28-33](#).

**Figure 28-36. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-33. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)  
Field Descriptions**

| Bit  | Field       | Value | Description                                                                                                                                                                                                                                                                 |
|------|-------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved    | 0     | Reserved                                                                                                                                                                                                                                                                    |
| 1    | USERACCESS1 | 0     | MDIO user interrupt mask set for USERINTMASKED[1]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS1 register. MDIO user interrupt for USERACCESS1 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is enabled.                                                                                                                                                                             |
| 0    | USERACCESS0 |       | MDIO user interrupt mask set for USERINTMASKED[0]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS0 register. MDIO user interrupt for USERACCESS0 is disabled if the corresponding bit is 0. Writing a 0 to this bit has no effect. |
|      |             | 0     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.                                                                                                                                                                            |
|      |             | 1     | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.                                                                                                                                                                             |

### 28.4.11 MDIO User Access Register 0 (USERACCESS0)

The MDIO user access register 0 (USERACCESS0) is shown in [Figure 28-38](#) and described in [Table 28-35](#).

**Figure 28-38. MDIO User Access Register 0 (USERACCESS0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-35. MDIO User Access Register 0 (USERACCESS0) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | GO       | 0-1     | Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30    | WRITE    | 0<br>1  | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.<br>The user command is a read operation.<br>The user command is a write operation.                                                                                                                                                                                                |
| 29    | ACK      | 0-1     | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.                                                                                                                                                                                                                                                                                                                                  |
| 28-26 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                        |
| 25-21 | REGADR   | 0-1Fh   | Register address bits. This field specifies the PHY register to be accessed for this transaction.                                                                                                                                                                                                                                                                                                               |
| 20-16 | PHYADR   | 0-1Fh   | PHY address bits. This field specifies the PHY to be accessed for this transaction.                                                                                                                                                                                                                                                                                                                             |
| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                     |

### 28.4.12 MDIO User PHY Select Register 0 (USERPHYSEL0)

The MDIO user PHY select register 0 (USERPHYSEL0) is shown in [Figure 28-39](#) and described in [Table 28-36](#).

**Figure 28-39. MDIO User PHY Select Register 0 (USERPHYSEL0)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-36. MDIO User PHY Select Register 0 (USERPHYSEL0) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                 |
|------|------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                    |
| 7    | LINKSEL    | 0<br>1 | Link status determination select bit. Default value is 0, which implies that the link status is determined by the MDIO state machine. This is the only option supported on this device.<br>The link status is determined by the MDIO state machine.<br>Not supported.                                       |
| 6    | LINKINTENB | 0<br>1 | Link change interrupt enable. Set to 1 to enable link change interrupts for PHY address specified in PHYADRMON. Link change interrupts are disabled if this bit is cleared to 0.<br>Link change interrupts are disabled.<br>Link change interrupts for PHY address specified in PHYADRMON bits are enabled. |
| 5    | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                    |
| 4-0  | PHYADRMON  | 0-1Fh  | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                           |

### 28.4.13 MDIO User Access Register 1 (USERACCESS1)

The MDIO user access register 1 (USERACCESS1) is shown in [Figure 28-40](#) and described in [Table 28-37](#).

**Figure 28-40. MDIO User Access Register 1 (USERACCESS1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-37. MDIO User Access Register 1 (USERACCESS1) Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | GO       | 0-1     | Go bit. Writing 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS1 are blocked when the GO bit is 1. |
| 30    | WRITE    | 0<br>1  | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.<br>The user command is a read operation.<br>The user command is a write operation.                                                                                                                                                                                            |
| 29    | ACK      | 0-1     | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.                                                                                                                                                                                                                                                                                                                              |
| 28-26 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25-21 | REGADR   | 0-1Fh   | Register address bits. This field specifies the PHY register to be accessed for this transaction.                                                                                                                                                                                                                                                                                                           |
| 20-16 | PHYADR   | 0-1Fh   | PHY address bits. This field specifies the PHY to be accessed for this transaction.                                                                                                                                                                                                                                                                                                                         |
| 15-0  | DATA     | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register.                                                                                                                                                                                                                                                                                                 |

### 28.4.14 MDIO User PHY Select Register 1 (USERPHYSEL1)

The MDIO user PHY select register 1 (USERPHYSEL1) is shown in [Figure 28-41](#) and described in [Table 28-38](#).

**Figure 28-41. MDIO User PHY Select Register 1 (USERPHYSEL1)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-38. MDIO User PHY Select Register 1 (USERPHYSEL1) Field Descriptions**

| Bit  | Field      | Value  | Description                                                                                                                                                                                                                                                                                                                   |
|------|------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved   | 0      | Reserved                                                                                                                                                                                                                                                                                                                      |
| 7    | LINKSEL    | 0<br>1 | Link status determination select bit. Default value is 0, which implies that the link status is determined by the MDIO state machine. This is the only option supported on this device.<br>The link status is determined by the MDIO state machine.<br>Not supported.                                                         |
| 6    | LINKINTENB | 0<br>1 | Link change interrupt enable. Set to 1 to enable link change status interrupts for the PHY address specified in PHYADRMON. Link change interrupts are disabled if this bit is cleared to 0.<br>Link change interrupts are disabled.<br>Link change status interrupts for PHY address specified in PHYADRMON bits are enabled. |
| 5    | Reserved   | 0      | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                                             |
| 4-0  | PHYADRMON  | 0-1Fh  | PHY address whose link status is to be monitored.                                                                                                                                                                                                                                                                             |

## 28.5 EMAC Module Registers

Table 28-39 lists the memory-mapped registers for the EMAC. The base address for these registers is FCF7 8000h.

**Table 28-39. Ethernet Media Access Controller (EMAC) Registers**

| Offset | Acronym           | Register Description                                            | Section                         |
|--------|-------------------|-----------------------------------------------------------------|---------------------------------|
| 0h     | TXREVID           | Transmit Revision ID Register                                   | <a href="#">Section 28.5.1</a>  |
| 4h     | TXCONTROL         | Transmit Control Register                                       | <a href="#">Section 28.5.2</a>  |
| 8h     | TXTEARDOWN        | Transmit Teardown Register                                      | <a href="#">Section 28.5.3</a>  |
| 10h    | RXREVID           | Receive Revision ID Register                                    | <a href="#">Section 28.5.4</a>  |

| 26Ch                                | FRAME65T127       | Transmit and Receive 65 to 127 Octet Frames Register        | <a href="#">Section 28.5.50.28</a> |
| 270h                                | FRAME128T255      | Transmit and Receive 128 to 255 Octet Frames Register       | <a href="#">Section 28.5.50.29</a> |
| 274h                                | FRAME256T511      | Transmit and Receive 256 to 511 Octet Frames Register       | <a href="#">Section 28.5.50.30</a> |
| 278h                                | FRAME512T1023     | Transmit and Receive 512 to 1023 Octet Frames Register      | <a href="#">Section 28.5.50.31</a> |
| 27Ch                                | FRAME1024TUP      | Transmit and Receive 1024 to RXMAXLEN Octet Frames Register | <a href="#">Section 28.5.50.32</a> |
| 280h                                | NETOCTETS         | Network Octet Frames Register                               | <a href="#">Section 28.5.50.33</a> |
| 284h                                | RXSOFOVERRUNS     | Receive FIFO or DMA Start of Frame Overruns Register        | <a href="#">Section 28.5.50.34</a> |
| 288h                                | RXMOFOVERRUNS     | Receive FIFO or DMA Middle of Frame Overruns Register       | <a href="#">Section 28.5.50.35</a> |
| 28Ch                                | RXDMAOVERRUNS     | Receive DMA Overruns Register                               | <a href="#">Section 28.5.50.36</a> |

### 28.5.1 Transmit Revision ID Register (TXREVID)

The transmit revision ID register (TXREVID) is shown in [Figure 28-42](#) and described in [Table 28-40](#).

**Figure 28-42. Transmit Revision ID Register (TXREVID)**

LEGEND: R = Read only; -n = value after reset

**Table 28-40. Transmit Revision ID Register (TXREVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                  |
|------|-------|------------|--------------------------------------------------------------|
| 31-0 | TXREV | 4EC0 020Dh | Transmit module revision<br>Current transmit revision value. |

### 28.5.2 Transmit Control Register (TXCONTROL)

The transmit control register (TXCONTROL) is shown in [Figure 28-43](#) and described in [Table 28-41](#).

**Figure 28-43. Transmit Control Register (TXCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-41. Transmit Control Register (TXCONTROL) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                 |
| 0    | TXEN     | 0     | Transmit enable<br>Transmit is disabled. |
|      |          | 1     | Transmit is enabled.                     |

### 28.5.3 Transmit Teardown Register (TXTEARDOWN)

The transmit teardown register (TXTEARDOWN) is shown in [Figure 28-44](#) and described in [Table 28-42](#).

**Figure 28-44. Transmit Teardown Register (TXTEARDOWN)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-42. Transmit Teardown Register (TXTEARDOWN) Field Descriptions**

| Bit  | Field    | Value                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 28.5.4 Receive Revision ID Register (RXREVID)

The receive revision ID register (RXREVID) is shown in [Figure 28-45](#) and described in [Table 28-43](#).

**Figure 28-45. Receive Revision ID Register (RXREVID)**

LEGEND: R = Read only; -n = value after reset

**Table 28-43. Receive Revision ID Register (RXREVID) Field Descriptions**

| Bit  | Field | Value      | Description                                                                   |
|------|-------|------------|-------------------------------------------------------------------------------|
| 31-0 | RXREV | 4EC0 020Dh | <div>Receive module revision</div> <div>Current receive revision value.</div> |

### 28.5.5 Receive Control Register (RXCONTROL)

The receive control register (RXCONTROL) is shown in [Figure 28-46](#) and described in [Table 28-44](#).

**Figure 28-46. Receive Control Register (RXCONTROL)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-44. Receive Control Register (RXCONTROL) Field Descriptions**

| Bit  | Field    | Value  | Description                                                   |
|------|----------|--------|---------------------------------------------------------------|

### 28.5.7 Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)

The transmit interrupt status (unmasked) register (TXINTSTATRAW) is shown in [Figure 28-48](#) and described in [Table 28-46](#).

**Figure 28-48. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 28-46. Transmit Interrupt Status (Unmasked) Register (TXINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                              |
|------|----------|-------|------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                 |
| 7    | TX7PEND  | 0-1   | TX7PEND raw interrupt read (before mask) |
| 6    | TX6PEND  | 0-1   | TX6PEND raw interrupt read (before mask) |
| 5    | TX5PEND  | 0-1   | TX5PEND raw interrupt read (before mask) |
| 4    | TX4PEND  | 0-1   | TX4PEND raw interrupt read (before mask) |
| 3    | TX3PEND  | 0-1   | TX3PEND raw interrupt read (before mask) |
| 2    | TX2PEND  | 0-1   | TX2PEND raw interrupt read (before mask) |
| 1    | TX1PEND  | 0-1   | TX1PEND raw interrupt read (before mask) |
| 0    | TX0PEND  | 0-1   | TX0PEND raw interrupt read (before mask) |

### 28.5.8 Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)

The transmit interrupt status (masked) register (TXINTSTATMASKED) is shown in [Figure 28-49](#) and described in [Table 28-47](#).

**Figure 28-49. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 28-47. Transmit Interrupt Status (Masked) Register (TXINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                   |
|------|----------|-------|-------------------------------|
| 31-8 | Reserved | 0     | Reserved                      |
| 7    | TX7PEND  | 0-1   | TX7PEND masked interrupt read |
| 6    | TX6PEND  | 0-1   | TX6PEND masked interrupt read |
| 5    | TX5PEND  | 0-1   | TX5PEND masked interrupt read |
| 4    | TX4PEND  | 0-1   | TX4PEND masked interrupt read |
| 3    | TX3PEND  | 0-1   | TX3PEND masked interrupt read |
| 2    | TX2PEND  | 0-1   | TX2PEND masked interrupt read |
| 1    | TX1PEND  | 0-1   | TX1PEND masked interrupt read |
| 0    | TX0PEND  | 0-1   | TX0PEND masked interrupt read |

### 28.5.9 Transmit Interrupt Mask Set Register (TXINTMASKSET)

The transmit interrupt mask set register (TXINTMASKSET) is shown in [Figure 28-50](#) and described in [Table 28-48](#).

**Figure 28-50. Transmit Interrupt Mask Set Register (TXINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 28-48. Transmit Interrupt Mask Set Register (TXINTMASKSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                         |
|------|----------|-------|-----------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                            |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |

### 28.5.10 Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)

The transmit interrupt mask clear register (TXINTMASKCLEAR) is shown in [Figure 28-51](#) and described in [Table 28-49](#).

**Figure 28-51. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-49. Transmit Interrupt Mask Clear Register (TXINTMASKCLEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                            |
|------|----------|-------|--------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved | 0     | Reserved                                                                                               |
| 7    | TX7MASK  | 0-1   | Transmit channel 7 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 6    | TX6MASK  | 0-1   | Transmit channel 6 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 5    | TX5MASK  | 0-1   | Transmit channel 5 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 4    | TX4MASK  | 0-1   | Transmit channel 4 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 3    | TX3MASK  | 0-1   | Transmit channel 3 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 2    | TX2MASK  | 0-1   | Transmit channel 2 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 1    | TX1MASK  | 0-1   | Transmit channel 1 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 0    | TX0MASK  | 0-1   | Transmit channel 0 interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |

### 28.5.11 MAC Input Vector Register (MACINVECTOR)

The MAC input vector register (MACINVECTOR) is shown in [Figure 28-52](#) and described in [Table 28-50](#).

**Figure 28-52. MAC Input Vector Register (MACINVECTOR)**

|              |    |          |          |          |          |        |    |
|--------------|----|----------|----------|----------|----------|--------|----|

### 28.5.14 Receive Interrupt Status (Masked) Register (RXINTSTATMASKED)

The receive interrupt status (masked) register (RXINTSTATMASKED) is shown in [Figure 28-55](#) and described in [Table 28-53](#).

**Figure 28-55. Receive Interrupt Status (Masked) Register (RXINTSTATMASKED)**

| 15    | RX7THRESHMASK | 0-1   | Receive channel 7 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 14    | RX6THRESHMASK | 0-1   | Receive channel 6 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 13    | RX5THRESHMASK | 0-1   | Receive channel 5 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 12    | RX4THRESHMASK | 0-1   | Receive channel 4 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 11    | RX3THRESHMASK | 0-1   | Receive channel 3 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 10    | RX2THRESHMASK | 0-1   | Receive channel 2 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 9     | RX1THRESHMASK | 0-1   | Receive channel 1 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 8     | RX0THRESHMASK | 0-1   | Receive channel 0 threshold mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect. |
| 7     | RX7MASK       | 0-1   | Receive channel 7 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 6     | RX6MASK       | 0-1   | Receive channel 6 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 5     | RX5MASK       | 0-1   | Receive channel 5 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 4     | RX4MASK       | 0-1   | Receive channel 4 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 3     | RX3MASK       | 0-1   | Receive channel 3 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 2     | RX2MASK       | 0-1   | Receive channel 2 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 1     | RX1MASK       | 0-1   | Receive channel 1 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |
| 0     | RX0MASK       | 0-1   | Receive channel 0 mask clear bit. Write 1 to disable interrupt; a write of 0 has no effect.           |

### 28.5.17 MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)

The MAC interrupt status (unmasked) register (MACINTSTATRAW) is shown in [Figure 28-58](#) and described in [Table 28-56](#).

**Figure 28-58. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW)**

LEGEND: R = Read only; -n = value after reset

**Table 28-56. MAC Interrupt Status (Unmasked) Register (MACINTSTATRAW) Field Descriptions**

| Bit  | Field    | Value | Description                                                                |
|------|----------|-------|----------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                   |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); raw interrupt read (before mask).       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); raw interrupt read (before mask). |

### 28.5.18 MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)

The MAC interrupt status (masked) register (MACINTSTATMASKED) is shown in [Figure 28-59](#) and described in [Table 28-57](#).

**Figure 28-59. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED)**

LEGEND: R = Read only; -n = value after reset

**Table 28-57. MAC Interrupt Status (Masked) Register (MACINTSTATMASKED) Field Descriptions**

| Bit  | Field    | Value | Description                                                     |
|------|----------|-------|-----------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                        |
| 1    | HOSTPEND | 0-1   | Host pending interrupt (HOSTPEND); masked interrupt read.       |
| 0    | STATPEND | 0-1   | Statistics pending interrupt (STATPEND); masked interrupt read. |

### 28.5.19 MAC Interrupt Mask Set Register (MACINTMASKSET)

The MAC interrupt mask set register (MACINTMASKSET) is shown in [Figure 28-60](#) and described in [Table 28-58](#).

**Figure 28-60. MAC Interrupt Mask Set Register (MACINTMASKSET)**

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set (writing a 0 has no effect); -n = value after reset

**Table 28-58. MAC Interrupt Mask Set Register (MACINTMASKSET) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                 |
|------|----------|-------|---------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                    |
| 1    | HOSTMASK | 0-1   | Host error interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |
| 0    | STATMASK | 0-1   | Statistics interrupt mask set bit. Write 1 to enable interrupt, a write of 0 has no effect. |

### 28.5.20 MAC Interrupt Mask Clear Register (MACINTMASKCLEAR)

The MAC interrupt mask clear register (MACINTMASKCLEAR) is shown in [Figure 28-61](#) and described in [Table 28-59](#).

**Figure 28-61. MAC Interrupt Mask Clear Register (MACINTMASKCLEAR)**

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear (writing a 0 has no effect); -n = value after reset

**Table 28-59. MAC Interrupt Mask Clear Register (MACINTMASKCLEAR) Field Descriptions**

| Bit  | Field    | Value | Description                                                                                    |
|------|----------|-------|------------------------------------------------------------------------------------------------|
| 31-2 | Reserved | 0     | Reserved                                                                                       |
| 1    | HOSTMASK | 0-1   | Host error interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |
| 0    | STATMASK | 0-1   | Statistics interrupt mask clear bit. Write 1 to disable interrupt, a write of 0 has no effect. |

### 28.5.21 Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE)

The receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is shown in [Figure 28-62](#) and described in [Table 28-60](#).

**Figure 28-62. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE)**

| 15-0  | RXBUFFEROFFSET | 0-FFFFh | Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

### 28.5.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in [Figure 28-67](#) and described in [Table 28-65](#).

**Figure 28-67. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-65. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions**

| Bit  | Field          | Value | Description                                                                                                                                                                                |
|------|----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved       | 0     | Reserved                                                                                                                                                                                   |
| 7-0  | RXFILTERTHRESH | 0-FFh | Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired. |

### 28.5.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX $n$ FLOWTHRESH) is shown in [Figure 28-68](#) and described in [Table 28-66](#).

**Figure 28-68. Receive Channel  $n$  Flow Control Threshold Register (RX $n$ FLOWTHRESH)**

LEGEND: R/W = Read/Write; R = Read only; - $n$  = value after reset

**Table 28-66. Receive Channel  $n$  Flow Control Threshold Register (RX $n$ FLOWTHRESH) Field Descriptions**

| Bit  | Field             | Value | Description                                                                                                                                |
|------|-------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 31-8 | Reserved          | 0     | Reserved                                                                                                                                   |
| 7-0  | RX $n$ FLOWTHRESH | 0-FFh | Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel $n$ (when enabled). |

### 28.5.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX $n$ FREEBUFFER) is shown in [Figure 28-69](#) and described in [Table 28-67](#).

**Figure 28-69. Receive Channel  $n$  Free Buffer Count Register (RX $n$ FREEBUFFER)**

LEGEND: R = Read only; WI = Write to increment; - $n$  = value after reset

**Table 28-67. Receive Channel  $n$  Free Buffer Count Register (RX $n$ FREEBUFFER) Field Descriptions**

| Bit   | Field          | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 15-0  | RX $n$ FREEBUF | 0-FFh | Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX $n$ FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow.<br><br>If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing. |

## 28.5.29 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in [Figure 28-70](#) and described in [Table 28-68](#).

**Figure 28-70. MAC Control Register (MACCONTROL)**

**Table 28-68. MAC Control Register (MACCONTROL) Field Descriptions (continued)**

| Bit | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|----------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | GMIEN          | 0<br>1 | GMII enable bit. This bit must be set before the MAC transmits or receives data in any of the supported interface modes. (for instance, MII, RMII). This bit does not select the interface mode but rather holds or releases the MAC TX and RX state machines from reset.<br>The MAC RX and TX state machines are held in reset.<br>The MAC RX and TX state machines are released from reset and transmit and receive are enabled.                                                                             |
| 4   | TXFLOWEN       | 0<br>1 | Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of this bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory.<br>Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon.<br>Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon. |
| 3   | RXBUFFERFLOWEN | 0<br>1 | Receive buffer flow control enable bit<br>Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.<br>Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.                                                                                       |
| 2   | Reserved       | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1   | LOOPBACK       | 0<br>1 | Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit. The loopback bit should be changed only when GMIEN bit is deasserted.<br>Loopback mode is disabled.<br>Loopback mode is enabled.                                                                                                                                                                                                                                                                           |
| 0   | FULLDUPLEX     | 0<br>1 | Full duplex mode.<br>Half-duplex mode is enabled.<br>Full-duplex mode is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 28.5.30 MAC Status Register (MACSTATUS)

The MAC status register (MACSTATUS) is shown in [Figure 28-71](#) and described in [Table 28-69](#).

**Figure 28-71. MAC Status Register (MACSTATUS)**

### Table 28-71. FIFO Control Register (FIFOCONTROL) Field Descriptions

| Bit  | Field        | Value | Description                                                                                                                                                                                                                                                                                                                      |
|------|--------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-2 | Reserved     | 0     | Reserved                                                                                                                                                                                                                                                                                                                         |
| 1-0  | TXCELLTHRESH |       | Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values. |
|      |              | 0-1h  | Not a valid value.                                                                                                                                                                                                                                                                                                               |
|      |              | 2h    | Two 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                    |
|      |              | 3h    | Three 64-byte packet cells required to be in the transmit FIFO.                                                                                                                                                                                                                                                                  |

### 28.5.33 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in [Figure 28-74](#) and described in [Table 28-72](#).

**Figure 28-74. MAC Configuration Register (MACCONFIG)**

LEGEND: R = Read only; -n = value after reset

**Table 28-72. MAC Configuration Register (MACCONFIG) Field Descriptions**

| Bit   | Field       | Value | Description                                                                        |
|-------|-------------|-------|------------------------------------------------------------------------------------|
| 31-24 | TXCELLDEPTH | 3h    | Transmit cell depth. These bits indicate the number of cells in the transmit FIFO. |
| 23-16 | RXCELLDEPTH | 3h    | Receive cell depth. These bits indicate the number of cells in the receive FIFO.   |
| 15-8  | ADDRESSTYPE | 2h    | Address type                                                                       |
| 7-0   | MACCFIG     | 2h    | MAC configuration value                                                            |

### 28.5.34 Soft Reset Register (SOFTRESET)

The soft reset register (SOFTRESET) is shown in [Figure 28-75](#) and described in [Table 28-73](#).

**Figure 28-75. Soft Reset Register (SOFTRESET)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-73. Soft Reset Register (SOFTRESET) Field Descriptions**

| Bit  | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved  | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                          |
| 0    | SOFTRESET | 0     | Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet occurred. If a 0 is read, then a reset has occurred. |
|      |           | 0     | A software reset has not occurred.                                                                                                                                                                                                                                                                                                                                                                |
|      |           | 1     | A software reset has occurred.                                                                                                                                                                                                                                                                                                                                                                    |

### 28.5.35 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in [Figure 28-76](#) and described in [Table 28-74](#).

**Figure 28-76. MAC Source Address Low Bytes Register (MACSRCADDRLO)**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 28-74. MAC Source Address Low Bytes Register (MACSRCADDRLO) Field Descriptions**

| Bit   | Field       | Value | Description                                |
|-------|-------------|-------|--------------------------------------------|
| 31-16 | Reserved    | 0     | Reserved                                   |
| 15-8  | MACSRCADDR0 | 0-FFh | MAC source address lower 8-0 bits (byte 0) |
| 7-0   | MACSRCADDR1 | 0-FFh | MAC source address bits 15-8 (byte 1)      |

### 28.5.36 MAC Source Address High Bytes Register (MACSRCADDRHI)

The MAC source address high bytes register (MACSRCADDRHI) is shown in [Figure 28-77](#) and described in [Table 28-75](#).

**Figure 28-77. MAC Source Address High Bytes Register (MACSRCADDRHI)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 28-75. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions**

| Bit   | Field       | Value | Description                            |
|-------|-------------|-------|----------------------------------------|
| 31-24 | MACSRCADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2) |
| 23-16 | MACSRCADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3) |
| 15-8  | MACSRCADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4) |
| 7-0   | MACSRCADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5) |

### 28.5.37 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash\_fun) from the 48-bit destination address (DA) as follows:

Hash\_fun(0)=DA(0) XOR DA(6) XOR DA(12) XOR DA(18) XOR DA(24) XOR DA(30) XOR DA(36) XOR DA(42);

Hash\_fun(1)=DA(1) XOR DA(7) XOR DA(13) XOR DA(19) XOR DA(25) XOR DA(31) XOR DA(37) XOR DA(43);

Hash\_fun(2)=DA(2) XOR DA(8) XOR DA(14) XOR DA(20) XOR DA(26) XOR DA(32) XOR DA(38) XOR DA(44);

Hash\_fun(3)=DA(3) XOR DA(9) XOR DA(15) XOR DA(21) XOR DA(27) XOR DA(33) XOR DA(39) XOR DA(45);

Hash\_fun(4)=DA(4) XOR DA(10) XOR DA(16) XOR DA(22) XOR DA(28) XOR DA(34) XOR DA(40) XOR DA(46);

Hash\_fun(5)=DA(5) XOR DA(11) XOR DA(17) XOR DA(23) XOR DA(29) XOR DA(35) XOR DA(41) XOR DA(47);

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in [Figure 28-78](#) and described in [Table 28-76](#).

**Figure 28-78. MAC Hash Address Register 1 (MACHASH1)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 28-76. MAC Hash Address Register 1 (MACHASH1) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH1 | 0-FFFF FFFFh | Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 28.5.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in [Figure 28-79](#) and described in [Table 28-77](#).

**Figure 28-79. MAC Hash Address Register 2 (MACHASH2)**

LEGEND: R/W = Read/Write; -n = value after reset

**Table 28-77. MAC Hash Address Register 2 (MACHASH2) Field Descriptions**

| Bit  | Field    | Value        | Description                                                                                                                                                                   |
|------|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | MACHASH2 | 0-FFFF FFFFh | Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

### 28.5.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in [Figure 28-80](#) and described in [Table 28-78](#).

**Figure 28-80. Back Off Random Number Generator Test Register (BOFFTEST)**

|           |  |          |    |           |    |
|-----------|--|----------|----|-----------|----|
| 31        |  | 26       | 25 |           | 16 |
| Reserved  |  |          |    | RNDNUM    |    |
| R-0       |  |          |    | R-0       |    |
| 15        |  | 12       | 11 | 10        | 9  |
| COLLCOUNT |  | Reserved |    | TXBACKOFF |    |
| R-0       |  | R-0      |    | R-0       |    |

LEGEND: R = Read only; -n = value after reset

**Table 28-78. Back Off Test Register (BOFFTEST) Field Descriptions**

| Bit   | Field     | Value  | Description                                                                                                                                                                                                                                           |
|-------|-----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-26 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 25-16 | RNDNUM    | 0-3FFh | Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLLCOUNT | 0-Fh   | Collision count. These bits indicate the number of collisions the current frame has experienced.                                                                                                                                                      |
| 11-10 | Reserved  | 0      | Reserved                                                                                                                                                                                                                                              |
| 9-0   | TXBACKOFF | 0-3FFh | Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.  |

### 28.5.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in [Figure 28-81](#) and described in [Table 28-79](#).

**Figure 28-81. Transmit Pacing Algorithm Test Register (TPACETEST)**

|          |  |  |   |         |    |

| 31-5 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4-0  | PACEVAL  | 0-1Fh | Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth. |

### 28.5.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in [Figure 28-82](#) and described in [Table 28-80](#).

**Figure 28-82. Receive Pause Timer Register (RXPAUSE)**

|-------|------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16 | Reserved   | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 15-0  | PAUSETIMER | 0-FFh | Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated. |

### 28.5.42 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in [Figure 28-83](#) and described in [Table 28-81](#).

**Figure 28-83. Transmit Pause Timer Register (TXPAUSE)**

| R/W-x    |    | R/W-x    |    |

LEGEND: R/W = Read/Write; -x = value is indeterminate after reset

**Table 28-83. MAC Address High Bytes Register (MACADDRHI) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                               |
|-------|----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | MACADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2)                                                                                                                                    |
| 23-16 | MACADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3)                                                                                                                                    |
| 15-8  | MACADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4)                                                                                                                                    |
| 7-0   | MACADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table. |

### 28.5.45 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in [Figure 28-86](#) and described in [Table 28-84](#).

**Figure 28-86. MAC Index Register (MACINDEX)**

|------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-3 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2-0  | MACINDEX | 0-7h  | MAC address index. All eight addresses share the upper 40 bits. Only the lower byte is unique for each address. An address is written by first writing the address number (channel) into the MACINDEX register. The upper 32 bits of the address are then written to the MACADDRHI register, which is followed by writing the lower 16 bits of the address to the MACADDRLO register. Since all eight addresses share the upper 40 bits of the address, the MACADDRHI register only needs to be written the first time. |

### 28.5.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX $n$ HDP) is shown in [Figure 28-87](#) and described in [Table 28-85](#).

**Figure 28-87. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 28-85. Transmit Channel  $n$  DMA Head Descriptor Pointer Register (TX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                         |
|------|------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ HDP | 0-FFFF FFFFh | Transmit channel $n$ DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 28.5.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX $n$ HDP) is shown in [Figure 28-88](#) and described in [Table 28-86](#).

**Figure 28-88. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 28-86. Receive Channel  $n$  DMA Head Descriptor Pointer Register (RX $n$ HDP)  
Field Descriptions**

| Bit  | Field      | Value        | Description                                                                                                                                                                                                                                                                                                                                            |
|------|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RX $n$ HDP | 0-FFFF FFFFh | Receive channel $n$ DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

### 28.5.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TX $n$ CP) is shown in [Figure 28-89](#) and described in [Table 28-87](#).

**Figure 28-89. Transmit Channel  $n$  Completion Pointer Register (TX $n$ CP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 28-87. Transmit Channel  $n$  Completion Pointer Register (TX $n$ CP) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                                                                                                                                           |
|------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | TX $n$ CP | 0-FFFF FFFFh | Transmit channel $n$ completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

### 28.5.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RX $n$ CP) is shown in [Figure 28-90](#) and described in [Table 28-88](#).

**Figure 28-90. Receive Channel  $n$  Completion Pointer Register (RX $n$ CP)**

LEGEND: R/W = Read/Write; - $n$  = value after reset; -x = value is indeterminate after reset

**Table 28-88. Receive Channel  $n$  Completion Pointer Register (RX $n$ CP) Field Descriptions**

| Bit  | Field     | Value        | Description                                                                                                                                                                                                                                                          |
|------|-----------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | RX $n$ CP | 0-FFFF FFFFh | Receive channel $n$ completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

## 28.5.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of reset. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see [Figure 28-91](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

**Figure 28-91. Statistics Register**

|    |        |   |
|----|--------|---|
| 31 |        | 0 |
|    | COUNT  |   |
|    | R/WD-0 |   |

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

### 28.5.50.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 28.5.50.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 28.5.50.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### 28.5.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMACs MII\_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

### 28.5.50.7 Receive Oversized Frames Register (RXOVERSIZED)

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.8 Receive Jabber Frames Register (RXJABBER)

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.9 Receive Undersized Frames Register (RXUNDERSIZED)

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.10 Receive Frame Fragments Register (RXFRAGMENTS)

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

### 28.5.50.11 Filtered Receive Frames Register (RXFILTERED)

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

#### **28.5.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)**

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RXnFLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RXnFREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### **28.5.50.13 Receive Octet Frames Register (RXOCTETS)**

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 28.2.6.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

#### **28.5.50.14 Good Transmit Frames Register (TXGOODFRAMES)**

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### 28.5.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### 28.5.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES)

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

#### 28.5.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

#### 28.5.50.18 Deferred Transmit Frames Register (TXDEFERRED)

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

#### 28.5.50.19 Transmit Collision Frames Register (TXCOLLISION)

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

**28.5.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL)**

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

**28.5.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)**

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

**28.5.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)**

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

**28.5.50.23 Transmit Late Collision Frames Register (TXLATECOLL)**

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

**28.5.50.24 Transmit Underrun Error Register (TXUNDERRUN)**

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

**28.5.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)**

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

**28.5.50.26 Transmit Octet Frames Register (TXOCTETS)**

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

**28.5.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64)**

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

**28.5.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)**

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

**28.5.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)**

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

**28.5.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)**

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

**28.5.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)**

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

**28.5.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)**

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

**28.5.50.33 Network Octet Frames Register (NETOCTETS)**

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

**28.5.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**28.5.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)**

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

**28.5.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS)**

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

## ***Universal Serial Bus (USB)***

---

---

---

This chapter describes the universal serial bus (USB) controller on the microcontroller.

| Topic                                   | Page        |
|-----------------------------------------|-------------|

| <b>29.2 USB Host Controller .....</b>   | <b>1533</b> |
| <b>29.3 USB Device Controller .....</b> | <b>1560</b> |
| <b>29.4 USB Connectivity.....</b>       | <b>1654</b> |

## 29.1 Overview

The microcontroller provides several varieties of USB functionality, including:

- USB host: device provides a two-port *USB Specification Revision 1.1* - compliant host controller, which is based on the *OHCI Specification for USB Release 1.0a*
- USB device: device provides a full-speed USB device
- Support for up to 2 active simultaneous ports (1 Function and 1 Host, or 2 Hosts)

## 29.2 USB Host Controller

The USB host controller (HC) is a two-port controller that communicates with USB devices at the USB low-speed (1.5M bit-per-second maximum) and full-speed (12M bit-per-second maximum) data rates. It is compatible with the *Universal Serial Bus Specification Revision 2.0* and the *Open HCI—Open Host Controller Interface Specification for USB*, Release 1.0a, available through the Compaq Computer Corporation web site, and hereafter called the *OHCI Specification for USB*. It is assumed that users of the USB host controller are already familiar with the *USB Specification* and *OHCI Specification for USB*.

The USB host controller implements the register set and makes use of the memory data structures defined in the *OHCI Specification for USB*. These registers and data structures are the mechanism by which a USB host controller driver software package can control the USB host controller. The *OHCI Specification for USB* also defines how the USB host controller implementation must interact with those registers and data structures in system memory. The device CPU accesses these registers via the module's peripheral bus.

To reduce processor software and interrupt overhead, the USB host controller generates USB traffic based on data structures and data buffers stored in system memory. The USB host controller accesses these data structures without direct intervention by the processor using the master access (bus transaction initiator) port. These data structures and data buffers can be located in internal or external RAM.

The USB host controller provides an interrupt to the Vectored Interrupt Manager (VIM) to signal certain hardware events to the host controller driver software.

### 29.2.1 USB Open Host Controller Interface Functionality

#### 29.2.1.1 OHCI Controller Overview

The *Open HCI—Open Host Controller Interface Specification for USB*, Release 1.0a, defines a set of registers and data structures stored in system memory that define how a USB host controller interfaces to system software. This specification, in conjunction with the *Universal Serial Bus Specification Version 2.0*, defines most of the USB functionality that the USB host controller provides.

The *OHCI Specification for USB* focuses on two main aspects of the hardware implementation of a USB host controller: its register set and the memory data structures that define the activity to appear on the USB bus. Also discussed are issues such as interrupt generation, USB host controller state, USB frame management, and the methods that the hardware must use to process the lists of data structures in system memory.

This document does not duplicate the information presented in the *OHCI Specification for USB* or the *USB Specification*. USB host controller users can refer to the *USB Specification* and the *OHCI Specification for USB* for detailed discussions of USB requirements and OHCI controller operation.

## 29.2.2 USB Host Controller Differences From OHCI Specification for USB

The USB host controller implementation does not implement every aspect of the functionality defined in the *OHCI Specification for USB*. The differences focus on the OHCI ownership change interrupt. Other restrictions are imposed by the effects of the device pin multiplexing options.

### 29.2.2.1 Top-Level Pin Multiplexing and OHCI Registers

The RM4x microcontroller supports two USB Host ports and one USB Device port. The USB device port interface signals are multiplexed with the second USB Host port interface signals. All USB interface signals are also multiplexed with other functions on the RM4x microcontrollers. The configuration of these multiplexors is done by configuring the I/O Multiplexing Module control registers. Refer to the *I/O Multiplexing and Control Module (IOMM)* chapter for more information on the sequence for configuring these control registers.

The OHCI RHDESCRIPTORA register always reports two available USB host ports, regardless of the top-level pin multiplexing settings.

**Table 29-1. USB Host / Device Interface Signal Multiplexing and Control**

| USB Host / Device Interface Signal Name | Control for Selecting USB Host Signal | Control for Selecting USB Device Signal |
|-----------------------------------------|---------------------------------------|-----------------------------------------|
| USB1.OVERCURRENT                        | PINMMR14 [7:0] = 08h                  | -                                       |
| USB1.RCV                                | PINMMR13 [31:24] = 08h                | -                                       |
| USB1.VM                                 | PINMMR12 [31:24] = 08h                | -                                       |
| USB1.VP                                 | PINMMR12 [23:16] = 08h                | -                                       |
| USB1.PORTPOWER                          | PINMMR21 [15:8] = 02h                 | -                                       |
| USB1.SPEED                              | PINMMR19 [15:8] = 04h                 | -                                       |
| USB1.SUSPEND                            | PINMMR20 [23:16] = 08h                | -                                       |
| USB1.TXDAT                              | PINMMR18 [31:24] = 02h                | -                                       |
| USB1.TXEN                               | PINMMR17 [7:0] = 04h                  | -                                       |
| USB1.TXSE0                              | PINMMR18 [15:8] = 02h                 | -                                       |
| USB2.OVERCURRENT / USB_FUNC.VBUSI       | PINMMR1 [15:8] = 08h                  | PINMMR1 [15:8] = 10h                    |
| USB2.RCV / USB_FUNC.RXDI                | PINMMR0 [7:0] = 02h                   | PINMMR0 [7:0] = 04h                     |
| USB2.VM / USB_FUNC.RXDMI                | PINMMR1 [7:0] = 02h                   | PINMMR1 [7:0] = 04h                     |
| USB2.VP / USB_FUNC.RXDPI                | PINMMR0 [15:8] = 02h                  | PINMMR0 [15:8] = 04h                    |
| USB2.PORTPOWER / USB_FUNC.GZO           | PINMMR6 [7:0] = 02h                   | PINMMR6 [7:0] = 04h                     |
| USB2.SPEED / USB_FUNC.PUENON            | PINMMR4 [31:24] = 04h                 | PINMMR4 [31:24] = 08h                   |
| USB2.SUSPEND / USB_FUNC.SUSPENDO        | PINMMR6 [23:16] = 04h                 | PINMMR6 [23:16] = 08h                   |
| USB2.TXDAT / USB_FUNC.TXDO              | PINMMR2 [7:0] = 02h                   | PINMMR2 [7:0] = 04h                     |
| USB2.TXEN / USB_FUNC.PUENO              | PINMMR4 [23:16] = 04h                 | PINMMR4 [23:16] = 08h                   |
| USB2.TXSE0 / USB_FUNC.SE0O              | PINMMR3 [15:8] = 02h                  | PINMMR3 [15:8] = 04h                    |

### 29.2.2.2 No Ownership Change Interrupt

The USB host controller does not implement the OHCI ownership change interrupt.

## 29.2.3 Implementation of OHCI Specification for USB

### 29.2.3.1 Isochronous Transmit Descriptor (TD) OFFSETX/PSWX Values

The USB host controller implements the *OHCI Specification for USB* optional feature of checking isochronous OFFSETX/PSWX values. If either OFFSETX or OFFSET(X+1) does not have a condition code of *Not Accessed*, or if the OFFSET(X+1) value is not greater than or equal to OFFSETX, then an unrecoverable error is reported. Unrecoverable errors issued for these reasons do not cause an update of the HOSTUEADDR, HOSTUESTATUS, or HOSTTIMEOUTCTRL registers.

### 29.2.3.2 USB Host Controller Endpoint Descriptor (ED) List Head Pointers

The *OHCI Specification for USB* provides a specific sequence of operations for the host controller driver to perform when setting up the host controller. Failure to follow that sequence can result in malfunction. As a specific example, the HCCONTROLHEADED and HCBULKHEADED pointer registers and the 32 HCCAINERRUPTABLE pointers must all point to valid physical addresses of valid endpoint descriptors.

The USB host controller does not check HCCONTROLHEADED registers, HCBULKHEADED registers, or the values in the 32 HCCAINERRUPTABLE pointers before using them to access EDs. If any of these pointers are NULL when the corresponding list enable bit is set, the USB host controller attempts to access using the physical address of 0, which causes an unrecoverable error to be signaled. HOSTUEADDR, HOSTUESTATUS, and HOSTTIMEOUTCTRL registers are updated in this case.

### 29.2.3.3 OHCI USB Suspend State

The USB host controller ignores upstream traffic from downstream devices for about 3 ms after the host controller state (HCCONTROL.HCFS) changes from USB resume state to USB operational state. If any TDs cause generation of downstream packets during that time, the downstream packets are sent, but any response provided by the downstream device is ignored. Any such TDs are aborted with completion codes marked as *Device Not Responding*. TDs on any of the lists (periodic, control, bulk, and isochronous) can cause such an occurrence.

The USB specification requires that system software must provide a 10-ms resume recovery time ( $T_{RSMRCY}$ ) after a bus segment transitions from resume signaling to normal operational mode. During that time, only start of frame packets are to be sent on the bus segment. It is recommended that system software disable all list enable bits (HCCONTROL.PLE, HCCONTROL.IE, HCCONTROL.CLE, and HCCONTROL.BLE) and then wait for at least 1 ms before setting the host controller into USB suspend state (via HCCONTROL.HCFS). When restoring from suspend, system software must set the host controller into USB resume state, and wait for the host controller to transition into USB operational state. System software must then wait 10 ms before enabling the host controller list enable bits.

When the host controller has been placed into the USB suspend state under software control, but is brought out by a remote wake-up, system software must monitor the HCRHPORTSTATUS[x].PSS and HCRHPORTSTATUS[x].PSSC bits. The HCRHPORTSTATUS[x].PSS bit changes to 0 only after completion of resume signaling on the bus segment completes and completion of the 3-ms period where packets from downstream devices are ignored.

When using port-specific suspend, it is not necessary to disable the host controller lists so long as there are no active EDs and TDs directed toward devices that are downstream of the suspended port. For port-specific suspend operations, the host controller does not issue a root hub status change interrupt with the HCRHPORTSTATUS[n].PSSC bit = 1 and HCRHPORTSTATUS[n].PSS = 0 until after the approximately 3-ms delay after resume signaling completes.

When using port-specific suspend, system software must ensure that there are no active EDs for devices that are downstream of the suspended port before setting the port into suspend mode. While the port is in suspend or being resumed, system software must not enable any EDs for any devices downstream of the suspended port. Once the root hub status change interrupt occurs as a result of the suspended port PSS bit changing to 0, EDs can be enabled for devices downstream of the port that is now operational.

## 29.2.4 USB Host Controller Registers

Most of the host controller (HC) registers are the OHCI operational registers, which are defined by the *OHCI Specification for USB*. Four additional registers not specified by the *OHCI Specification for USB* provide additional information about the USB host controller state. USB host controller registers can be accessed in user and supervisor modes.

The USB host controller registers are listed in [Table 29-2](#). [Section 29.2.4.1](#) through [Section 29.2.4.27](#) describe specific register bits. The base address for the USB Host controller registers is FCF7 8B00h.

**Table 29-2. USB Host Controller Registers**

| Address    | Register <sup>(1)</sup> | Description                                                                     | Section                           |
|------------|-------------------------|---------------------------------------------------------------------------------|-----------------------------------|
| FCF7 8B00h | HCREVISION              | OHCI revision number                                                            | <a href="#">Section 29.2.4.1</a>  |
| FCF7 8B04h | HCCONTROL               | HC operating mode                                                               | <a href="#">Section 29.2.4.2</a>  |

### 29.2.4.2 HC Operating Mode Register (HCCONTROL)

The HC operating mode register ([Figure 29-2](#)) controls the operating mode of the USB host controller.

| 3     | OCR      | 0-1   | Ownership change request<br>This bit is set by the host controller driver to gain ownership of the host controller.<br>The device does not support SMI interrupts, so no ownership change interrupt occurs.                                                                                                                                                                                                                                   |
| 2     | BLF      | 0-1   | Bulk list filled<br>The host controller driver must set this bit if it modifies the bulk list to include new TDs. If HCBULKCURRENTED is 0, the USB host controller does not begin processing bulk list EDs unless this bit is set. When the USB host controller sees this bit set and begins processing the bulk list, it clears this bit.                                                                                                    |
| 1     | CLF      | 0-1   | Control list filled<br>The host controller driver must set this bit if it modifies the control list to include new TDs. If HCCONTROLHEADED is 0, the USB host controller does not begin processing control list EDs unless this bit is set. When the USB host controller sees this bit set and begins processing the control list, it clears this bit.                                                                                        |
| 0     | HCR      | 0-1   | Host controller reset. Write of 0 has no effect. Value of 1 initiates a software reset of the USB host controller. This transitions the USB host controller to the USB suspend state. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this bit returns a 0. A write of 1 to this bit does not reset the root hub and does not signal USB reset to downstream USB functions. |

#### 29.2.4.4 HC Interrupt Status Register (HCINTERRUPTSTATUS)

The HC interrupt status register reports the status of the USB host controller internal interrupt sources.

**Figure 29-4. HC Interrupt Status Register (HCINTERRUPTSTATUS) [address = FCF78B0Ch]**

### 29.2.4.5 HC Interrupt Enable Register (HCINTERRUPTENABLE)

The HC interrupt enable register (Figure 29-5) enables various OHCI interrupt sources to generate interrupts to the device level 2 interrupt handler.

**Figure 29-5. HC Interrupt Enable Register (HCINTERRUPTENABLE) [address = FCF78B10h]**

Frame number automatically rolls over from FFFFh to 0.<br>After frame number is incremented, its new value is written to the HCCA and the USB host controller sets the SOF interrupt status bit and begins processing the ED lists. |

### 29.2.4.17 HC Periodic Start Register (HCPERIODICSTART)

The HC periodic start register defines the position within the USB frame where EDs on the periodic list have priority over EDs on the bulk and control lists.

**Figure 29-17. HC Periodic Start Register (HCPERIODICSTART) [address = FCF78B40h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

**Table 29-19. HC Periodic Start Register (HCPERIODICSTART) Bit Field Descriptions**

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                  |
|-------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 13-0  | PS       | 0-3FFFh | Periodic start<br>The host controller driver must program this value to be about 10% less than the frame interval field value so that control and bulk EDs have priority for the first 10% of the frame; then periodic EDs have priority for the remaining 90% of the frame. |

#### 29.2.4.18 HC Low-Speed Threshold Register (HCLSTHRESHOLD)

The HC low-speed threshold register defines the latest time in a frame that the USB host controller can begin a low-speed packet.

**Figure 29-18. HC Low-Speed Threshold Register (HCLSTHRESHOLD) [address = FCF78B44h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

### Table 29-20. HC Low-Speed Threshold Register (HCLSTHRESHOLD) Bit Field Descriptions

| Bit   | Field    | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-14 | Reserved | 0       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 13-0  | LST      | 0-3FFFh | <p>Low-speed threshold</p> <p>This field defines the number of full-speed bit times in the frame after which the USB host controller cannot start an 8-byte low-speed packet. The USB host controller only begins a low-speed transaction if the frame remaining field is greater than the low-speed threshold.</p> <p>The host controller driver must set this field to a value that ensures that an 8-byte low-speed TD completes before the end of the frame. When set, the host controller driver must not change the value.</p> |

#### 29.2.4.19 HC Root Hub A Register (HCRHDESCRIPTORA)

The HC root hub A register defines several aspects of the USB host controller root hub functionality.

**Figure 29-19. HC Root Hub A Register (HCRHDESCRIPTORA) [address = FCF78B48h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

### Table 29-21. HC Root Hub A Register (HCRHDESCRIPTORA) Field Descriptions

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24 | POTPG    | 0-FFh | <p>Power-on to power-good time</p> <p>This field defines the minimum amount of time (2 ms × POTPG) between the USB host controller turning on power to a downstream port and when the USB host can access the downstream device. The default value is 0x2, so that the time is 4 ms.</p> <p>This field has no effect on USB host controller operation. After turning on power to a port, the USB host controller driver must delay the amount of time implied by POTPG before attempting to reset an attached downstream device.</p> <p>The required amount of time is system implementation-specific and must be calculated based on the amount of time the VBUS supply takes to provide valid VBUS to a worst-case downstream USB function controller.</p> <p>The implementation-specific value must be computed and then written to this register before the USB host controller driver is initialized.</p> |
| 23-13 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 12  | NOCP  | 0<br>1 | No overcurrent protection<br>When 0, the USB Host ports support over-current protection inputs. The USB Host ports must not be in the Reset state for the over-current protection inputs to take effect.<br>When 1, this bit indicates that the USB host controller does not implement overcurrent protection inputs. This bit defaults to 1 and can be cleared by the application software.                                                                                                                                                                                                                         |
| 11  | OCPM  | 0<br>1 | Overcurrent protection mode<br>Over-current status is reported collectively for all downstream ports. This is the default value.<br>Over-current status is reported on a per-port basis.<br>This field is valid only if the NoOverCurrentProtection bit is cleared.                                                                                                                                                                                                                                                                                                                                                  |
| 10  | DT    | 0      | Device type<br>This bit is always 0, which indicates that the USB host controller implemented is not a compound device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 9   | NPS   | 0<br>1 | No power switching<br>Indicates that VBUS power switching is supported and is either per-port or all-port switched per the power switching mode field.<br>Indicates that VBUS power switching is not supported and that power is available to all downstream ports when the USB host controller is powered. This is the default value.<br><b>The RM4x microcontroller USB Host ports support over-current protection inputs and automatic power switching upon indication of an over-current condition. The USB Host ports must not be in the Reset state for the over-current protection inputs to take effect.</b> |
| 8   | PSM   | 0<br>1 | Power switching mode<br>Indicates that all ports are powered at the same time. This is the default value.<br>Indicates that each port is powered individually. This mode allows port power to be controlled by either the global switch or per-port switching.<br>If the PortPowerControlMask (PPCM) bit in the HC Root Hub B Register (HCRHDESCRIPTORB) is set, the USB host port only responds to port power commands (Set/ClearPortPower). If the port mask is cleared, then the USB host port is controlled by the global power switch (Set/ClearGlobalPower).                                                   |
| 7-0 | NDP   | 2h     | Number of downstream ports<br>This register defaults to 2 to indicate two downstream ports.<br>The USB signal multiplexing mode and top-level pin multiplexing features can place the device in a mode where 0, 1, or 2 of the USB host controller downstream ports are usable. This register reports two ports, regardless of top-level pin multiplexing mode.                                                                                                                                                                                                                                                      |

### 29.2.4.20 HC Root Hub B Register (HCRHDESCRIPTORB)

The HC root hub B register defines several aspects of the USB host controller root hub functionality.

| 4   | PRS/SPR  | <p>0 Write of 0 has no effect.</p> <p>1 Write of 1 to this bit sets the port 0 port reset status bit and causes the USB host controller to begin signaling USB reset to port 0.</p>                                                                                                                                                                                           | <p>Port 0 port reset status/set port reset</p> <p>When read as 1, indicates that port 0 is signaling the USB reset. When read as 0, USB reset is not being sent to port 0.</p>                                                                                                                                                                                                                                            |
| 3   | POCI/CSS | <p>0 Write of 0 has no effect.</p> <p>1 Write of 1 to this bit when port 0 port suspend status is 1 causes resume signaling on port 0. A write of 1 when port 0 port suspend status is 0 has no effect.</p>                                                                                                                                                                   | <p>Port 0 port overcurrent indicator/clear suspend status</p> <p>When read as 1, indicates a port 0 port overcurrent condition has occurred. When 0, no port 0 port overcurrent condition has occurred.</p>                                                                                                                                                                                                               |
| 2   | PSS/SPS  | <p>0 Write of 0 has no effect.</p> <p>1 If port 0 current connect status is 1, a write of 1 to this bit sets the port 0 port suspend status bit and places port 0 in USB suspend state. If current connect status is 0, a write of 1 instead sets connect status change to inform the USB host controller driver software of an attempt to suspend a disconnected device.</p> | <p>Port 0 port suspend status/set port suspend</p> <p>When read as 0, indicates that port 0 is not in the USB suspend state. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence.</p> <p>When read as 1, indicates that port 0 is in the USB suspend state or is in the resume sequence.</p>                                                            |
| 1   | PES/SPE  | <p>0 Write of 0 has no effect.</p> <p>1 Write of 1 to this bit when port 0 current connect status is 1 sets the port 0 port enable status bit. A write of 1 when port 0 current connect status is 0 has no effect.</p>                                                                                                                                                        | <p>Port 0 port enable status/set port enable</p> <p>When read as 0, this bit indicates that port 0 is not enabled.</p> <p>When read as 1, indicates that port 0 is enabled. This bit is automatically set at completion of port 0 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed.</p> |
| 0   | CCS/CPE  | <p>0 Write of 0 has no effect.</p> <p>1 Write of 1 to this bit clears the port 0 port enable bit.</p>                                                                                                                                                                                                                                                                         | <p>Port 0 current connection status/clear port enable</p> <p>When read as 1, indicates that port 0 currently has a USB device attached. When 0, indicates that no USB device is attached to port 0.</p> <p>This bit is set to 1 after root hub reset if the HCRHDESCRIPTORB.DR[1] bit is set to indicate a non-removable device on port 0.</p>                                                                            |

### 29.2.4.23 HC Port 1 Status and Control Register (HCRHPORTSTATUS1)

The HC port 1 status register reports and controls the state of USB host port 1.

#### 29.2.4.24 Host UE Address Register (HOSTUEADDR)

The host UE address register reports the physical address of the last OCPI bus access that caused an unrecoverable error (UE). This register has no meaning until an unrecoverable error has occurred. It also has no meaning if the USB host controller issues an unrecoverable error because the offset checking fault occurred while processing an isochronous TD. This register is not defined by the OHCI specification.

**Figure 29-24. Host UE Address Register (HOSTUEADDR) [address = FCF78BE0h]**

LEGEND: R = Read only; -n = value at reset

**Table 29-26. Host UE Address Register (HOSTUEADDR) Field Descriptions**

| Bit  | Field   | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------|---------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | UE_ADDR | 0-FFFF FFFFh | Unrecoverable error address<br><br>This register captures the physical address of any bus transaction that is started by the USB host controller that encounters an unrecoverable error condition. This information, along with the information in HOSTUESTATUS, can help a developer determine why the USB host issued an access to a physical address that resulted in an unrecoverable error. |

#### 29.2.4.25 Host UE Status Register (HOSTUESTATUS)

The host UE status register reports the bus cycle-type for the last unrecoverable error that occurred. This register has no meaning until an unrecoverable error has occurred. It also has no meaning if the USB host controller issues an unrecoverable error because the offset checking fault occurred while processing an isochronous TD. This register is not defined by the OHCI specification.

**Figure 29-25. Host UE Status Register (HOSTUESTATUS) [address = FCF78BE4h]**

| 0    | UEACCESS | 0-1   | Access type when unrecoverable error occurred<br><br>When an unrecoverable error occurs because of time-out of a bus write, this bit is set. When an unrecoverable error occurs because of time-out of a bus read, this bit is cleared. This bit has no meaning before an unrecoverable error occurs.<br><br>This information, along with the information in HOSTUEADDR, can help a developer determine why the USB host issued a bus access that resulted in an unrecoverable error. |

### 29.2.4.26 Host Time-out Control Register (HOSTTIMEOUTCTRL)

The host time-out control register controls the USB host controller bus time-out mechanism. This register is not defined by the OHCI specification.

**Figure 29-26. Host Time-out Control Register (HOSTTIMEOUTCTRL) [address = FCF78BE8h]**

|     |          |        |

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

**Table 29-28. Host Time-out Control Register (HOSTTIMEOUTCTRL) Bit Field Descriptions**

| Bit  | Field    | Value | Description                                                                                                                                                                                                                                                                |
|------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-1 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                   |
| 0    | TO_DIS   | 0     | Bus time-out disable<br>When 0 (the default state), the USB host controller waits no more than 4096 VCLK3 clocks for completion of a bus access to system memory. If the bus cycle does not complete in that time, the USB host controller signals an unrecoverable error. |
|      |          | 1     | When 1, the USB host controller bus time-out counter is disabled and the host controller waits indefinitely for completion of a USB host controller access to system memory.                                                                                               |

### 29.2.4.27 Host Revision Register (HOSTREVISION)

The host revision register returns the revision number for the USB host controller. This register is not defined by the OHCI specification.

**Figure 29-27. Host Revision Register (HOSTREVISION) [address = FCF78BECh]**

|          |          |          |
|----------|----------|----------|

| 7-4  | MAJORREV | 0-Fh  | Major revision number<br>MAJORREV indicates the major revision number of the USB host controller. The original USB host controller version implements a major revision number of 0. |
| 3-0  | MINORREV | 0-Fh  | Minor revision number<br>MINORREV indicates the minor revision number of the USB host controller. The original USB host controller version implements a minor revision number of 0. |

### 29.2.5 USB Host Controller Reserved Registers and Reserved Bit Fields

To enhance code reusability with possible future versions of the USB host controller, reads and writes to reserved USB host controller register addresses are to be avoided. Unless otherwise specified, when writing registers that have reserved bits, read-modify-write operations must be used so that the reserved bits are written with their previous values.

### 29.2.6 USB Host Controller Registers, USB Reset, and USB Clocking

The Global Clock Module (GCM) provides VCLK3 to the USB host controller for the bus accesses. The GCM also provides the 48MHz clock (VCLKA3) and 12MHz clock (VCLKA3\_DIVR) to the USB host controller. If the application disables the VCLK3 domain or the VCLKA3 domain from the GCM, reads from and writes to the USB host controller registers do not occur correctly. To properly access the USB host controller registers, the USB host controller must be clocked and must be out of reset.

The USB host controller hardware reset is controlled by the system reset signal from the SYS module. The USB host controller is held in reset whenever the system reset signal is low or the HostControllerReset (HCR) field of the HcCommandStatus Register is 1. The USB host controller can transition out of reset whenever the clock is enabled and system reset is high and HcCommandStatus.HCR is 0.

The USB host controller completes its reset within about 72 cycles of the 48-MHz clock after the host controller clock transitions out of reset. After system software turns on the clock to the USB host controller and removes it from reset, it is necessary to wait until the USB host controller internal reset completes. To ensure that the USB host controller has completely reset, system software must wait until reads of both the HCREVISION register and the HCHCCA register return their correct reset default values.

### 29.2.7 OHCI Interrupts

The USB host controller provides an interrupt output to the Vectored Interrupt Manager (VIM). This is a level-sensitive interrupt signal.

#### 29.2.7.1 OHCI Scheduling Overrun Interrupt

The OHCI scheduling overrun interrupt is supported as described in the *OHCI Specification for USB*.

#### 29.2.7.2 OHCI HCDONEHEAD Writeback Interrupt

The OHCI HCDONEHEAD writeback interrupt is supported as described in the *OHCI Specification for USB*.

#### 29.2.7.3 OHCI Start Of Frame Interrupt

The OHCI start of frame interrupt is supported as described in the *OHCI Specification for USB*.

#### 29.2.7.4 OHCI Resume Detect Interrupt

The OHCI resume detect interrupt is supported as described in the *OHCI Specification for USB*.

#### 29.2.7.5 OHCI Unrecoverable Error Interrupt

The OHCI unrecoverable error interrupt is supported as described in the *OHCI Specification for USB*. This interrupt occurs if the USB host controller is unable to complete a bus read or write within 4096 VCLK3 clocks when the USB host bus time-out feature is enabled. When a bus time-out causes an unrecoverable error, HOSTUEADDR and HOSTUESTATUS are updated. When an isochronous TD is processed with an OFFSET/PSW field that is not set for *Not Accessed*, an unrecoverable error interrupt is generated, but HOSTUEADDR and HOSTUESTATUS are not updated.

#### 29.2.7.6 OHCI Frame Number Overflow

The OHCI frame number overflow interrupt is supported as described in the *OHCI Specification for USB*.

### 29.2.7.7 OHCI Root Hub Status Change

The OHCI root hub status change interrupt is supported as described in the *OHCI Specification for USB*.

### 29.2.7.8 OHCI Ownership Change Interrupt

The optional OHCI ownership change interrupt is not supported.

## 29.2.8 USB Host Controller Access to System Memory

The USB host controller has access to system memory to read and write the OHCI data structures and data buffers associated with USB traffic.

### 29.2.9 Physical Addressing

All system memory accesses initiated by the USB host controller use physical addresses.

## 29.2.10 USB Host Controller Bus Addressing and OHCI Data Structure Pointers

The USB host controller OHCI registers that point to the HCCA and the ED lists must be programmed with values that correspond to the physical addresses of the particular data structure. System software must use physical addresses when manipulating the OHCI control registers that point to the HCCA, and to the ED and TD lists. System software must also use physical addresses for the ED and TD pointers that are stored within ED and TD entries.

The USB host controller driver software must also be able to examine the list of completed transfer descriptors that the host controller creates as it retires transfer descriptors. This list is pointed to by the HCDONEHEAD register, which contains a physical address that points to the most recent transfer descriptor that has been retired.

### 29.2.11 NULL Pointers

The *OHCI Specification for USB* uses NULL pointers to indicate the end of a list. The USB host controller compares the ED and TD pointers against the value 0x00000000 to determine if the pointer is a null pointer. Address conversion routines must understand this usage.

## 29.2.12 USB Host Controller Power Management

Power management of the USB host controller is limited to disabling the clock to the USB host by clearing UHOST\_EN. When UHOST\_EN is 0, the USB host controller clocks are disabled and the USB host controller is held in reset. The USB signal multiplexing controlled by register in the I/O Multiplexing Module (IOMM).

When the host controller 48-MHz clock is disabled or UHOST\_EN is 0, all USB host controller OHCI registers and the HOSTUEADDR, HOSTUESTATUS, HOSTTIMEOUTCTRL, and HOSTREVISION registers are inaccessible.

## 29.3 USB Device Controller

The USB device controller supports the implementation of a full-speed device fully compliant with the USB 1.1 standard.

It provides an interface between the host processor and the USB wire and handles USB transactions with minimal CPU software intervention.

The USB device controller module supports one control endpoint (EP0), up to 15 IN endpoints, and up to 15 OUT endpoints. The exact endpoint configuration is software programmable. The specific items of a configuration are for each endpoint, the size in bytes, the direction (IN, OUT), the type (bulk/interrupt or ISO), and the associated number.

The USB device controller module also supports three DMA channels for IN endpoints and three DMA channels for OUT endpoints for either bulk/interrupt or ISO transactions.

### 29.3.1 USB Device Controller Registers

Table 29-30 lists the USB device controller registers. These registers are aligned at a 16-bit boundary, so that the memory address offsets for the registers are 0, 2h, 4h, 6h, and so on. The registers support 8-bit and 16-bit read/write accesses. A 32-bit read access will return the same contents on the upper 16 bits as on the lower 16 bits. Section 29.3.1.1 through Section 29.3.1.23 describe the register bits.

**Table 29-30. USB Device Controller Registers**

| Address                       | Register          | Description                             | Section                           |

### 29.3.1.1 Revision Register (REV)

This read-only register contains the revision number of the module. A write to this register is denied.  
Device reset and USB controller reset have no effect on this register.

**Figure 29-28. Revision Register (REV) [address = FCF78A00h]**

LEGEND: R = Read only; -n = value at reset

### 29.3.1.3 Data Register (DATA)

This register is the entry point to write into a selected TX endpoint or to read data from a selected RX endpoint, or to read data from setup FIFO. If selected endpoint direction is OUT, this register is read-only and a write into it is denied. If selected endpoint direction is IN, this register is write-only and a read to this register is denied.

**Table 29-33. Data Register (DATA) Field Descriptions**

| Bit  | Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | DATA  | <p>Transmit/receive FIFO data:</p> <p>EP_NUM.EP_DIR = 1: This register contains the data written by the USB device controller to be sent to the USB host during the next IN transaction. Data can be written successfully only if the EP_NUM.EP_SEL bit is asserted.</p> <p>EP_NUM.EP_DIR = 0: This register contains the data received by the USB core from USB host OUT or SETUP transactions. Data can be read successfully only if the EP_NUM.EP_SEL bit is asserted, or if EP_NUM.SETUP_SEL bit is asserted (for setup data).</p> |

### 29.3.1.4 Control Register (CTRL)

This set-only register controls the FIFO and status of the selected endpoint. A read access to this register always returns 0.

Endpoint 0 setup FIFO is always enabled and ready to accept setup data. No control register CTRL is implemented for this FIFO because the USB device controller cannot control it.

| 2    | SET_FIFO_EN | 0<br>1 | The set FIFO enable (non-ISO) bit only concerns non-ISO endpoints. If the selected endpoint direction is IN, the USB device controller uses this bit to enable the USB device to transmit data from the FIFO at the next valid IN token. If the selected endpoint direction is OUT, the USB device controller uses this bit to enable the USB device to receive data from the USB host at the next valid OUT transaction. If not, setting the device returns a NAK handshake. ISO endpoints FIFO are always enabled.<br><br>Note: The USB device controller must never enable endpoint 0 FIFO out of control transfers. For bulk and interrupt endpoints, FIFO must never be enabled when the halt feature is set or when RX FIFO is not empty. Furthermore, during EP interrupts handling, the USB device controller must have cleared the interrupt bit before setting CTRL.SET_FIFO_EN bit (to avoid masked ACK interrupts).<br><br>No action<br>FIFO enabled<br>Always read 0. |
| 1    | CLR_EP      | 0<br>1 | Clear endpoint: the USB device controller sets this bit to clear the selected endpoint FIFO pointers and flags. This bit resets the FIFO pointers, the FIFO empty status bit is set, and the FIFO enable bit and other FIFO flags are cleared upon completion of the FIFO reset. It also clears the previous transaction handshake status. For ISO endpoints or non-ISO double-buffered endpoints, both foreground and background FIFO are cleared.<br><br>No action<br>Clear endpoint<br>Always read 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 29-34. Control Register (CTRL) Field Descriptions (continued)**

| Bit | Field    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | RESET_EP |       | The endpoint reset (non-control) bit only concerns non-control endpoints. The USB device controller sets this bit to reset the selected endpoint. It forces an interrupt or a bulk endpoint data PID to DATA0, clears the halt condition, and clears the FIFO (both foreground and background if endpoint is double-buffered) and previous transactions handshake status. For an ISO endpoint, it only clears the FIFO (both foreground and background). |
|     |          | 0     | No action                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 29.3.1.5 Status Register (STAT\_FLG)

This read-only register provides a status of the FIFO and the results of the transactions handshakes for the selected endpoint. The 8 MSB are reserved for ISO endpoints, whereas the 8 LSB are reserved for non-ISO endpoints. This register cannot be read if EP\_NUM.EP\_SEL bit is not asserted for the endpoint. No status flag exists for the read-only set-up FIFO, which is always enabled.

**NOTE:** The updates for non-ISO transactions are done at the end of each non-transparent and valid transaction to a given endpoint, if no non-handled interrupt is pending on the endpoint.

The definition of a non-transparent, non-ISO IN transaction is one that responds with an ACK handshake or a STALL handshake, or optionally a NAK handshake if SYSCON1.NAK\_EN is asserted to 1. An ERR handshake or a NAK handshake when SYSCON1.NAK\_EN is 0 is considered transparent.

A write to this register has no effect.

**Table 29-35. Status Register (STAT\_FLG) Field Descriptions**

| Bit | Field        | Value | Description                                                                                                                                                                                                                                         |
|-----|--------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | NO_RX_PACKET |       | The isochronous no packet received (ISO OUT) bit only concerns ISO OUT endpoints. This bit notifies the USB device controller that the core has not received any isochronous packet on the endpoint. This bit is updated on a SOF (start of frame). |
|     |              | 0     | The endpoint received a packet on the previous frame.                                                                                                                                                                                               |
|     |              | 1     | The endpoint did not receive a packet on the previous frame.                                                                                                                                                                                        |
|     |              |       | Value after system reset or USB reset is high.                                                                                                                                                                                                      |

**Table 29-35. Status Register (STAT\_FLG) Field Descriptions (continued)**

| Bit   | Field          | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14    | MISS_IN        | 0<br>1 | <p>The isochronous missed IN token for the previous frame (ISO IN) bit only concerns ISO IN endpoints. This bit notifies the USB device controller that the core missed a valid ISO IN token during the previous frame and that TX data were flushed from the FIFO instead of being transmitted to the USB host.</p> <p>This bit is updated on a SOF (start of frame).</p> <p>The endpoint received an IN token the previous frame.</p> <p>The endpoint did not receive an IN token the previous frame and TX data were flushed.</p> <p>Value after system reset or USB reset is low.</p>             |
| 13    | DATA_FLUSH     | 0<br>1 | <p>The isochronous receive data flush (ISO OUT) bit only concerns ISO OUT endpoints. When set, this bit indicates that data were flushed from the isochronous FIFO that was moved from the foreground to the background. This happens when the USB device controller does not read all of the data from the foreground FIFO in a frame.</p> <p>This bit is updated in every frame.</p> <p>Not significant.</p> <p>Data was flushed.</p> <p>Value after system reset or USB reset is low.</p>                                                                                                          |
| 12    | ISO_ERR        | 0<br>1 | <p>The isochronous receive data error (ISO OUT) bit only concerns ISO OUT endpoints. When set, this bit indicates that the ISO data packet was received incorrectly. This happens when the core detects an error in the data packet (CRC, bit stuffing, PID check) or when there is an overrun condition in the FIFO. When this bit is set, the FIFO contents are automatically flushed by the core and the FIFO status is empty.</p> <p>This bit is updated in every frame.</p> <p>Not significant.</p> <p>ISO packet received with errors.</p> <p>Value after system reset or USB reset is low.</p> |
| 11-10 | Reserved       | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 9     | ISO_FIFO_EMPTY | 0<br>1 | <p>The ISO FIFO empty bit only concerns ISO endpoints. This bit is set when the FIFO for the selected ISO endpoint is empty, either via an appropriate CTRL.CLR_EP bit or CTRL.RESET_EP bit or after successful reads from the selected FIFO.</p> <p>ISO FIFO is not empty.</p> <p>ISO FIFO is empty.</p> <p>Value after system reset or USB reset is high (FIFO empty).</p>                                                                                                                                                                                                                          |
| 8     | ISO_FIFO_FULL  | 0<br>1 | <p>The ISO FIFO full bit only concerns ISO endpoints. This bit is set when the FIFO for the selected ISO endpoint is full. This condition is cleared by setting the CTRL.CLR_EP bit or CTRL.RESET_EP bit, or after one successful read (by the USB device controller or the USB host).</p> <p>ISO FIFO is not full.</p> <p>ISO FIFO is full.</p> <p>Value after system reset or USB reset is low (FIFO empty).</p>                                                                                                                                                                                    |
| 7     | Reserved       | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 6     | EP_HALTED      | 0<br>1 | <p>The endpoint halted flag (non-ISO) bit only concerns non-ISO endpoints. This bit when asserted 1 indicates that the selected endpoint is halted. The endpoint can be put into the halt state only by the USB device controller writing the endpoint halt control bit (in response to a SET_FEATURE request, for instance).</p> <p>The selected endpoint is not halted.</p> <p>The selected endpoint is halted.</p> <p>Value after system reset or USB reset is low.</p>                                                                                                                            |

### 29.3.1.6 Receive FIFO Status Register (RXFSTAT)

This read-only register indicates how many bytes are in the receive FIFO for the selected endpoint. A write to this register has no effect. The USB device controller cannot read this register if the EP\_NUM.EP\_SEL bit is not set for the endpoint. No receive FIFO status exists for the setup FIFO, because 8 bytes are always expected.

**Figure 29-33. Receive FIFO Status Register (RXFSTAT) [address = FCF78A0Ah]**

LEGEND: R = Read only; -n = value at reset

### Table 29-36. Receive FIFO Status Register (RXFSTAT) Field Descriptions

| Bit   | Field     | Value  | Description                                                                                                                                                        |
|-------|-----------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-10 | Reserved  | 0      | Reserved                                                                                                                                                           |
| 9-0   | RXF_COUNT | 0-3FFh | The receive FIFO byte count 10-bit field indicates the number of bytes currently in the receive FIFO. Values after system reset or USB reset is low (all 10 bits). |

### 29.3.1.7 System Configuration Register 1 (SYSCON1)

This read/write register provides control functions for power management and miscellaneous control for the core.

Values depend on whether the reset action comes from the USB device controller (CPU) or the USB host.

**Figure 29-34. System Configuration Register 1 (SYSCON1) [address = FCF78A0Ch]**

| 15-9 | Reserved    | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 8    | CFG_LOCK    | 0<br>1 | Device configuration locked bit: after the USB device controller has entered the device configuration (registers 0x20 to 0x3F), it must set the CFG_LOCK bit so that the device can be used. When the device configuration is not locked, the device is not ready to be used.<br><br>Device configuration is not locked. Device is not ready<br>Device configuration is locked.<br><br>The value after the USB device controller hardware reset is low; after USB reset, it is unchanged (keep previous configuration).                                                                                                                                                                    |
| 7    | DATA_ENDIAN | 0<br>1 | The data endian bit can be set by the USB device controller to select little- or big-endian format on data access (read or write). See <a href="#">Table 29-38</a> .<br><br>Little endian<br>Big endian<br><br>The value after USB device controller hardware reset is low; after USB reset, it is unchanged (keep previous configuration).                                                                                                                                                                                                                                                                                                                                                |
| 6    | DMA_ENDIAN  | 0<br>1 | The DMA data endian bit can be set by the USB device controller to select little- or big-endian format on data access (read or write). See <a href="#">Table 29-38</a> .<br><br>Little endian<br>Big endian<br><br>The value after USB device controller hardware reset is low; after USB reset, it is unchanged (keep previous configuration).                                                                                                                                                                                                                                                                                                                                            |
| 5    | Reserved    | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4    | NAK_EN      | 0<br>1 | The NAK enable bit can be set by the USB device controller to be signaled for NAK transaction handshake response. When this bit is set, STAT_FLG.NAK is set on a NAK handshake if no non-handled interrupt is pending on the endpoint, and the endpoint interrupt is asserted. In the normal mode, when cleared, NAK handshake response to the USB host is made transparent to the USB device controller and no interrupt is asserted.<br><br>NAK is disabled.<br>NAK is enabled.<br><br>The value after system reset or USB reset is low.<br><br><b>Note: If the USB device controller sets this bit, it must wait for a NAK interrupt before selecting TX endpoint to write TX data.</b> |
| 3    | AUTODEC_DIS | 0<br>1 | The autodecode process disabled can be set to force software to handle all EP0 transactions (except the SET_ADDRESS transaction).<br><br>Autodecode process is activated (see <a href="#">Table 29-55</a> ).<br>Autodecode process is deactivated. The value after USB device controller hardware reset is low; after USB reset, it is unchanged.                                                                                                                                                                                                                                                                                                                                          |

**Table 29-37. System Configuration Register 1 (SYSCON1) Field Descriptions (continued)**

| Bit | Field     | Value                                                                                                                                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                       |
|-----|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2   | SELF_PWR  | 0 Bus powered<br>1 Self-powered<br>The value after USB device controller hardware reset is low; after USB reset, it is unchanged.                                                                                                                                    | The self-powered bit indicates to the USB host whether the device is bus-powered or self-powered. This information is needed for an autodecoded request. The USB device controller must update this bit after a SET_CONFIGURATION according to the self-powered bit D6 given in the configuration descriptor (see <i>USB 1.1 Specification</i> ). |
| 1   | SOFF_DIS  | 0 Power shutoff circuitry is enabled.<br>1 Power shutoff circuitry is disabled.<br>The value after USB device controller hardware reset is low; after USB reset, it is unchanged.                                                                                    | When the shutoff disable bit is set, it disables the power shutoff circuitry.                                                                                                                                                                                                                                                                     |
| 0   | PULLUP_EN | 0 Pull-up is disabled. USB host cannot detect the device. In this mode, the 48-MHz USB clock is forced off.<br>1 Pull-up is enabled.<br>The value after USB device controller hardware reset is low; after USB reset, it is high; and after detach, it is unchanged. | The external pullup enable bit allows the device to disconnect itself from the USB bus, forcing the host to reset and reconfigure the device. This bit can be used to prevent USB traffic when the device is not ready.                                                                                                                           |

LEGEND: R = Read only; W = Write only; -n = value at reset

**Table 29-39. System Configuration Register 2 (SYSCON2) Field Descriptions**

| Bit  | Field     | Value                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|-----------|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-7 | Reserved  | 0                                                                          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 6    | RMT_WKP   | 0 No action.<br>1 Initiates the remote wake-up sequence.<br>Always read 0. | The set-only remote wake-up bit, when written with a 1, initiates the remote wake-up sequence even if DEVSTAT.R_WK_OK bit was not previously set to 1 by the USB host. Reading this bit always returns 0. Writing 0 into this bit has no effect. To generate a resume, the software must check the remote wake-up enable value before initiating any wake-up sequence.                                                                                                                                                                                                                                                                                    |
| 5    | STALL_CMD | 0 No action.<br>1 Stall current USB command.<br>Always read 0.             | The set-only stall command bit only concerns non-autodecoded requests on control endpoint (EP0). This is asserted in response to a USB command where either the command itself or its data is invalid. Asserting this bit forces the non-autodecoded command to complete with a STALL handshake. It has no effect for autodecoded requests.                                                                                                                                                                                                                                                                                                               |
| 4    | Reserved  | 0                                                                          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3    | DEV_CFG   | 0 No action.<br>1 Allows DEVSTAT.CFG to be set.<br>Always read 0.          | If the USB device controller receives a SET_CONFIGURATION with a valid configuration value, and the device is in addressed state, it must write a 1 to the device configured (DEV_CFG) bit to inform the command decode that the device moves to configured state. The core sets the DEVSTAT.CFG bit to 1. If the device is already configured when the SET_CONFIGURATION request is received, the USB device controller does not have to set this bit. If the new configuration value is 0, USB device controller must set the SYSCON2.CLR_CFG bit to move to addressed state. Reading this bit always returns 0. Writing 0 into this bit has no effect. |
| 2    | CLR_CFG   | 0 No action.<br>1 Allows DEVSTAT.CFG to be cleared.<br>Always read 0.      | If the USB device controller receives a SET_CONFIGURATION with a configuration value of 0, and if the device is configured, it must write a 1 to the clear configured (CLR_CFG) bit to inform the command decode that the device becomes deconfigured (moves to addressed state). The core clears the DEVSTAT.CFG bit. Reading this bit always returns 0. Writing 0 into this bit has no effect.                                                                                                                                                                                                                                                          |
| 1-0  | Reserved  | 0                                                                          | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 29.3.1.9 Device Status Register (DEVSTAT)

This read-only register provides a status reflecting the visible device states as defined in *USB1.1 Specification*. A write to this register has no effect.

**NOTE:** This register is double buffered. If IRQ\_EN.DS\_CHG\_IE is set (interrupt enabled), the background register is moved into foreground position only after clearing any pending DS\_CHG interrupt. Therefore, if there is a state change and a pending DS\_CHG interrupt has not been serviced yet, then the recent state change is not visible, because the background register was only updated and not moved into the foreground position.

The values depend on whether the reset action comes from the USB device controller (CPU) or USB host. They also depend on whether the device is attached or not when the USB device controller hardware reset event occurs.

| 7     | A_ALT_HNP_SUPPORT | 0<br>1 | The B-device is connected to an A-device port that is not capable of HNP, but the A-device has an alternate port that is capable of HNP. This A_ALT_HNP_SUPPORT bit is used for On-The-Go feature selection purposes. See the <i>On-The-Go Supplement</i> to the <i>USB 2.0 Specification</i> .<br>Not significant.<br>B-device connection to not HNP capable A-device.<br>Value after system reset or USB reset is low. |
| 6     | R_WK_OK           | 0<br>1 | The remote wake-up granted bit is automatically set and cleared when the core receives a valid set/clear device feature request from the USB host. It returns a 1 when the USB host grants the function the ability to assert remote wake-up.<br>Not significant.<br>Remote wake-up granted.<br>Value after system reset or USB reset is low.                                                                            |

**Table 29-40. Device Status Register (DEVSTAT) Field Descriptions (continued)**

| Bit | Field     | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|-----------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | USB_RESET | 0<br>1 | <p>USB reset signaling is active. The USB_RESET bit returns 1 when the USB host resets the USB bus. A valid USB reset resets the endpoint FIFOs, the other control register bits, except for SYSCON1.CFG_LOCK and the associated configuration registers (0x20 to 0x3F), IRQ_EN.DS_CHG_IE and IRQ_SRC.DS_CHG, and forces the device to the default state for DEVSTAT (this register). This bit is cleared at the end of reset. This bit, as well as other DEVSTAT bits, is double-buffered. If a pending interrupt has not been handled when a USB reset occurs and is handled only when USB reset is finished, the USB device controller does not see the USB_RESET bit going high and then low.</p> <p>Device is not being reset by USB host.</p> <p>Device is being reset by USB host.</p> <p>The value after the USB device controller hardware reset is low, and during USB reset is high (low after USB reset).</p> |
| 4   | SUS       | 0<br>1 | <p>Suspended state bit: the device in suspended state is, at a minimum, attached to the USB, powered, has been reset by the USB host, and has not seen bus activity for 5 ms. It can also have a unique address and be configured for use. Because the device is suspended, however, the host cannot use the device function. This bit returns 1 when the USB device is in a suspended state.</p> <p>Not suspended</p> <p>Suspended</p> <p>Value after system reset or USB reset is low.</p>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 3   | CFG       | 0<br>1 | <p>Configured state bit: the device is attached to the USB, powered, has been reset, has a unique address, and is configured. The host can use the function provided by the device. This bit returns 1 when the USB device has been configured after a set SYSCON2.DEV_CFG = 1. This bit remains set to 1 until the device becomes deconfigured. This bit is cleared when the core receives a valid SET_CONFIGURATION request and the USB device controller sets the SYSCON2.CLR_CFG bit. During the time this bit is not set to 1, transactions that are not for control EP0 are ignored. A GET_ENDPOINT_STATUS to a non-control endpoint is stalled.</p> <p>Not configured</p> <p>Configured</p> <p>Value after system reset or USB reset is low.</p>                                                                                                                                                                   |
| 2   | ADD       | 0<br>1 | <p>Addressed state bit: the device is attached to the USB, powered, has been reset, and a unique device address has been assigned. This bit (ADD) returns 1 after an ET_ADDRESS standard request. This bit remains set to 1 until the device becomes de-addressed.</p> <p>Not addressed</p> <p>Addressed</p> <p>Value after system reset or USB reset is low.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 29.3.1.10 Start of Frame Register (SOF)

This read-only register provides a frame timer status for use in ISO communications. A write to this register is denied.

**Figure 29-37. Start of Frame Register (SOF) [address = FCF78A12h]**

LEGEND: R = Read only; -n = value at reset

**Table 29-41. Start of Frame Register (SOF) Field Descriptions**

| Bit   | Field    | Value                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 12    | FT_LOCK  | <div>0</div> <div>1</div> | <p>Frame timer locked bit: the USB host sends out a start of frame (SOF) packet every millisecond. When the device does not receive a SOF packet because of a bus error, a local start-of-frame that is used for ISO FIFO switch is generated. Once the core receives two valid SOF, separated by TF (time frame), it sets SOF.FT_LOCK to 1, only if TF is in frame interval IF allowed by the USB 1.1 specification (IF = [11964:12036] USB bit time). If TF is out of this interval, SOF.FT_LOCK value remains 0, and a local SOF is generated by the core. When SOF.FT_LOCK is set and the frame timer is locked to the timing TF, a local SOF is generated, if no valid SOF has been received in an interval of TF since the last valid SOF. The SOF.FT_LOCK bit is cleared if a valid SOF is received out of the interval IF. If the core receives a valid SOF in this interval, the frame timer locks to the new frame time. If the core does not receive a valid SOF, the frame timer remains locked to TF. When SOF.FT_LOCK is cleared, a local SOF is generated after the 12036 USB bit time, if no valid SOF has been received, and SOF.FT_LOCK remains 0.</p> <p>Frame timer is not locked.</p> <p>Frame timer is locked.</p> <p>The value after system reset or USB reset is low. Note: Each time the core receives a valid SOF out of the allowed interval IF, a local SOF is generated and the ISO FIFO switches.</p> |
| 11    | TS_OK    | <div>0</div> <div>1</div> | <p>The timestamp OK bit indicates that the timestamp in SOF.TS is valid for the current frame. It returns a 1 if a valid SOF packet was received from the USB host and a 0 otherwise.</p> <p>Timestamp is invalid.</p> <p>Timestamp is valid.</p> <p>Value after system reset or USB reset is low.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 10-0  | TS       | 0-7FFh                    | The timestamp number field returns the timestamp from the last USB host-valid SOF packet. The frame number is valid if SOF.TS_OK is 1. In case of an SOF miss, this value is not updated and TS_OK is cleared. The value after system reset or USB reset is low (all 11 bits).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 29.3.1.11 Interrupt Enable Register (IRQ\_EN)

This read/write register enables all non-DMA interrupts (control, state changed, ISO, and non-ISO).

The values depend on whether the reset action comes from the USB device controller (CPU) or the USB host.

When the USB device controller sets a bit position to 1, an interrupt is signaled to the USB device controller if the corresponding IRQ\_SRC bit is asserted to 1 by the core for any IRQ\_SRC bit controlled by this bit. If reset to 0, the interrupt is masked and not signaled to the USB device controller.

- 0: Interrupt is disabled.
- 1: Interrupt is enabled.

The value after system reset or USB reset is low for all bits except IRQ\_EN.DS\_CHG\_IE bit, which remains unchanged after a reset from the USB host.

**Figure 29-38. Interrupt Enable Register (IRQ\_EN) [address = FCF78A14h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

**Table 29-42. Interrupt Enable Register (IRQ\_EN) Field Descriptions**

| Bit  | Field     | Value | Description                                    |
|------|-----------|-------|------------------------------------------------|
| 15-8 | Reserved  | 0     | Reserved                                       |
| 7    | SOF_IE    | 0-1   | Start of frame interrupt enable                |
| 6    | Reserved  | 0     | Reserved                                       |
| 5    | EPn_RX_IE | 0-1   | Receive endpoint n interrupt enable (non-ISO)  |
| 4    | EPn_TX_IE | 0-1   | Transmit endpoint n interrupt enable (non-ISO) |
| 3    | DS_CHG_IE | 0-1   | Device state changed interrupt enable          |
| 2-1  | Reserved  | 0     | Reserved                                       |
| 0    | EP0_IE    | 0-1   | EP0 transactions interrupt enable              |

### 29.3.1.12 DMA Interrupt Enable Register (DMA\_IRQ\_EN)

This read/write register enables all DMA interrupts.

When the USB device controller sets a bit position to 1, an interrupt is signaled to the USB device controller if the corresponding bit in the IRQ\_SRC register is asserted to 1 by the core. If reset to 0, the interrupt is masked and not signaled to the USB device controller.

- 0: Interrupt is disabled.
- 1: Interrupt is enabled.

The value after system reset or USB reset is low for all bits.

### 29.3.1.13 Interrupt Source Register (IRQ\_SRC)

This read/clear only register identifies and clears the source of the interrupt signaled by a set flag.

The value depends on whether the reset action comes from the USB device controller (CPU) or the USB host.

The USB device controller can clear a set bit location only by writing a 1 into the bit location (except for the setup bit, which is automatically cleared by the core). A write of 0 has no effect.

When the core sets a bit location to 1, an interrupt is signaled to the USB device controller if the interrupt was enabled.

- 0: No interrupt
- 1: Interrupt signaled

The value after the system reset or USB reset is low except for the IRQ\_SRC.DS\_CHG bit, which is high after a USB reset.

| 15-11 | Reserved | 0      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 10    | TXn_DONE | 0<br>1 | The transmit DMA channel n done interrupt flag (non-ISO) bit is only for non-ISO DMA transfer. This bit is never set for ISO DMA transfer. The core automatically sets this bit when a transmit DMA channel has completed the programmed transfer by servicing the last IN transaction from the USB host. This is when TXDMA.TXn_TSC (transfer size counter) equals 0, and the last IN transaction completes with an ACK. When this bit is asserted, the USB device controller must read the DMAN_STAT register to identify the endpoint number for which the transfer completed. The endpoint interrupt IRQ_SRC.EPn_TX is never set for the assigned endpoint to TX DMA channel n.<br><br>0 No action.<br>1 Non-ISO transmit DMA transfer for a channel has ended.<br><br>The value after system reset or USB reset is low.                                                                                                                                                 |
| 9     | RXn_CNT  | 0<br>1 | The receive DMA channel n transactions count interrupt flag (non-ISO) bit is only for non-ISO DMA transfer. This bit is never set for ISO DMA transfer and never set if the interrupt enable bit associated with it is not set. It means that no poll operation is possible on the DMA. The core automatically sets this bit during an active Receive DMA transfer each time RXDMA.RXn_TC equals 0 after an OUT transaction with ACK status. This bit is set after the RX DMA data have been read (end of DMA request). When this bit is asserted, the USB device controller must read DMAN_STAT register to identify the endpoint number for which the transfer completed. An RXn_CNT IT is asserted also if RXDMA.RXn_STOP is set; in this case, both IRQ_SRC.RXn_EOT and IRQ_SRC.RXn_CNT are asserted.<br><br>0 No action.<br>1 Non-ISO receive DMA transfer for a channel has reached transactions count level.<br><br>The value after system reset or USB reset is low. |

**Table 29-44. Interrupt Source Register (IRQ\_SRC) Field Descriptions (continued)**

| Bit | Field    | Value                                                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------|------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8   | RXn_EOT  | <p>0 No action.</p> <p>1 Non-ISO receive DMA transfer for a channel has ended.</p> <p>The value after system reset or USB reset is low.</p>    | <p>The receive DMA channel n end of transfer interrupt flag (non-ISO) bit is for non-ISO DMA transfer only. This bit is never set for ISO DMA transfer and never set if the interrupt enable bit associated with it is not set. It means that no poll operation is possible on the DMA. The core automatically sets this bit when a receive DMA channel detects an end-of-transfer (EOT) packet during the last OUT transaction from the USB host. This bit is set after the RX DMA data have been read (end of DMA request). When this happens, the DMA assigned endpoint FIFO is kept disabled (STAT_FLG.FIFO_EN = 0) to avoid receiving a new packet data from the USB host. The USB device controller can grant DMA transfer again to the same endpoint by enabling the FIFO again (STAT_FLG.FIFO_EN = 1). An end of transfer is detected when the core receives a data packet that is less than the configured endpoint FIFO size (or is empty), or when RXDMA<sub>n</sub>.RXn_TC equals 0 after an OUT transaction with ACK status and the RXDMA<sub>n</sub>.RXn_STOP bit is set. When this bit is asserted, the USB device controller must read DMAN_STAT.DMAN_RX_IT_SRC to identify the endpoint number for which the transfer completed, and DMAN_STAT.DMAN_RX_SB must be informed of an odd number of bytes received during the last transaction (useful for 16-bit read access from the DATA_DMA register). The endpoint interrupt IRQ_SRC.EPn_RX is never set to RX DMA channel for the assigned endpoint.</p> |
| 7   | SOF      | <p>0 No action</p> <p>1 Start-of-frame packet received (or internal SOF)</p> <p>The value after system reset or USB reset is low.</p>          | <p>Start of frame interrupt flag bit: every millisecond, the USB host outputs a start-of-frame packet to the functions. The SOF bit reflects when a new SOF is received. Writing a 1 in the SOF bit location clears the flag. Writing a 0 has no effect. In accordance with the USB1.1 specification, if SOF is received corrupted or is not received, the core still sets this flag at the same rate (if bit SOF.FT_LOCK = 1) or after 12043 USB bit time (if bit SOF.FT_LOCK = 0).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 29.3.1.14 Non-ISO Endpoint Interrupt Status Register (EPN\_STAT)

This read-only register identifies the non-ISO endpoint causing an EPn interrupt. A write into it is denied.

**NOTE:** If a nontransparent transaction occurs before a previous one on another endpoint in the same direction that has been handled, the second interrupt is asserted only after the USB device controller clears the first one and EPN\_STAT is updated with the corresponding interrupt assertion.

**Figure 29-41. Non-ISO Endpoint Interrupt Status Register (EPN\_STAT) [address = FCF78A1Ah]**

### 29.3.1.16 DMA Receive Channels Configuration Register (RXDMA\_CFG)

This read/write register enables the three possible DMA receive channels and selects the endpoint number that is assigned to each of these DMA channels. An endpoint used by an RX DMA channel must have been configured (through register EPn\_RX). The RXDMA\_CFG register can be filled when SYSCON1.CFG\_LOCK is set.

Only one channel is serviced at a time, so it is better to configure ISO endpoints on the first channel (\_EP). If the ISO endpoint is configured on channel 2, it can never be serviced with low software and a fast USB host.

The USB device controller transmit endpoint DMA channels 0, 1, and 2 are associated with device controller inputs.

**NOTE:** System software must not program RXDMAx\_EP to endpoint numbers that are not configured as DMA endpoints.

| Bit  | Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | DATA_DMA | <p>DMA FIFO data. When an RX DMA request is active for a channel (only one active at a given time), this register contains the data that the core received from the USB host OUT transaction using this channel. Data can be accessed by the main DMA controller engine (read access) in response to the DMA request for the channel. When a TX DMA request is active for a channel (only one active at a given time), this register contains the data written by the main DMA controller engine (write access) in response to a DMA request for the transmit channel to be sent to the USB host during the next IN transaction.</p> <p>Note: It is possible for both an RX DMA request and a TX DMA request to be active at the same time. In this case, the main DMA controller engine can access both transmit endpoint and receive endpoint FIFO. A read access to DATA_DMA register affects the endpoint that caused the RX DMA request to be active, and a write access affects the endpoint that caused the TX DMA request to be active.</p> <p>Note: The USB device controller must not access this register directly; however, there is no hardware mechanism to prevent such access. No access into this register must be made out of DMA request handling.</p> |

### 29.3.1.19 Transmit DMA Control Register n (TXDMA<sub>n</sub>)

This read/write register controls the operation of the transmit DMA channel  $n$  ( $n = 0, 1, 2$ ).

|-------|-----------|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | TXn_EOT   | 0 DMA transfer size is in buffers.<br>1 DMA transfer size is in bytes.<br>Value after system reset or USB reset is low. | Transmit DMA channel $n$ end of transfer: the TXn_EOT bit can be either 0 or 1 for BULK DMA transfer. When the USB device controller sets it to 1, this bit signals the core that the transfer size set in TXDMA <sub>n</sub> .TXn_TSC is in bytes. A TX one interrupt (IRQ_SRC.TXn_DONE) is asserted with the last IN transaction. If the number of bytes set in TXDMA <sub>n</sub> .TXn_TSC is a multiple of the endpoint buffer size, the TX done interrupt is asserted only after an IN transaction with an empty data packet. When cleared, the transfer size set in TXn_TSC is in full buffer size for the endpoint selected (BULK only). A TX done interrupt is asserted when the last buffer is sent with the last IN transaction. This mode is to be used for a partial bulk transfer of a large file exceeding 1023 bytes.                                                                                                                                                                                                                                                                                                                                         |
| 14    | TXn_START | 0 No action.<br>1 DMA transfer start.<br>Always reads 0.                                                                | Transmit DMA channel $n$ start. The USB device controller sets this bit to tell the device that the main DMA system is ready to transmit the number of bytes or buffers. Once set, the DMA transfer cannot be interrupted, unless the USB device controller clears the endpoint in the TXDMA_CFG register. A write 0 into this bit has no effect and a read to this bit always returns 0. The IRQ_SRC.TXn_DONE interrupt bit is asserted when the DMA transfer ends.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 13-10 | Reserved  | 0                                                                                                                       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 9-0   | TXn_TSC   | 0-3FFh                                                                                                                  | Transmit DMA channel $n$ transfer size counter. The binary encoded value from 0 to 1023, which the USB device controller writes into this register, corresponds to the number of bytes or number of buffer transfers (function of TXDMA <sub>n</sub> .TXn_EOT) to be transmitted by the transmit DMA channel $n$ . When read, the register reflects the number of bytes/buffers the USB device has still to transmit. Read mode is only provided for software debug purposes.<br><br>Note: For ISO transfer, the user must verify that the set value does not exceed the ISO FIFO size for the endpoint. There is no hardware mechanism to prevent this situation. If this situation occurs, results are unpredictable.<br><br>Note: For bulk transfer, when TXDMA <sub>n</sub> .TXn_EOT = 0, a set value of TXDMA <sub>n</sub> .TXn_TSC = 0 means 1024 buffers and not 0. The counter then operates in the following way: 000, 3FF, 3FE, 0001, 000, stop. When TXDMA <sub>n</sub> .TXn_EOT = 1, a set value of TXDMA <sub>n</sub> .TXn_TSC = 0 a NULL packet is sent in response to the next IN token.<br><br>Values after system reset or USB reset are low (all 10 bits). |

### 29.3.1.20 Receive DMA Control Register n (RXDMAn)

This read/write register monitors incoming OUT transactions during DMA transfer on channel n (n=0,1,2).

| 15   | RXn_STOP | 0-1   | Receive DMA channel n transfer stop. When this bit is set, an RXn_EOT interrupt is asserted to the USB device controller after n OUT transactions where n is the encoded binary value + 1 programmed into RXDMAn.RXn_TC field. This register is used when no smaller than buffer size packet is received at an end-of-transfer (EOT), and the USB device controller expects a given amount of data for the transfer.<br><br>Note: At end of transfer, the DMA channel is disabled and all OUT transactions received to the assigned endpoint are sent NAK by the core. The USB device controller must set CTRL.SET_FIFO_EN for the endpoint to reenale the channel.<br><br>Values after system reset or USB reset are low.                                                                                          |
| 14-8 | Reserved | 0     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 7-0  | RXn_TC   | 0-FFh | Receive DMA channel n transactions count. The USB device controller can ask for an interrupt each n OUT transactions where n is the encoded binary value + 1 programmed into RXDMAn.RXn_TC field. This register must be programmed to the desired transaction watermark limit prior to enabling the DMA transfer for the receive DMA channel n.<br><br>Note: A reached watermark does not disable an active DMA transfer if RXDMAn.RXn_STOP was not set. If RXDMAn.RXn_STOP was set for the transfer both RXn_CNT and RXn_EOT interrupts are asserted. A read to that register returns the number of transactions remaining before the IRQ_SRC.RXn_CNT interrupt flag is asserted. This read mode is only provided for software debug purposes.<br><br>Values after system reset or USB reset are low (all 8 bits). |

### 29.3.1.21 Endpoint 0 Configuration Register (EP0)

This read/write register gives the device configuration for control endpoint 0.

Values depend on whether the reset action comes from USB device controller (CPU) or the USB host.

**Figure 29-48. Endpoint 0 Configuration Register (EP0) [address = FCF78A40h]**

LEGEND: R/W = Read/Write; R = Read only; -n = value at reset

**Table 29-52. Endpoint 0 Configuration Register (EP0) Field Descriptions**

| Bit   | Field    | Value                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 29.3.1.22 Receive Endpoint n Configuration Register (EPn\_RX)

This read/write register gives the device configuration for non-control receive endpoint n (1:15). The endpoints size fields must match values sent by the USB device controller to the USB host in response to the GET\_CONFIGURATION\_DESCRIPTOR during configuration phase.

The USB device controller must fill this field before setting SYSCON1.CFG\_LOCK and must not change the values once SYSCON1.CFG\_LOCK is set.

Values depend on whether the reset action comes from USB device controller (CPU) or USB host.

### 29.3.1.23 Transmit Endpoint n Configuration Register (EPn\_TX)

This read/write register gives the device configuration for non-control transmit endpoint n (1:15). The endpoints size fields must match the values sent by the USB device controller to the USB host in response to the GET\_CONFIGURATION\_DESCRIPTOR during configuration phase.

**NOTE:** The USB device controller must fill this field before setting SYSCON1.CFG\_LOCK and must not change the values once SYSCON1.CFG\_LOCK is set.

### 29.3.2 USB Device Transactions

There is an interrupt to the CPU at the end of an USB transaction if the CPU has actions to perform. Isochronous transactions are an exception because isochronous interrupt information is available at start of frame interrupts. The CPU ISR code determines which endpoint and direction caused the interrupt and acts appropriately. The following subsections describe in detail the activities surrounding USB transactions that are not part of a DMA transfer. Cases where a transaction occurs before the previous one has been handled by the CPU are not taken into account in this part. The information is organized so that each section deals with one type and direction of transaction, such as:

- Non-isochronous, non-setup OUT transactions
- Non-isochronous IN transactions
- Isochronous OUT transactions
- Isochronous IN transactions

This allows each section to focus only on a specific style of transaction without adding in the confusion of special cases related to other styles.

#### 29.3.3 Non-Isochronous, Non-Setup OUT (USB HOST→CPU) Transactions

Non-isochronous, non-setup OUT transactions refer to USB transactions where data is moved from the USB host to the CPU, the USB handshaking protocols are in effect, and data transmission is ensured. These types of transactions apply to all OUT transactions on bulk and interrupt endpoint types, and to non-setup transactions on control endpoints.

Figure 29-51 shows the various USB protocol conditions that can occur during non-isochronous, non-setup OUT transactions. The diagram shows the three phases that can occur in an OUT transaction, the direction of information flow for each phase, when endpoint interrupts are generated, and the resulting STAT\_FLG bits for the endpoint. The top three cases show the normal USB handshaking modes: acknowledge (good data received), NAK (device not ready to receive data), and STALL (device in a condition where the endpoint cannot handle OUT transactions). The last case is an abnormal instance where the token packet or the data packet was received with errors. The RX FIFO only contains valid receive data under the first (acknowledge) case.

**Figure 29-51. Non-Isochronous, Non-Control OUT Transaction Phases and Interrupts**

Successful data transfer to USB Host. (Endpoint STAT\_FLG.FIFO\_EN bit was set when token was received.)

After interrupt, EP's TX FIFO is empty.

STAT\_FLG bits after interrupt

| EP_Halted | STALL | NAK | ACK |
|-----------|-------|-----|-----|
| 0         | 0     | 0   | 1   |

No data transmitted by the LH. (Endpoint STAT\_FLG.FIFO\_EN bit was clear when token was received.)

EP TX FIFO is unchanged by this USB transaction.

STAT\_FLG bits after interrupt (SYSCON1.Nak\_En=1)

| EP_Halted | STALL | NAK | ACK |
|-----------|-------|-----|-----|
| 0         | 0     | 1   | 0   |

EP stalled. No data transmitted by the LH. (Endpoint STAT\_FLG.EP\_HALTED bit was set when token was received or an EPO control request error has occurred.)

EP TX FIFO is cleared by this USB transaction.

STAT\_FLG bits after interrupt

|    | EP_Halted | STALL | NAK | ACK |
|----|-----------|-------|-----|-----|
| or | 1         | 1     | 0   | 0   |
|    | 0         | 1     | 0   | 0   |

EP TX Data Error during transmission.

EP TX FIFO is unchanged by this USB transaction. No interrupt occurs. STAT\_FLG is unchanged.

 Indicates a packet received by the device

 Indicates a packet sent by the device

### 29.3.3.1 Non-Isochronous, Non-Control OUT Endpoint Handshaking Conditions

An endpoint CTRL.SET\_FIFO\_EN bit provides the main control for the endpoint ability to allow successful OUT transaction data reception for the endpoint. If at the beginning of an OUT transaction to an endpoint, the endpoint STAT\_FLG.FIFO\_EN bit is 1, the USB module is allowed to accept the OUT transaction data to the RX FIFO, and, when the transaction completes, the USB module can return ACK to the PC to indicate that the data was received correctly (this is the top case shown in [Figure 29-51](#)). If, however, the endpoint STAT\_FLG.FIFO\_EN bit was 0 at the beginning of an OUT transaction to the endpoint, the USB module returns NAK during the handshake phase to indicate that the endpoint did not accept the data (the second case shown in [Figure 29-51](#)).

The USB host need not send a whole RX FIFO worth of data to the endpoint during an OUT transaction. In this case, the RX FIFO is not full when the endpoint RX interrupt is generated. The CPU code must be careful not to read too much data. CPU code must read RXFSTAT.RXF\_COUNT value before reading data from the RX FIFO.

At the end of an USB OUT transaction to an endpoint where the data is accepted (ACKed), the hardware clears the endpoint STAT\_FLG.FIFO\_EN bit. Once the CPU software has dealt with the OUT transaction data in the endpoint RX FIFO, it must re-enable the endpoint OUT transaction reception by setting the endpoint CTRL.SET\_FIFO\_EN bit. CPU software can use the endpoint CTRL.SET\_FIFO\_EN bit as a receive flow control mechanism.

#### 29.3.3.1.1 Acknowledged Transactions (ACK)

At completion of an OUT transaction to an endpoint, the USB module issues an endpoint-specific interrupt to the CPU and STAT\_FLG is updated. In response to the endpoint interrupt, the CPU must read EPN\_STAT register to identify the endpoint causing the interrupt, then write a 1 to the interrupt bit to clear it. The CPU must then set EP\_NUM.EP\_NUM to the endpoint number and EP\_NUM.EP\_SEL to 1, and then read the endpoint status from STAT\_FLG. STAT\_FLG.ACK is set to indicate that the endpoint received a transaction to which the USB module signaled ACK handshaking.

If STAT\_FLG.FIFO\_EMPTY is cleared, the transaction sent 1 or more bytes of data (but less than or equal to the physical size of the endpoint RX FIFO), and the data is in the endpoint RX FIFO. The CPU knows the number of bytes to read from RX FIFO by reading RXFSTAT.RXF\_COUNT value. The CPU can then read RX data from DATA register. Once the CPU has read the data from the FIFO, it sets the CTRL.SET\_FIFO\_EN bit to allow the next USB OUT transaction to the endpoint to be placed into the RX FIFO, and then clears the EP\_NUM.EP\_SEL bit. This clears the STAT\_FLG.ACK bit for this endpoint to allow next transaction status to be written into the STAT\_FLG register.

#### 29.3.3.1.2 Non-Acknowledged Transactions (NAK)

The device can be configured via the SYSCON1.NAK\_EN either to inform the CPU of a NAKed transaction or not. If SYSCON1.NAK\_EN is cleared, no interrupt is asserted to the CPU if an OUT transaction completes with a NAK handshake and STAT\_FLG.NAK bit is not set. If SYSCON1.NAK\_EN is set, the USB module issues an endpoint-specific interrupt to the CPU at completion of an OUT transaction to an endpoint, and STAT\_FLG.NAK bit is set. In response to the endpoint interrupt, the CPU must read EPN\_STAT register to identify the endpoint causing the interrupt, and then write a 1 to the interrupt bit to clear it. The CPU must then set EP\_NUM.EP\_NUM to the endpoint number and EP\_NUM.EP\_SEL to 1, and then read the endpoint status from STAT\_FLG. STAT\_FLG.NAK is set to indicate that the endpoint received a transaction to which the USB module signaled NAK handshaking.

The CPU must set the CTRL.SET\_FIFO\_EN bit to allow the next USB OUT transaction to the endpoint to be placed into the RX FIFO, and then clear the EP\_NUM.EP\_SEL bit. This clears the STAT\_FLG.NAK bit for this endpoint to allow the next transaction status to be written into the STAT\_FLG register.

### 29.3.3.2 Non-Isochronous, Non-Control OUT Transaction Error Conditions

#### 29.3.3.2.1 STALLed Transactions

The USB module responds to an endpoint OUT transaction with a STALL handshake to indicate an error condition on the endpoint either if the endpoint STAT\_FLG.EP\_HALTED bit is set or if a request error occurs (control transactions only). When an endpoint OUT transaction is given a STALL handshake, the endpoint STAT\_FLG.STALL bit is set and an endpoint-specific interrupt is generated for the endpoint. STAT\_FLG.FIFO\_EN is of lower priority than STAT\_FLG.EP\_HALTED; when the STAT\_FLG.EP\_HALTED bit is set and transactions to the RX endpoint are stalled, regardless of the STAT\_FLG.FIFO\_EN value. If STAT\_FLG.FIFO\_EN is set, the STAT\_FLG.FIFO\_EN bit is automatically cleared at the end of the STALLed transaction and RX FIFO is cleared.

In response to the endpoint interrupt, the CPU must read the EPN\_STAT register to identify the endpoint causing the interrupt, and then write a 1 to the interrupt bit to clear it. The CPU must then set EP\_NUM.EP\_NUM to the endpoint number and EP\_NUM.EP\_SEL to 1, and then read the endpoint status from STAT\_FLG. STAT\_FLG.STALL is set to indicate that the endpoint received a transaction to which the USB module signaled STALL handshaking.

If STAT\_FLG.EP\_HALTED has been set by the CPU and can be removed, the CPU must set CTRL.CLR\_HALT to clear the condition and set CTRL.SET\_FIFO\_EN to allow the next USB OUT transaction to the endpoint to be placed into the RX FIFO. If STAT\_FLG.EP\_HALTED has been set in response to a SET\_FEATURE request sent by the USB host, or if the bit is cleared (control transaction only), the CPU has no action to perform and must clear the EP\_NUM.EP\_SEL bit. This clears the STAT\_FLG.STALL bit for this endpoint and allows the next transaction status to be written into the STAT\_FLG register.

#### 29.3.3.2.2 Packet Errors

In case of a receive data error during an endpoint OUT transaction (token or data packet), the USB module does not provide a handshake during the handshake phase of the transaction and no interrupt is asserted to the CPU (the fourth case shown in [Figure 29-51](#)). Additionally, the endpoint RX FIFO is not filled, and STAT\_FLG.FIFO\_EN bit is not cleared. If the CPU clears the RX FIFO during the data packet of an OUT transaction, no handshake is returned to the USB host to signal an error.

#### 29.3.3.2.3 Sequence Bit Errors

If the core does not receive expected DATA PID during an OUT transaction, the module automatically returns ACK handshake to the USB host, regardless of the STAT\_FLG.FIFO\_EN bit (per the USB specification). Data is ignored, and no interrupt is asserted to the CPU.

This error occurs if ACK handshake from previous OUT transaction is received corrupted by the USB host.

### 29.3.3.3 Non-Isochronous, Non-Control OUT Endpoint FIFO Error Conditions

If the USB host attempts to fill more data into an endpoint RX FIFO than the FIFO can hold, a FIFO overrun occurs. The USB module does not provide a handshake during the handshake phase of the transaction and no interrupt is asserted to the CPU. Additionally, the endpoint RX FIFO is not filled, and STAT\_FLG.FIFO\_EN bit is not cleared.

The CPU must not read more data from RX FIFO than the value indicated by RXFSTAT.RXF\_COUNT.

### 29.3.4 Non-Isochronous IN (CPU→USB HOST) Transactions

Non-isochronous IN transactions refer to USB transactions in which data is moved from the CPU to the USB host, where the USB handshaking protocols are in effect, and data transmission is ensured. These transactions are the IN transactions that occur on control, bulk, and interrupt endpoints. These transactions do not ensure USB bandwidth.

To provide data for an endpoint IN transaction, the CPU code writes the transmit data into the endpoint transmit FIFO. CPU code must first wait until the USB is done with any previous TX data for the endpoint (if data had previously been written to the TX FIFO). This must be done by proper response to endpoint-specific transmit interrupts. When an IN transaction to the endpoint occurs, if the endpoint `STAT_FLG.FIFO_EN` bit is set, the USB module sends any data that is in the endpoint TX FIFO during the data phase. If the TX FIFO is empty and `STAT_FLG.FIFO_EN` is set when an IN transaction to the endpoint occurs, a 0-byte data packet is sent.

Once the endpoint previous transmit activity is taken care of, the CPU code gains access to endpoint FIFO and status by setting the `EP_NUM.EP_SEL` bit. Then the CPU can write the new transmit data to the endpoint TX FIFO via the `DATA` register (being careful not to overflow the FIFO). Once all of the transmit data has been written to the endpoint FIFO, CPU code sets the `CTRL.SET_FIFO_EN` bit to allow the USB to use the endpoint TX FIFO, and then clears the `EP_NUM.EP_SEL` bit. The data in the endpoint TX FIFO is sent to the USB host the next time an IN transaction to the endpoint occurs.

Figure 29-52 shows the various USB protocol conditions that can occur during non-isochronous IN transactions. It diagrams the three phases of the IN transaction, the direction of information flow for each phase, when endpoint-specific interrupts are generated, and the resulting `STAT_FLG` bits for the endpoint. The top three cases show the normal USB handshaking: acknowledge (data sent by USB module and received properly by the USB host), NAK (device not ready to send data to USB host), and STALL (device in a condition where the endpoint cannot handle IN transactions). The last case shows an abnormal case in which there is an error either in the token packet received by the core or in the data packet received by the USB host.

#### 29.3.4.1 Non-Isochronous IN Endpoint Handshaking

Per USB specifications for IN transactions, the USB host can provide only one of two handshakes to the USB function during the handshake phase: ACK or no handshake at all. The first indicates successful transfer (first case shown in Figure 29-52), and the second indicates that the host received a garbled data packet (last case shown in Figure 29-52).

##### 29.3.4.1.1 Acknowledged Transactions (ACK)

When the endpoint IN transaction completes on the USB bus with an ACK handshake, the endpoint generates an endpoint-specific interrupt to the CPU (see first case in Figure 29-52). In response to the endpoint interrupt, the CPU must read the `EPN_STAT` register to identify the endpoint causing the interrupt, and then write a 1 to the interrupt bit to clear it. The CPU must then set `EP_NUM.EP_NUM` to the endpoint number, `EP_NUM.EP_DIR` to 1 (to signal an IN endpoint), and `EP_NUM.EP_SEL` to 1, and then read the endpoint status from `STAT_FLG`. `STAT_FLG.ACK` is set to indicate that the endpoint received an ACK handshake from the USB host, and the TX FIFO is empty (because any data that was in the TX FIFO was transmitted during the IN transaction).

If the CPU has more data to transmit to the USB host, it must fill the TX FIFO following the process indicated above. It must then clear `EP_NUM.EP_SEL` bit. This clears the `STAT_FLG.ACK` bit for this endpoint to allow next transaction status to be written into the `STAT_FLG` register.

**Figure 29-52. Non-Isochronous IN Transaction Phases and Interrupts**

Successful data transfer to USB Host. (Endpoint STAT\_FLG.FIFO\_EN bit was set when token was received.)

After interrupt, EP's TX FIFO is empty.

STAT\_FLG bits after interrupt

| EP_Halted | STALL | NAK | ACK |
|-----------|-------|-----|-----|
| 0         | 0     | 0   | 1   |

No data transmitted by the LH. (Endpoint STAT\_FLG.FIFO\_EN bit was clear when token was received.)

EP TX FIFO is unchanged by this USB transaction.

STAT\_FLG bits after interrupt  
(SYSCON1.Nak\_En=1)

| EP_Halted | STALL | NAK | ACK |
|-----------|-------|-----|-----|
| 0         | 0     | 1   | 0   |

EP stalled. No data transmitted by the LH. (Endpoint STAT\_FLG.EP\_HALTED bit was set when token was received or an EPO control request error has occurred.)

EP TX FIFO is cleared by this USB transaction.

STAT\_FLG bits after interrupt

|    | EP_Halted | STALL | NAK | ACK |
|----|-----------|-------|-----|-----|
| or | 1         | 1     | 0   | 0   |
|    | 0         | 1     | 0   | 0   |

EP TX Data Error during transmission.

EP TX FIFO is unchanged by this USB transaction. No interrupt occurs. STAT\_FLG is unchanged.

 Indicates a packet received by the device

 Indicates a packet sent by the device

### 29.3.4.1.2 Non-Acknowledged Transactions (NAK)

For the case in which the CPU is not ready to provide transmit data for transactions to an IN endpoint, the core provides a NAK handshake to the host for any USB IN transaction to that endpoint. Readiness to transmit data is signaled via the endpoint `STAT_FLG.FIFO_EN` bit; when 1 it indicates that data in the TX FIFO can be sent to the USB host. When the endpoint `STAT_FLG.FIFO_EN` bit is 0 and an IN transaction to the endpoint occurs, NAK handshake is sent, indicating that the CPU is not ready to handle the request.

If `SYSCON1.NAK_EN` bit is cleared, when the NAK handshake is sent in the data packet portion of the transaction to the IN endpoint, `STAT_FLG` is not updated and no endpoint-specific interrupt to the CPU is generated. If the `SYSCON1.NAK_EN` bit is set, when the NAK handshake is sent in the data packet portion of the transaction to the IN endpoint, the `STAT_FLG.NAK` bit is set and an endpoint-specific interrupt to the CPU is generated.

In response to the endpoint interrupt, the CPU must read the `EPN_STAT` register to identify the endpoint causing the interrupt, and then write a 1 to the interrupt bit to clear it. The CPU must then set `EP_NUM.EP_NUM` to the endpoint number, `EP_NUM.EP_DIR` to 1 (to signal an IN endpoint), and `EP_NUM.EP_SEL` to 1, and then read the endpoint status from `STAT_FLG`. `STAT_FLG.NAK` is set to indicate that the endpoint sent a NAK handshake to the USB host. If the CPU has data to transmit to the USB host, it must fill the TX FIFO following the process indicated above. The CPU must then clear the `EP_NUM.EP_SEL` bit. That clears the `STAT_FLG.NAK` bit for this endpoint to allow the next transaction status to be written into the `STAT_FLG` register. Signaling NAK does not cause the endpoint TX FIFO to be cleared (because the CPU still retains control of the FIFO).

Signaling NAK handshake for several endpoint transactions in a row can cause the PC host to discard the transaction, so NAK is not necessarily a good mechanism in cases where the CPU is not able to service a request for long periods of time.

## 29.3.4.2 Non-Isochronous IN Transaction Error Conditions

### 29.3.4.2.1 STALLed Transactions

The USB module sends a STALL handshake to the USB host during the data phase of the transaction to the IN endpoint either if the endpoint `STAT_FLG.EP_HALTED` flag is set, or if a request error occurs (control transaction only). A USB STALL handshake indicates that the device endpoint is in a condition in which it is not able to transfer data and instructs the USB host not to retry the transaction. The device typically requires intervention via some other mechanism to clear the condition, usually a control transfer via endpoint 0. The CPU can set the endpoint `EP_HALTED` bit by selecting the endpoint by writing the appropriate value in `EP_NUM` register, and then setting the endpoint `CTRL.Set_HALT` bit, and clear it by selecting the endpoint, and then setting the endpoint `CTRL.Clr_HALT` bit. When the endpoint `EP_HALTED` bit is set, the endpoint signals STALL for its IN transactions until the HALT condition is cleared. When the STALL handshake is sent in response to a transaction to the endpoint, the `STAT_FLG.STALL` bit is set, and an endpoint-specific interrupt to the CPU is generated.

In response to the endpoint interrupt, the CPU must read the `EPN_STAT` register to identify the endpoint causing the interrupt, and then write a 1 to the interrupt bit to clear it. The CPU must then set `EP_NUM.EP_NUM` to the endpoint number, `EP_NUM.EP_DIR` to 1 (to signal an IN endpoint), and `EP_NUM.EP_SEL` to 1, and then read the endpoint status from `STAT_FLG`. `STAT_FLG.STALL` is set to indicate that the endpoint sent a STALL handshake to the USB host. The CPU must then clear `EP_NUM.EP_SEL` bit. This clears the `STAT_FLG.STALL` bit for this endpoint and allows the next transaction status to be written into the `STAT_FLG` register.

Except for control endpoint 0, separate endpoint halt bits are defined for each direction; so for a given endpoint number, the TX can be halted when the RX is not.

### 29.3.4.2.2 Packet Errors

If an error (CRC, bit stuffing, or PID check) occurs during the token packet of a USB IN transaction to a non-isochronous endpoint, the USB block ignores the transaction. No endpoint-specific interrupt to the CPU occurs for transactions with corrupted packets. If the CPU clears the TX FIFO during the data packet of an IN transaction, a bit stuffing error is forced.

If the USB host returns no handshake after an IN transaction (in case of an error during transmission), the USB device controller module detects after a time-out that an error has occurred. The data to transmit is still in the TX FIFO to be re-sent during next IN transaction, STAT\_FLG.FIFO\_EN is not cleared, and no interrupt is asserted to the CPU.

### 29.3.4.3 Non-Isochronous IN Endpoint FIFO Error Conditions

The CPU cannot write more data into the TX FIFO than the configured FIFO size.

## 29.3.5 Isochronous OUT (USB HOST→CPU) Transactions

Isochronous OUT transactions are USB transactions in which a given amount of data is transferred from the USB host to the USB device controller module device every 1-ms USB frame. No USB handshaking is provided, and no endpoint-specific interrupt to the CPU is generated at completion of an isochronous OUT transaction. The CPU is responsible for handling isochronous OUT data at each start of frame (SOF) interrupt.

At every SOF interrupt, for each isochronous OUT endpoint, CPU code must select the endpoint by writing the appropriate value in the EP\_NUM register and check STAT\_FLG.ISO\_FIFO\_EMPTY. If the RX FIFO contains data, code must read the RXFSTAT.RXF\_COUNT value (if the number of bytes to read from RX FIFO is not known), read all the bytes from RX FIFO via the data register, and then clear the EP\_NUM.EP\_SEL bit.

Because the USB transaction for the isochronous endpoint can occur at any time during the USB 1-ms frame, the USB interface implements a double-buffering of the endpoint receive data FIFO. The endpoint includes two FIFOs, each of which is the length of the configured isochronous endpoint. At all times, one of the two FIFOs is foreground and the other is background. The USB interface side of the USB module is allowed to write to the background RX FIFO, and the CPU is allowed to read to the foreground RX FIFO. The designations foreground and background are swapped at each start of frame (SOF). Isochronous endpoint FIFOs in the background are always enabled to the USB, whereas the foreground FIFOs are enabled to the CPU.

[Figure 29-53](#) shows the two phases (ISO OUT token and data) of an isochronous OUT data transfer in the top portion of the figure. No endpoint-specific interrupt to the CPU is generated for the isochronous OUT transaction. The data for isochronous endpoints are instead handled by the CPU at each start of frame (SOF) interrupt, which is shown as the second case in [Figure 29-53](#).

**Figure 29-53. Isochronous OUT Transaction Phases and Interrupts**

Successful data transfer from USB Host

No handshake occurs. EP RX FIFO contains received data after data packet completes. No interrupt occurs.

Reception of SOF causes SOF interrupt.

Note: An SOF interrupt is generated even if the SOF packet is corrupted.

LH code for SOF interrupt service routine must fill all isochronous in EP TX FIFOs with new transmit data and pull new receive data from all Isochronous Out EP RX FIFOs.

### 29.3.5.1 Isochronous OUT Endpoint Handshaking

Because isochronous endpoint transactions have no handshake packets, the STAT\_FLG.STALL, STAT\_FLG.NAK, and STAT\_FLG.ACK bits for isochronous endpoints always return 0. Because there is no handshake, the endpoint-specific interrupt for isochronous endpoints is not used.

### 29.3.5.2 Isochronous OUT Transaction Error Conditions

If the CPU fails to read all of the data in the ISO OUT endpoint foreground FIFO by the time the foreground and background FIFOs are switched (at the next SOF), the endpoint FIFO that is being switched to the background is flushed, and the STAT\_FLG.DATA\_FLUSH bit is asserted for the duration of the next frame.

There is no special indication for the case in which the USB host does not provide a transaction to an ISO OUT endpoint during a frame, but once the FIFO that was background in that frame is foreground, the FIFO is empty (a 0-length data ISO OUT transaction also results in an empty FIFO and cannot be distinguished from a missed ISO OUT transaction).

If an ISO OUT transaction occurs with data error (CRC, PID check, or bit stuffing), the RX FIFO is empty at the next SOF interrupt, and the STAT\_FLG.ISO\_ERR bit is asserted for the duration of the next frame.

### 29.3.5.3 Isochronous OUT Endpoint FIFO Error Conditions

The CPU must never read more data than the value given by RXFSTAT.RXF\_COUNT.

If the USB host sends more data than the FIFO can contain, the FIFO is cleared and the STAT\_FLG.ISO\_ERR is set at the next SOF interrupt. A properly configured USB system does not do this.

**NOTE:** Both foreground and background isochronous FIFOs are cleared when the CTRL.CLR\_EP bit is set.

### 29.3.6 Isochronous IN (CPU→USB HOST) Transactions

Isochronous IN transactions are USB transactions in which a given amount of data is transferred from the USB device controller module device to the USB host every 1-ms USB frame. No handshaking is provided.

The USB module provides double-buffering of data for ISO IN endpoints; the background FIFO is used as the source of data for IN transactions to the ISO endpoint, and the foreground FIFO can be written to by the CPU. When an IN transaction to an ISO endpoint occurs, the USB module sends all data found in the endpoint background TX FIFO. The CPU is responsible for providing new data to the isochronous IN endpoint foreground TX FIFO at each start of frame interrupt.

In response to the SOF interrupt, for each isochronous IN endpoint, CPU code selects the endpoint (via the EP\_NUM register), and then fills the endpoint TX FIFO (via the DATA register). Once all the transmit data have been written to the FIFO, the CPU code must clear the EP\_NUM.EP\_SEL bit.

Because the USB transaction for the isochronous endpoint can occur at any time during the USB 1-ms frame, the USB interface implements a double-buffering of the endpoint transmit data FIFO. The endpoint includes two FIFOs, each of which is the length of the configured isochronous endpoint. At all times, one of the two FIFOs is foreground and the other is background. The USB interface side of the USB module is allowed to read from the background TX FIFO, and the CPU is allowed to write to the foreground TX FIFO. The designations foreground and background are swapped, and the new background TX FIFO is cleared at each start of frame (SOF). Because ISO endpoints implement double-buffering, ISO endpoints do not control access to the FIFOs via a CTRL.SET\_FIFO\_EN bit; the CTRL.SET\_FIFO\_EN and the STAT\_FLG.FIFO\_EN bits are not implemented for ISO IN endpoints.

Figure 29-54 shows the transaction phases associated with isochronous IN transactions and the SOF transaction. No endpoint-specific interrupt to the CPU is generated as a result of an isochronous IN transaction, and there is no handshake phase. The SOF transaction causes an SOF interrupt to the CPU; it is assumed that the CPU refills the isochronous IN endpoint transmit FIFO at each SOF interrupt.

**Figure 29-54. Isochronous IN Transaction Phases and Interrupts**

### 29.3.6.1 Isochronous IN Endpoint Handshaking

Because isochronous endpoint transactions have no handshake packets, the STAT\_FLG.STALL, STAT\_FLG.NAK, and STAT\_FLG.ACK bits for isochronous endpoints always return 0. Because there is no handshake, there is no endpoint-specific interrupt to the CPU to report handshake results for isochronous endpoints.

### 29.3.6.2 Isochronous IN Transaction Error Conditions

If the USB host did not successfully complete an ISO IN transaction in the previous frame, and if data were present in TX FIFO to be sent at the IN transaction, the STAT\_FLG.MISS\_IN bit is asserted for the duration of the following frame. If the ISO IN endpoint is cleared in the middle of a USB transaction to the background FIFO, the macro forces a bit stuffing error for the ISO transaction.

### 29.3.6.3 Isochronous IN Endpoint FIFO Error Conditions

If the CPU attempts to overfill the configured endpoint FIFO, data written to DATA register after the TX FIFO is full is lost, but any data that was successfully put into the FIFO is transmitted when that FIFO is the background FIFO and an IN transaction for that endpoint occurs. Because an ISO TX FIFO is cleared automatically on the toggle from background to foreground, there is no reason to clear the FIFO. However, if the CPU does not wish to send the data it wrote, clearing the endpoint is the only mechanism to do this.

## 29.3.7 Control Transfers on Endpoint 0

Control transfers on endpoint 0 include control write and control read transfers. Control write and control read transfers are each composed of two or more transactions to endpoint 0. Additionally, the USB device controller module is capable of autodecoding some control write and control read transfers. These operations are summarized in [Figure 29-55](#) and [Figure 29-56](#). An IN or an OUT transaction is received out of a control request. This transaction is automatically stalled by the core.

Non-autodecoded control read and control write transfers are sets of transactions that occur on endpoint 0 and have specific USB protocol meaning but are not handled automatically by the core. The USB device controller block automatically provides an ACK handshake for the setup stage transaction, but the data and status stage transaction handshaking is accomplished using the usual RX and TX control bits that affect transaction handshaking. A general USB interrupt to the CPU occurs at the end of each transaction of each stage of a control transfer. The CPU must perform the following actions to act on non-autodecoded control transfers:

- Process the setup phase setup USB interrupt. The CPU reads the control transfer command from the setup FIFO and decodes the command. For control reads, the CPU fetches the requested read data and places it (or as much of the read data as fits) into the endpoint 0 FIFO, and then enables the endpoint 0 FIFO. For control writes, the CPU code only enables the endpoint 0 FIFO. CPU code also sets any flags needed for processing endpoint 0 USB interrupts during the control transfer.
- Process the data phase endpoint 0 general USB interrupt(s). For control reads, the data phase general USB endpoint 0 TX interrupt indicates that the previously provided transmit data has been sent. Any additional data must be written to the endpoint 0 FIFO. For control writes, the write data must be pulled from the endpoint 0 FIFO, and when all control write data is available, interpret the write data and act on the write request. After handling the last data phase interrupt, the CPU must set the endpoint 0 control bits to signal the desired status to the host.
- Process the status stage endpoint 0 general USB interrupt. The CPU provides its completion status back to the USB host during this stage, either via status in the data phase of the transaction (for control write transfers) or via the handshake phase of the transaction (for control read transfers).

**Figure 29-55. Stages and Transaction Phases of Autodecoded Control Transfers**

**Figure 29-56. Stages and Transaction Phases of Non-Autodecoded Control Transfers**

Autodecoded control read and control write transfers are sets of transactions that occur on endpoint 0 that have specific USB protocol meaning and are handled automatically by the USB device controller block without any intervention by the CPU. The USB device controller block handles all handshaking automatically and without regard to the endpoint 0 control bits that affect normal (non-control transfer) transaction handshaking. No interrupt is asserted to the CPU during autodecoded control transfers.

If no USB1.1 specification defined request is associated with the data of the setup phase, request is stalled by the core and the CPU is not informed of its occurrence (autodecoded).

When a setup token is identified, the USB decode module must monitor the setup stage data packet, decode it, and determine whether it is an autodecoded or a non-autodecoded transfer and a control read or a control write. If it is a valid non-autodecoded request, the setup FIFO is immediately cleared and control of the FIFO is immediately taken away from the CPU (if the CPU had control of the FIFO). New setup data are placed into the setup FIFO, and the setup interrupt flag is set (IRQ\_SRC.setup).

In response to the setup interrupt, the CPU must select the setup FIFO by setting the EP\_NUM.SETUP\_SEL bit. This clears the IRQ\_SRC.SETUP flag. The CPU must then read 8 bytes from the setup FIFO, clear the EP\_NUM.SETUP\_SEL bit, and confirm that IRQ\_SRC.SETUP bit has not been reset by a new setup transaction. If the IRQ\_SRC.SETUP flag is asserted, the CPU must discard the previously read data and handle the new setup packet as explained above. Thus the CPU never misses a new occurring setup transaction (per USB 1.1 specification).

#### **29.3.7.1 Autodecoded Control Write Transfers**

For set address control write transfers, the USB address provided in the setup token is captured to the USB module device address register. If new address is different from 0, the device moves into addressed state (DEVSTAT.ADD set) if it was not already addressed.

For set and clear feature control writes, the appropriate feature information bit is set or cleared. When a set or clear feature transfer occurs to set or clear the device remote wake-up feature, the DEVSTAT.R\_WK\_OK bit is set or cleared, as appropriate. If a set or clear interface feature occurs, the request is automatically stalled by the core because no feature is defined for interface (see the USB 1.1 specification).

Per the USB 1.1 specifications, a SET\_ADDRESS request is effective after the status stage of the request, even if the status stage does not end with an ACK handshake. SET/CLEAR\_FEATURE requests are effective after setup stage, even if no status stage occurs.

##### **29.3.7.1.1 Autodecoded Control Write Transfer Handshaking**

The USB device controller module automatically provides ACK handshaking for all transactions of all stages of autodecoded control write transfers, except if a corrupted packet is received, which the USB module ignores. The CTRL.SET\_FIFO\_EN and SYSCON2.STALL\_CMD bits have no effect on handshaking.

##### **29.3.7.1.2 Autodecoded Control Write Transfer Error Conditions**

If the token packet or the data packet of a setup stage transaction has an error (bad CRC, PID check, or bit stuffing error), the USB block ignores the transaction. The USB block does not provide ACK handshaking in this case.

### 29.3.7.2 Autodecoded Control Read Transfers

Autodecoded control reads include the standard device requests GET\_ENDPOINT and DEVICE\_STATUS. These control read transfers access information that is kept in registers inside the USB module, so CPU code is not involved in filling the read data into the TX FIFO.

The USB module returns the currently selected appropriate status information (depending on the wIndex value in the setup stage data packet) during the data phase of the single IN transaction of the data stage, and provides ACK as the handshake for the status stage handshake phase. The CPU receives no interrupt.

#### 29.3.7.2.1 Autodecoded Control Read Transfer Handshaking

The USB device controller module automatically provides ACK handshaking for all transactions of all stages of autodecoded control read transfers, except if a corrupted token packet is received, which the USB module ignores. The CTRL.FIFO\_EN and SYSCON2.STALL\_CMD bits have no effect on the handshaking. If the status packet has a DATA0 PID instead of a DATA1 PID, status is STALLED and no interrupt is asserted to the CPU. If the setup packet has a DATA1 PID instead of a DATA0 PID, setup transaction is ignored (error).

#### 29.3.7.2.2 Autodecoded Control Read Transfer Error Conditions

If the token phase or the data phase of a setup stage transaction has an error (bad CRC, PID check, or bit stuffing error), the USB block ignores the transaction. The USB block does not provide ACK handshaking in this case.

Data errors during the data stage of autodecoded control write transfers are handled in the standard way; any data stage transaction from the host where a data error occurs is ignored.

It is possible that the USB host sends a GET\_ENDPOINT/DEVICE\_STATUS request with a bad parameter. If the autodecode mechanism senses a bad parameter in the setup stage data phase, the autodecode mechanism causes a STALL handshake to be signaled during the data phase of the data stage and during the status stage.

### 29.3.7.3 Non-Autodecoded Control Write Transfers

Non-autodecoded control write transfers include the SET\_/CLEAR\_ENDPOINT feature, SET\_CONFIGURATION, SET\_INTERFACE, SET\_DESCRIPTOR and class- or vendor-specific control write transfers. Non-autodecoded control write transfers consist of two or three stages [setup, data (optional), and status].

The setup stage of a valid non-autodecoded control write transfer consists of one SETUP transaction from USB host to USB device. At the end of the setup stage handshake, the USB module generates an CPU general USB interrupt with the IRQ\_SRC.SETUP flag set. The CPU must respond to this general USB interrupt by setting EP\_NUM.SETUP\_SEL bit, which clears the setup interrupt flag. The CPU must then read 8 bytes from the setup FIFO via the DATA register, clear EP\_NUM.EP\_SEL bit, and check the IRQ\_SRC.SETUP flag. If the IRQ\_SRC.SETUP flag is set, the CPU must discard the setup data it has just read and handle the new setup data packet following the same scheme. If the IRQ\_SRC.SETUP flag is cleared, the CPU code interprets this request information and performs any application-specific activity needed because of the setup stage request. If there is one or more data stage for the transfer, the CPU must set the CTRL.SET\_FIFO\_EN bit for endpoint 0 to allow the core to accept RX data from the coming OUT transaction.

The data stage for non-autodecoded control writes consists of zero or more OUT transactions. Transaction handshaking and interrupt generation as for non-isochronous, non-control OUT endpoints applies. The CPU can cause NAK, STALL, or ACK signaling for the data stage transactions. If ACK was signaled on a given general USB interrupt, the CPU must respond by reading the data from the endpoint 0 RX FIFO and saving it for processing.

After completion of the data stage, a status stage IN transaction occurs. The USB module provides handshaking to the USB host based on the endpoint 0 handshaking control bit `STAT_FLG.FIFO_EN`. The CPU can delay signaling completion of the control write transfer by forcing NAK handshaking to the host during the status stage (by holding `STAT_FLG.FIFO_EN` 0), or causing ACK handshaking by setting the `CTRL.SET_FIFO_EN` bit with an empty endpoint 0 FIFO. An endpoint 0 TX general USB interrupt is sent to the CPU at completion of the status stage.

After a `SET_CONFIGURATION` request, the device moves in addressed or configured state as soon as the CPU sets the `SYSCON2.DEV_CFG` or `SYSCON2.CLR_CFG` bits.

### 29.3.7.3.1 Specific CPU Required Actions

If the device receives a valid set endpoint halt feature request, it must set the appropriate `CTRL.SET_HALT` control bit.

If the device receives a valid `CLEAR_ENDPOINT` halt feature request, it must set the appropriate `CTRL.RESET_EP` bit to clear the halt condition, FIFO flags, and reset data PID to `DATA0` for the endpoint. If the specified endpoint number is 0, the CPU has only to set `CTRL.CLR_HALT` bit to clear the halt condition.

If the device receives a valid `SET_CONFIGURATION` request, it must reset all endpoints by setting the `CTRL.RESET_EP` control bits, set the `SYSCON1.SELF_PWR` bit to the appropriate value, and then set halt conditions for endpoints not used by the default interface set for the configuration. If the device was addressed when the `SET_CONFIGURATION` was received, the CPU must write 1 to the `SYSCON2.DEV_CFG` bit to allow the device to move into the configured state (`DEVSTAT.CFG` bit set). If the device was configured when the `SET_CONFIGURATION` was received, and the new configuration value is 0, the CPU must write 1 to the `SYSCON2.CLR_CFG` bit to allow the device to move back into the addressed state (`DEVSTAT.CFG` bit cleared).

If the device receives a valid set interface request, it must reset all endpoints used by the interface set, by setting `CTRL.RESET_EP` control bits, and then set halt conditions for endpoints not used by this interface.

Other CPU required actions are specific to the request and not detailed in this document.

### 29.3.7.3.2 Non-Autodecoded Control Write Transfer Handshaking

Setup stage transactions that are valid are signaled ACK. Transactions with invalid setup stage token or data packets are ignored and receive no handshake packet from the USB module, and there is no interrupt generated.

Data stage handshaking for non-autodecoded control write transfers is dependent on the endpoint 0 `STAT_FLG.FIFO_EN`, `STAT_FLG.EP_HALTED`, and `SYSCON2.STALL_CMD` bits. The CPU can delay completion of any transaction of the data stage by signaling NAK (via `CTRL.SET_FIFO_EN` bit not set). The USB specification requires that once `STALL` is signaled in a control transfer, it must be signaled on that endpoint until the next setup token is received. Either the `SYSCON2.STALL_CMD` or the `CTRL.SET_HALT` (reflected in the `STAT_FLG.EP_HALTED` register bit) register bits provide this functionality. `STAT_FLG.EP_HALTED` does not reflect the forced `STALL` caused by `SYSCON2.STALL_CMD`; it retains its previous value.

Status stage handshaking is controlled by the endpoint 0 `STAT_FLG.FIFO_EN` and `SYSCON2.STALL_CMD` bits. Successful completion of a non-autodecoded control write transfer is indicated by the USB device controller module returning a zero length data payload for the data phase of the status stage and an ACK handshake from the host for the handshake phase of the status stage. Although NAK handshaking can be used to indicate delays in completion of the requested control write, the USB host can choose to abort the control write after some number of NAKs.

### 29.3.7.3.3 Non-Autodecoded Control Write Transfer Error Conditions

If an error occurs while dealing with the control write, which the CPU cannot deal with itself, it must signal `STALL` to the USB host for all subsequent transactions until a new setup token to endpoint 0 occurs. This is true for both data stage and status stage transactions. This is most conveniently done by setting endpoint 0 `SYSCON2.STALL_CMD` bit, which causes stalling of all the remaining transactions of all remaining stages of a non-autodecoded control transfer, up to the reception of the next valid `SETUP` command.

Error conditions are handled as for BULK/INTERRUPT transactions. If a packet is received corrupted, the core ignores the transaction and no interrupt is asserted.

#### 29.3.7.4 Non-Autodecoded Control Read Transfers

Non-autodecoded control read transfers include the GET\_INTERFACE\_STATUS, GET\_CONFIGURATION, GET\_INTERFACE, GET\_DESCRIPTOR, SYNCH\_FRAME and class- or vendor-specific control read transfers. Non-autodecoded control read transfers consist of three stages (setup, data, and status).

The setup stage of a valid non-autodecoded control read transfer consists of one SETUP transaction from USB host to USB device. At the end of the setup stage handshake, the USB module generates a CPU general USB interrupt with the IRQ\_SRC.SETUP flag set. The CPU must respond to this general USB interrupt by setting the EP\_NUM.SETUP\_SEL bit, which clears the setup interrupt flag. The CPU must then read 8 bytes from the setup FIFO via the DATA register, clear the EP\_NUM.EP\_SEL bit, and check the IRQ\_SRC.SETUP flag. If the IRQ\_SRC.SETUP flag is set, the CPU must discard the setup data it has just read and handle the new setup data packet following the same scheme. If the IRQ\_SRC.SETUP flag is cleared, the CPU code interprets this request information and then prepares data for the IN transaction that follow. This includes placing the data being requested (or the first few bytes, if more than one FIFO worth of data is being returned) into the endpoint 0 FIFO, and setting the CTRL.SET\_FIFO\_EN bit.

The data stage of a control read transfer consists of one or more IN transactions. Transaction handshaking and interrupt generation as for non-isochronous, non-control IN endpoints applies; the CPU can cause NAK, STALL, or ACK signaling for the data stage transactions. At endpoint 0 TX general USB interrupts, CPU code must move more data to the endpoint 0 FIFO, until the last bytes of the requested data have been provided. Although SETUP packets have a defined payload length, the USB host can cancel the transaction at any time, without the status stage, and resend another SETUP command. The CPU code must be able to operate correctly in this situation.

After completion of the data stage, a status stage OUT transaction occurs. The USB host sends a zero-length data packet, and the CPU code must return its completion status for the control read standard request via standard handshaking mechanisms.

---

**NOTE:** In the case of returning exactly what the host requested and that request was a multiple of the maximum packet size, no zero-length packet is required. A zero-length packet is required only when the amount of data the device has to return is less than the amount requested by the host and the amount returned is a multiple of the maximum packet size (source USB forum).

---

##### 29.3.7.4.1 Non-Autodecoded Control Read Transfer Handshaking

Handshaking for the setup stage of non-autodecoded control read transfers is forced by the USB module to always be ACK, unless there is a data error in the packet, in which case the USB module ignores the transaction. If the setup packet has a DATA1 PID instead of a DATA0 PID, the setup transaction is ignored (error).

Data stage handshaking for non-autodecoded control read transfers is dependent on the endpoint 0 STAT\_FLG.FIFO\_EN, STAT\_FLG.EP\_HALTED, and SYSCON2.STALL\_CMD bits. The handshaking information is used during the data phase of the data stage transaction. The USB specification requires that once STALL is signaled in a control transfer, it must be signaled until the next setup token is received. The SYSCON2.STALL\_CMD and CTRL.SET\_HALT (reflected through the STAT\_FLG.EP\_HALTED register bit) register bits provide this functionality. STAT\_FLG.EP\_HALTED does not reflect the forced STALL caused by SYSCON2.STALL\_CMD; it retains its previous value.

The status stage is controlled by the CTRL.FIFO\_EN and SYSCON2.STALL\_CMD bits.

Successful completion of non-autodecoded control read transfers is indicated by the host sending an OUT token followed by an empty packet and the USB device controller responding with ACK. If the data packet sent by the USB host during the status stage of a control read request is not empty, the OUT transaction is accepted by the core, but OUT data is not put into the endpoint 0 RX FIFO. If the status packet has a DATA0 PID instead of a DATA1 PID, a STALLED is returned by the core and an interrupt is asserted.

### 29.3.7.4.2 Non-Autodecoded Control Read Transfer Error Conditions

If an error occurs while dealing with the control read, which the CPU cannot deal with itself, it must signal STALL to the USB host for all subsequent transactions until a new setup token to endpoint 0 occurs. This is true for both data stage and status stage transactions. This is most conveniently done by setting endpoint 0 SYSCON2.STALL\_CMD bit, which causes stalling of all the remaining transactions of all remaining stages of a non-autodecoded control transfer, up to the reception of the next valid SETUP command.

Error conditions are handled as for BULK/INTERRUPT transactions. The USB device controller module responds to control read status stage transactions that have a bad token or bad data by not sending a handshake packet. In both cases, the transaction is ignored and no general USB interrupt is generated to the CPU.

### 29.3.7.5 Autodecoded Versus Non-Autodecoded Control Requests

**Table 29-55. Autodecoded Versus Non-Autodecoded Control Requests** <sup>(1)</sup> <sup>(2)</sup> <sup>(3)</sup> <sup>(4)</sup>

| Request           | Recipient | Status                                             | CPU Required Action                                                                                                                                                                                                                                                                                                                      | Device Behavior if Device Is Not Configured                                                                                                                                                                         |
|-------------------|-----------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET_STATUS        | Device    | Autodecoded (function of AUTODEC_DIS register bit) | None                                                                                                                                                                                                                                                                                                                                     | Device status is returned (SYSCON1.SELF_PWR and DEVSTAT.R_WK_OK bits).                                                                                                                                              |
|                   | Interface | Non-autodecoded                                    | The CPU must stall the command (via SYSCON2.STALL_CMD bit) if interface number is not correct. No feature is defined for interface.                                                                                                                                                                                                      | Command is passed to the CPU.                                                                                                                                                                                       |
|                   | Endpoint  | Autodecoded(function of AUTODEC_DIS register bit)  | None                                                                                                                                                                                                                                                                                                                                     | The core automatically stalls the command if endpoint number is different from 0.                                                                                                                                   |
| CLEAR/SET FEATURE | Device    | Autodecoded (function of AUTODEC_DIS register bit) | None (DS_CHG IT is asserted to the CPU after any DEVSTAT.R_WK_OK bit modification).                                                                                                                                                                                                                                                      | The core handles the request.                                                                                                                                                                                       |
|                   | Interface | Autodecoded (function of AUTODEC_DIS register bit) | None. (No feature is defined in USB 1.1 spec for interface. These requests are stalled).                                                                                                                                                                                                                                                 | Command is stalled anyway.                                                                                                                                                                                          |
|                   | Endpoint  | Non-autodecoded                                    | The CPU must stall the command (via SYSCON2.STALL_CMD bit) if endpoint number/type/direction is not correct. The CPU must reset the EP after having handled the pending transactions (if CLEAR) or set halt condition (if SET). For EP 0, CPU must only clear or set halt condition; FIFO and data PID is always correct for next setup. | Command is passed to the CPU.                                                                                                                                                                                       |
| SET_ADDRESS       | Device    | Autodecoded                                        | None (see <sup>(5)</sup> ) (Whether the device is addressed or not is available in DEVSTAT register. A valid SET_ADDRESS request with address number from 0 generates a DS_CHG interrupt to the CPU).                                                                                                                                    | Default: device moves in the addressed state if address number is different from 0. Addressed: device takes the new address value or moves in default state if address number is 0. Configured: request is STALLED. |

<sup>(1)</sup> Transactions on endpoints other than zero are ignored if the device is not configured (addressed state).

<sup>(2)</sup> If some endpoints are not used by the interface currently set, transactions on these endpoints are not ignored; the CPU must set halt feature for the endpoint. This does not happen if USB host works correctly.)

<sup>(3)</sup> If endpoint 0 is halted, per *USB 1.1 Specification* (see 9.4.5: Get\_Status), all requests are stalled except GET\_STATUS, CLEAR\_FEATURE, and SET\_FEATURE requests.)

<sup>(4)</sup> Requests are handled with respect to USB 1.1 when specified as such, but many device reactions are not specified by USB 1.1.)

<sup>(5)</sup> During a SET\_ADDRESS autodecoded command, only the seven LSBs are significant for the new address (decimal value from 0 to 127); all others are discarded.

**Table 29-55. Autodecoded Versus Non-Autodecoded Control Requests <sup>(1) (2) (3) (4)</sup> (continued)**

| Request               | Recipient | Status          | CPU Required Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Device Behavior if Device Is Not Configured |
|-----------------------|-----------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| GET_DESCRIPTOR        | All       | Non-autodecoded | The CPU must write descriptor data into endpoint 0 FIFO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Command is passed to the CPU.               |
| SET_DESCRIPTOR        | All       | Non-autodecoded | The CPU must stall the command (via SYSCON2.STALL_CMD bit) if it does not support set descriptor requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Command is passed to the CPU.               |
| GET/SET CONFIGURATION | Device    | Non-autodecoded | The CPU must stall the command (via SYSCON2.STALL_CMD bit) if configuration number is not correct. If the request is SET_CONFIG, the CPU must reset all endpoints, halt endpoints not used by the default interface setting, set SYSCON1.SELF_PWR value if device is self-powered for the configuration set, and then set SYSCON2.DEV_CFG bit (if config nb is not 0), or set SYSCON2.CLR_CFG bit (if config nb is 0) before allowing status stage to complete. The device moves to configured state (if DEV_CFG set), or moves to addressed state (if CLR_CFG set) and a DS_CHG interrupt is asserted to the CPU. | Command is passed to the CPU.               |
| GET/SET INTERFACE     | Interface | Non-autodecoded | The CPU must stall the command (via SYSCON2.STALL_CMD bit) if interface/setting number is not correct. If the request is SET_INTERFACE, the CPU must reset endpoints used by the interface and halt endpoints not used by the interface setting before allowing status stage to complete.                                                                                                                                                                                                                                                                                                                          | Command is passed to the CPU.               |
| SYNCH_FRAME           | Endpoint  | Non-autodecoded | The CPU must stall the command if it does not support SYNCH_FRAME request, else write requested data in the endpoint 0 FIFO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Command is passed to the CPU.               |

#### 29.3.7.6 Note on Control Transfers Data Stage Length

The control transfer data stage length is indicated in the setup data packet.

During control reads, if the USB host requests more data than indicated in the setup packet, unexpected IN transaction is STALLED, causing STALL handshake for all remaining transactions of the transfer until next SETUP. If the USB host requires less data than indicated in the setup packet, the transfer is not STALLED. However, if the host moves to status stage earlier than expected for a non-autodecoded request, the OUT status stage is NAKed because the CPU has not enabled the RX FIFO.

During control writes, if the USB host sends more bytes than indicated in the setup packet, the transfer is STALLED. If the USB host sends fewer bytes than were expected, the request is accepted. But if the USB host moves to status stage earlier than expected for a non-autodecoded request, the IN status stage is NAKed because the CPU has not enabled the TX FIFO.

### 29.3.8 USB Device Initialization

To allow communication between the device and a USB host, the CPU must configure the device by filling the configuration registers.

For each endpoint, the CPU must write on the dedicated register:

- Endpoint size
- Whether double-buffering is allowed for endpoint or not
- Endpoint type (ISO or non-ISO)
- Address of the pointer

System software must choose how to allocate the 2040 available bytes of USB device controller RAM to the USB endpoints. Receive endpoint size and type are configured using the EP1\_RX through EP15\_RX registers. Transmit endpoint size and type are configured using the EP1\_TX through EP15\_TX registers. Figure 29-57 shows an example of the RAM organization, obtained by following the flowchart shown in Figure 29-58.

**Figure 29-57. Example of RAM Organization**

Once the endpoints are configured, the CPU must set the `SYSCON1.CFG_LOCK` bit. If this bit is not set, all transactions are ignored by the core. Then, when the CPU is ready to communicate with the USB host, it must set the `SYSCON1.PULLUP_EN` bit. The CPU can wait until the `DS_CHG` attach interrupt has been detected and handled before setting the `SYSCON1.PULLUP_EN` bit. The USB host cannot detect the device until this bit is set.

Figure 29-58 and Figure 29-59 show flowcharts for the configuration phase.

**Figure 29-58. Device Configuration Routine**

**Figure 29-59. Endpoint Configuration Routine**

### 29.3.9 Preparing for Transfers

To avoid NAK handshakes for the first transaction on an endpoint, the CPU must prepare the endpoint FIFO for receiving or transferring data. After the first transaction, the FIFO is enabled during the interrupt handling (ISR flowchart).

For receive endpoints, this phase consists of enabling the FIFO to receive data from the USB host. If double buffering is allowed for the endpoint, setting the CTRL.SET\_FIFO\_EN bit enables both FIFOs. Therefore, it is not possible to allow a single transaction when double buffering is used.

The CPU enters the prepare for USB RX transfers routine, presented once after the enumeration phase, and then properly reacts to EP interrupts. Whether double-buffering is allowed or not is transparent to the CPU, unless both FIFOs are cleared through a CTRL.CLR\_EP or CTRL.RESET\_EP. In that case, and in the case where the CPU finishes to handle an interrupt without having set the CTRL.SET\_FIFO\_EN bit, the CPU must reenter the prepare for USB RX transfers routine.

For transmit endpoints, the CPU enters the prepare for endpoint n TX transfer routine, presented each time a new file must be transmitted from endpoint n to USB host. The CPU must not enter this routine until data written into TX FIFO from the previous transfer have all been received successfully by the USB host (ACK interrupt received), unless TX FIFO is cleared through the CTRL.CLR\_EP or CTRL.RESET\_EP bits (see Figure 29-60 and Figure 29-61).

**NOTE:** This does not apply to endpoint 0, which is not used before a setup interrupt occurs. At setup interrupt, the CPU reacts appropriately, and enables EP0 FIFO only if necessary.

To ensure proper usage of the module, you cannot prepare data on different endpoints at the same time. You can enter a routine once the routine is not being used by another endpoint (no parallelism); the EP\_NUM register can be accessed via different routines.

**Figure 29-60. Prepare for USB RX Transfers Routine**

**Figure 29-61. Prepare for TX Transfer on Endpoint n Routine**

### 29.3.10 USB Device Interrupt Service Routine (ISR) Flowcharts

The flowcharts in this section give general operational guidelines for USB device ISR processing. System-architecture-specific details are left to the engineers who write the CPU and USB host code. One USB-specific interrupt register is provided (IRQ\_SRC), including:

- General USB interrupts (including endpoint 0, DMA and device states interrupts) on Vectored Interrupt Manager (VIM) channel # 69 (by default)
- Non-ISO endpoint-specific interrupt on VIM channel # 70 (by default)
- Start of frame (SOF) interrupt for ISO transactions on VIM channel # 68 (by default)

The general USB interrupt ISR must handle non-autodecoded control transfers on endpoint 0 and some specialty interrupts generated because of USB device state modifications or DMA transfers. The ISR for the endpoint-specific interrupt must handle interrupts from the USB module that are generated because of USB activity for non-isochronous endpoints. The SOF ISR is responsible for handling isochronous endpoints and, if needed by the application, tracking the USB frame number. Many flowcharts are presented in this chapter to provide guidelines for how to handle the interrupts related to the USB device controller module. The flowcharts in this part suppose that the SYSCON1.NAK\_EN bit is cleared.

---

**NOTE:** A key assumption behind the flowcharts presented here is that the application provides separate buffers for each direction of endpoint, except for endpoint 0. The flowcharts read from these application buffers for IN transactions on TX endpoints and write to these application buffers for OUT transactions on RX endpoints.

The USB device controller does not support reentrant interrupts. Each USB device controller must be handled completely before handling another USB device controller interrupt. This restriction occurs because there is only one EP\_NUM register, so endpoint control operations must be completed before working with another endpoint or endpoint direction.

---

### 29.3.11 Important Note on USB Device Interrupts

When an endpoint interrupt is asserted, the CPU writes the EP\_NUM register with the EP\_NUM.EP\_SEL bit set to 1. The CPU must finish the interrupt handling before clearing the EP\_NUM.EP\_SEL bit, because clearing this bit clears the corresponding status bit in the STAT\_FLG register (ACK, NAK, STALL). When an interrupt is pending on an endpoint, the CPU must not select and then unselect the endpoint without handling the interrupt, because this clears the pending transaction status flags. The CPU does not need to set EP\_NUM.EP\_SEL to 1 when setting CTRL.SET\_FIFO\_EN, CTRL.SET\_HALT, and CTRL.CLR\_HALT bits.

The endpoint status (STAT\_FLG register) is updated at the end of each USB transaction if the previous transaction has been handled. If a pending interrupt has not been handled when a new non-transparent transaction occurs, status flags are not updated (and NAK is returned, even if FIFO was enabled, or STALLED if the EP halt feature was set), so that the CPU never misses an ACKed transaction. If double-buffering is used for an endpoint, STAT\_FLG is updated if there is zero or one interrupt pending for the endpoint, and is not updated if there are already two interrupts pending on the endpoint.

The CPU does not need to set the SYSCON1.NAK\_EN bit during normal operation. However, for debugging process, this bit can be set when the CPU finishes handling an EP interrupt without having set the corresponding CTRL.SET\_FIFO\_EN bit. During TX transaction, if the SYSCON1.NAK\_EN bit is set, the CPU must wait for a NAK interrupt to write the TX data, to avoid a possible conflict caused by the NAK interrupt received while the CPU was writing the TX data.

### 29.3.12 Parsing General USB Device Interrupt

The general USB interrupt (VIM channel # 69 by default) ISR must parse the interrupt identifier register IRQ\_SRC to determine the types of general USB interrupts that are active. These include interrupts relating to USB device state modifications (USB reset, suspend/resume, during enumeration phase) and control transfers on endpoint 0 or non-ISO DMA transfers in either receive or transmit mode. Multiple interrupts can be active at any time, and all must be dealt with by the ISR before returning from the ISR. [Figure 29-62](#) shows an appropriate flowchart for parsing the general USB interrupts.

**Figure 29-62. General USB Interrupt ISR Source Parsing Flowchart**

### 29.3.13 Setup Interrupt Handler

A separate interrupt flag exists for setup transactions so that the CPU cannot miss a setup transaction, even if it occurs during the data or status phase of another transfer (case of an aborted transfer). The setup parsing function captures the control transfer request information for use in determining which USB bus activity is needed and in controlling how the CPU must generate or respond to the control transfer. This information includes the following:

- bmRequestType
- bmRequest

- wValue
- wIndex
- wLength

The setup interrupt handler shown in [Figure 29-63](#) is responsible for processing setup transactions occurring on endpoint 0. It calls the routine that parses the control transfer request information, shown in [Figure 29-64](#) to set flags that the rest of the ISR code can use to control proper response to control transfers. Two flags are set by the setup interrupt handler, to be used during endpoint 0 interrupt handlers:

- Control read flag
- Control write flag

**Figure 29-63. Setup Interrupt Handler**

**Figure 29-64. Parse Command Routine (Setup Stage Control Transfer Request)**

### 29.3.14 Endpoint 0 RX Interrupt Handler

Figure 29-65 shows the endpoint 0 RX portion of the general USB interrupt handler, which must handle general USB interrupts related to control OUT transactions on endpoint 0. No EP0 interrupt is generated for autodecoded control transfers.

**Figure 29-65. Endpoint 0 RX Interrupt Handler**

**Figure 29-66. Prepare for Control Write Status Stage Routine**

To support the SET\_DESCRIPTOR command, when in commspecific actions, you must first reset all endpoints by selecting the endpoint and then clear it, unlock the configuration, change the new one, lock the configuration, go in prepare for transfers, and enable all interrupts (see [Figure 29-66](#)).

### 29.3.15 Endpoint 0 TX Interrupt Handler

[Figure 29-67](#) shows the TX portion of the general USB interrupt handler, which must handle general USB interrupts related to control IN transactions on endpoint 0.

The endpoint 0 TX interrupt handler must be able to move data into the endpoint 0 TX FIFO when the application buffer for endpoint 0 TX data is not empty and an endpoint 0 TX interrupt occurs signaling an ACKed non-autodecoded endpoint 0 IN transaction. This data can be control read data stage information or control write status stage handshaking information (see [Figure 29-68](#)).

Figure 29-67. Endpoint 0 TX Interrupt Handler

**Figure 29-68. Prepare for Control Read Status Stage Routine**

### 29.3.16 Device States Changed Handler

This section describes how USB device states and transitions states are decoded by the USB device controller and how they can be handled.

The state machine (see [Figure 29-69](#)) shows how the USB device controller device moves from one state to another state with respect to the USB1.1 specification. Attach/unattach transition is not shown in the transition flow.

Because SET\_CONFIGURATION is not decoded by the core, the CPU has the responsibility to distinguish a SET\_CONFIGURATION with a nonvalid configuration value from other SET\_CONFIGURATION requests and to set SYSCON2.DEV\_CFG only if the configuration value is valid (value 0 is nonvalid), when the device is in addressed state. When the device is in configured state, the CPU has the responsibility to set SYSCON2.CLR\_CFG if the configuration number is 0 so that the device moves to addressed state.

Device states are visible in the DEVSTAT register and are decoded as follows.

- Attached: The device is attached to the USB and powered.
- Default: The device is attached to the USB, is powered, and has been reset.
- Addressed: The device is attached to the USB, is powered, has been reset, and an address has been assigned. The device moves into the addressed state after a SET\_ADDRESS request with an address number other than 0.
- Configured: The device is attached to the USB, is powered, has been reset, has an address other than 0, and is configured. The device moves into the configured state after a valid SET\_CONFIGURATION request, only if the CPU has set the SYSCON2.DEV\_CFG bit (meaning the configuration is valid).
- Suspended: The device is at minimum default and has not seen bus activity for 5 ms.
- Reset: When set, the device is receiving a valid USB host reset.
- R\_WK\_OK: This bit is set (cleared) automatically after a valid SET\_DEVICE\_FEATURE (CLEAR\_DEVICE\_FEATURE) request from the USB host.

Any change in the DEVSTAT register bits triggers a device change interrupt (IRQ\_SRC.DS\_CHG), if enabled.

The device moves to addressed state after the status stage of a valid SET\_ADDRESS, even if the status stage ACK handshake is received corrupted or not sent by the USB host. A SET\_DEVICE\_FEATURE or a CLEAR\_DEVICE\_FEATURE is effective after setup transaction, even if no status stage occurs. A SET\_CONFIGURATION request is effective before status stage, when the CPU sets the SYSCON2.CLR\_CFG or SYSCON2.DEV\_CFG bit (see [Figure 29-70](#)).

**Figure 29-69. USB Device Controller Device State Transitions**

- A USB reset generates two interrupts (when USB reset is asserted and then when USB reset completes.)
- B No interrupt is asserted by the core for transitions shown with dashed lines.

Figure 29-70. Typical Operation for USB Device State Changed Interrupt Handler

### 29.3.17 Device States Attached/Unattached Handler

Device attached/unattached interrupts occur when the device detects that its VBUS has changed. System software can disable the USB device controller clock after IRQ\_SRC.DS\_CHG is cleared after servicing an unattached interrupt. Disabling the USB device controller clock before IRQ\_SRC.DS\_CHG is cleared can result in improper functionality for future USB device controller interrupts (see [Figure 29-71](#)).

**Figure 29-71. Attached/Unattached Handler**

### 29.3.18 Device State Configuration Changed Handler

When a configuration changed interrupt occurs, the USB device has received a set configuration operation. When this occurs, the configuration-changed handler performs the operations shown in Figure 29-72.

**Figure 29-72. Configuration Changed Handler**

### 29.3.19 Device State Address Changed Handler

When a address changed interrupt occurs, the USB device has received a set address operation. When this occurs, the address-changed handler performs the operations shown in [Figure 29-73](#).

**Figure 29-73. Address Changed Handler**

### 29.3.20 USB Device Reset Interrupt Handler

When a USB reset occurs, the USB module generates a general USB interrupt to the CPU (see [Figure 29-74](#)). The CPU responds to this interrupt by performing the following operations:

- Cancels any ongoing USB transaction and/or control transfer handling
- Clears any copies that the application has of configuration number or alternate interface numbers
- Clears any application-specific information relating to halted endpoints
- Clears any application-specific information relating to the remote wake enable flag
- Clears any application-specific information relating to the suspend mode flag
- Clears any application-specific copy of the frame number

Figure 29-74. USB Device Reset Handler Flowchart

### 29.3.21 Suspend/Resume Interrupt Handler

When a USB device suspend/resume general USB interrupt occurs, the USB module has either entered or left suspend mode. The CPU code must determine which and react appropriately (see [Figure 29-75](#)).

The suspend sense hardware is implemented to trigger only after 5 ms of bus idle. This forces compliance with the *USB Specification Version 1.1*  $T_{WTRSM}$  timing parameter (3 ms of IDLE to identify suspend, 2 ms before the remote device can signal resume).

If the CPU wants to wake the device from suspend mode and remote wake-up enable is set ( $DEVSTAT.R\_WK\_OK = 1$ ), it must first turn its clock on (if stopped), and then set  $SYSCON2.RMT\_WKP$ . The device then drives resume.

If shutoff is enabled (SYSCON1.SOFF\_DIS=0), the 48-MHz clock is automatically shut off at suspend and turned on at resume (USB host or CPU driven). Setting or not setting the SYSCON1.SOFF\_DIS bit is part of the device configuration. However, the CPU can modify its value at suspend interrupt time if necessary.

A USB reset is also a valid way to exit suspend mode. But the suspend/resume handler and the USB reset handler do not have to take this into account, because three interrupts are generated in that case (one for resume, one for reset, and one for end of reset).

**Figure 29-75. Typical Operation for USB Suspend/Resume General USB Interrupt Handler**

### 29.3.22 Parsing Non-ISO Endpoint-Specific Interrupt

The endpoint-specific interrupt ISR (also known as the non-isochronous interrupt, on VIM channel # 70 by default) must parse the interrupt identifier register IRQ\_SRC to determine the interrupts that are active (IRQ\_SRC.EPN\_RX, IRQ\_SRC.EPN\_TX, or both). Two interrupts can be active at any time. The ISR must then read the EPN\_STAT register to determine the endpoint causing the interrupt. For each direction, only one endpoint interrupt can be active at a time (see [Figure 29-76](#)).

**Figure 29-76. Non-ISO Endpoint-Specific (Except EP 0) ISR Flowchart**

### 29.3.23 Non-ISO, Non-Control OUT Endpoint Receive Interrupt Handler

Figure 29-77 shows the operations necessary to handle non-ISO, non-control OUT endpoint-specific receive interrupts. This flowchart shows two different RX transaction handshaking interrupts. There is a third interrupt handshaking possibility when NAK interrupts are enabled, which is not depicted here. Depending on the application-specific actions needed for various endpoints in the real system, it is possible to use one routine that is common to all of the non-ISO, non-control receive endpoints, where the only differences are in the EP\_NUM register value set and the selection of the proper application RX data buffer in the read non-ISO RX FIFO data routine (see Figure 29-78).

This flowchart does not attempt to document control endpoint 0 receive interrupts, which are discussed separately because of the more complex three-stage transfer mechanism used for control writes.

**Figure 29-77. Non-Isochronous Non-Control Endpoint Receive Interrupt Handler**

**Figure 29-78. Read Non-Isochronous RX FIFO Data Flowchart**

### 29.3.24 Non-ISO, Non-Control IN Endpoint Transmit Interrupt Handler

Figure 29-79 shows the operations necessary to handle non-ISO, non-control IN endpoint-specific transmit interrupts. This flowchart shows two TX transaction handshaking interrupts. There is a third interrupt handshaking possibility when NAK interrupts are enabled, which is not depicted here. Depending on the application-specific actions needed for various endpoints in the real system, it is possible to use one routine that is common to all of the non-ISO, non-control transmit endpoints, where the only differences are in the EP\_NUM register value set and in the routine selection of the application TX buffer (see Figure 29-80).

This flowchart does not attempt to document control endpoint 0 transmit interrupts, which are discussed separately because of the more complex three-stage transfer mechanism used for control reads.

**Figure 29-79. Non-Isochronous Non-Control Endpoint Transmit Interrupt Handler**

Figure 29-80. Write Non-Isochronous TX FIFO Data Flowchart

### 29.3.25 SOF Interrupt Handler

SOF interrupts to the CPU (also known as isochronous interrupts on VIM channel # 68 by default) occur once per USB frame. The CPU must handle data traffic for the isochronous endpoints at each SOF interrupt. In addition, the SOF ISR can handle any application-specific activity related to the implicit timing of the SOF interrupt. [Figure 29-81](#) shows the SOF ISR flowchart. The read ISO RX FIFO data and write ISO TX FIFO data procedures are shown in [Figure 29-82](#) and [Figure 29-83](#), respectively.

**Figure 29-81. SOF Interrupt Handler Flowchart**

Figure 29-82. Read Isochronous RX FIFO Data Flowchart

**Figure 29-83. Write Isochronous TX FIFO Data Flowchart**

## 29.3.26 Summary of USB Device Controller Interrupts

Table 29-56 lists the interrupt types by endpoint types.

**Table 29-56. USB Device Controller Interrupt Type by Endpoint Type**

| Interrupt Type                 | General USB IRQs (VIM channel # 69 by default) |                   |                  |       | EP-Specific IRQs (Non-ISO Interrupt on VIM channel # 70 by default) |                     | SOF ISO Interrupt on VIM channel # 68 by default) |
|--------------------------------|------------------------------------------------|-------------------|------------------|-------|---------------------------------------------------------------------|---------------------|---------------------------------------------------|
|                                | Setup (EP0)                                    | Control (EP0) Out | Control (EP0) In | Other | Bulk or InterruptOut                                                | Bulk or InterruptIn | (Isochronous) SOF                                 |
| Transaction ACKed              |                                                | X                 | X                |       | X                                                                   | X                   |                                                   |
| Transaction NAKed (if enabled) |                                                | X                 | X                |       | X                                                                   | X                   |                                                   |
| Transaction Stalled            |                                                | X                 | X                |       | X                                                                   | X                   |                                                   |
| Setup                          | X                                              |                   |                  |       |                                                                     |                     |                                                   |
| SOF                            |                                                |                   |                  |       |                                                                     |                     | X                                                 |
| Device state changed           |                                                |                   |                  | X     |                                                                     |                     |                                                   |

### 29.3.26.1 USB Device Controller Clock Control

The device global clock module (GCM) provides a single 48-MHz clock to the USB device controller and USB host controller. This is the VCLKA3 clock domain. This clock domain can be stopped by software to reduce USB host and USB device controller power consumption when USB functionality is not needed. The GCM controls the 48-MHz clock to the USB device controller via the following memory-mapped registers:

- SYS.CDDIS
- SYS.CDDISSET
- SYS.CDDISCLR

### 29.3.26.2 USB Device Controller Hardware Reset

Reset of the USB device controller is provided by the SYS module. The system reset signal is used to reset the USB host controller and the USB device controller. When held in reset, the USB device controller does not recognize any USB activity, and its registers have no effect on USB functionality.

### 29.3.27 DMA Operation

The USB device controller provides support for six DMA channels. Three receive DMA channels are reserved to OUT transfers (ISO or non-ISO) and three transmit DMA channels are reserved to IN transfers (ISO or non-ISO). It is not possible to operate DMA transactions on control EP0.

**NOTE:** The CPU must not access an endpoint used in a DMA transfer through the EP\_NUM, CTRL, and STAT\_FLG registers (in DMA, this remark applies after the CPU has set the CTRL.SET\_FIFO\_EN bit to enable the RX DMA transfer). In particular, the CPU must not set the halt feature while the endpoint is selected in the RXDMA\_CFG register.

To use the DMA channels properly, you must set the DMA configuration during the address state interrupt (DS\_CHANGE).

The parameters used for DMA transactions (FIFO size, ISO endpoint, double-buffering, and pointers) are those defined for the associated endpoint.

#### 29.3.27.1 Receive DMA Channels Overview

Receive DMA channels are programmed via the three RXDMA control registers. Each channel is assigned to a given endpoint number by assigning a non-zero value in RXDMA\_CFG.RXDMA<sub>n</sub>\_EP fields (a 0 value means the DMA channel is deselected). Received OUT data must be read when an RX DMA request is active, through the register DATA\_DMA. The RX FIFO accessed is that of the endpoint for which the DMA request is active (only one RX DMA request is active at a time).

The USB device controller receive DMA channels 0, 1, and 2 are connected to the device System DMA controller requests # 15, 19, and 29, respectively.

#### 29.3.27.2 Non-Isochronous OUT (USB HOST -> CPU) DMA Transactions

During non-ISO transfers to a DMA operated OUT endpoint, a request to the CPU DMA controller is generated when data have been placed into endpoint FIFO and must be read. ACK and NAK interrupts are always disabled automatically by the core for DMA operated endpoints.

There are two dedicated maskable interrupts per DMA channel to control non-ISO OUT transfers.

#### 29.3.27.3 End of Transfer Interrupt (IRQ\_SRC.RX<sub>n</sub>\_EOT)

This interrupt signals that the core has detected an end-of-transfer (EOT). EOT occurs in the two following cases:

- When the last valid transaction to the endpoint is either an empty packet (ACK and buffer empty) or a packet whose size is less than the physical endpoint buffer size (ACK and buffer not full)
- When the number of received transactions has reached the programmed value in the RXDMA<sub>n</sub>.RX<sub>n</sub>\_TC field, if the RXDMA<sub>n</sub>.RX<sub>n</sub>\_STOP bit has been set by the CPU

After an end of transfer interrupt, the CPU must set CTRL.SET\_FIFO\_EN for the endpoint to reenale the channel.

The CPU must not initiate a new RX DMA transfer until it receives an end-of-transfer interrupt.

#### 29.3.27.4 Transaction Count Interrupt (IRQ\_SRC.RX<sub>n</sub>\_CNT)

The intent of this interrupt is watermark control. It can be used by the CPU to monitor the file size of incoming transfers and take appropriate actions if, for instance, the file being received exceeds an expected size.

A transaction count interrupt does not disable the ongoing DMA transfer.

A transaction count interrupt occurs each time the number of received transactions (and not bytes) has reached the programmed value in the receive transaction counter for the DMA channel. One transaction has a size equal to the buffer size of the selected non-ISO endpoint. RX<sub>n</sub>\_COUNT interrupt is asserted even if RXDMA<sub>n</sub>.RX<sub>n</sub>\_STOP has been set; in that case, both RX<sub>n</sub>\_COUNT and RX<sub>n</sub>\_EOT interrupts are asserted (see [Figure 29-84](#) through [Figure 29-87](#)).

The transaction count watermark is programmed in the RXDMA<sub>n</sub> register.

**Figure 29-84. Non-ISO RX DMA Transaction Example (RX\_TC=2)**

**Figure 29-85. Non-ISO RX DMA Start Routine**

**Figure 29-86. Non-ISO RX DMA EOT Interrupt Handler**

**Figure 29-87. Non-ISO RX DMA Transactions Count Interrupt Handler**

### 29.3.27.5 Isochronous OUT (USB HOST -> CPU) DMA Transactions

During ISO transfers to a DMA operated OUT endpoint, a request to the CPU DMA controller is generated every 1-ms frame when an isochronous data packet is received with no error. There is no interrupt associated with DMA transfer to ISO OUT endpoints (see [Figure 29-88](#) and [Figure 29-89](#)).

**Figure 29-88. ISO RX DMA Transaction**

**Figure 29-89. ISO RX DMA Start Routine**

### 29.3.27.6 Transmit DMA Channels Overview

Transmit DMA channels are programmed via the three TXDMA control registers. Each channel can be assigned to a given endpoint number by assigning a non-zero value in TXDMA\_CFG.TXDMA<sub>n</sub>\_EP (a 0 value means the DMA channel is deselected). The other three control registers (TXDMA0, TXDMA1, and TXDMA2) operate in a different manner for ISO and non-ISO endpoints. Transmitted data must be written into the DATA\_DMA when a TX DMA request is active. They are written into the TX FIFO of the endpoint associated with active request (only one TX DMA request active at a given time).

The USB device controller transmit DMA channels 0, 1, and 2 are connected to the device system DMA controller requests # 14, 20, and 28, respectively.

### 29.3.27.7 Non-Isochronous IN (CPU -> USB HOST) DMA Transactions

Non-ISO (bulk) TX DMA file transfers are virtually unlimited in size. The flowcharts depicted in [Figure 29-90](#) and [Figure 29-91](#) show how to handle small, medium, or large file transfers.

TXDMA0, TXDMA1, and TXDMA2 registers operate for non-ISO endpoints in the following manner. The transfer size counter (TXDMA<sub>n</sub>.TXN\_TSC) corresponds to either the number of bytes to transmit (EOT bit set) or the number of buffers to transmit (EOT bit cleared). The buffer size corresponds to the programmed size of the TX endpoint.

A request to the CPU main DMA controller is generated when the endpoint buffer is empty initially after that the START bit is set and then each time there is space free in TX FIFO for other TX packet to be written, until TXDMA<sub>n</sub>.TXn\_TSC counts down to zero. The request is removed when the buffer is full or when there are no more bytes of data to be sent.

A DMA transmit transfer done interrupt is signaled to the CPU after the last IN transaction completes successfully. This is after START bit was set and after TXDMA<sub>n</sub>.TXn\_TSC equals 0 for the selected DMA channel.

The CPU must not initiate a new TX DMA transfer until it receives a TX\_DONE interrupt.

A small file transfer less than 1024 bytes can be achieved in a single pass DMA signaled by a single interrupt completion. A file size equal to or greater than 1024 bytes needs two or more DMA passes, signaled by an interrupt completion after each pass.

[Figure 29-90](#) shows the necessary steps to prepare and permit a TX DMA transfer of any size. It also effectively starts the initial DMA transfer. The completion of this DMA task is signaled to the CPU via a DONE interrupt, whose handler is shown in [Figure 29-91](#). The start routine and the associated interrupt handler are tightly coupled.

**Figure 29-90. Non-ISO TX DMA Start Routine**

**Figure 29-91. Non-ISO TX DMA Done Interrupt Handler**

**Example 29-1. 100603 Bytes to Transfer via 32 Bytes IN Bulk Endpoint**

This gives XSWL=0x3, FBT=0x47, EOTB=0x1b,

which means five passes of DMA transfer, signaled by 5 TXn\_DONE interrupts, are required:

1. EOT=0, FBT=0, loop=3 32768 bytes transferred (1024 x 32 bytes)
2. EOT=0, FBT=0, loop=2 32768 bytes
3. EOT=0, FBT=0, loop=1 32768 bytes
4. EOT=0, FBT=0x47, loop=0 2272 bytes (71 x 32 bytes)
5. EOT=1, FBT=0x1B, loop=0 27 bytes

### 29.3.27.8 Isochronous IN (USB HOST -> CPU) DMA Transactions

For ISO endpoints, the transfer size counter (TXDMA<sub>n</sub>.TX<sub>n</sub>\_TSC) corresponds to the number of bytes to transmit. The programmed size must not exceed the programmed buffer size of the endpoint. Otherwise, the result is unpredictable (see [Figure 29-92](#)).

A request to the CPU main DMA controller is generated when the endpoint buffer is empty initially after the START bit is set, and then after each SOF (every 1 ms). The request is removed when the number of bytes written in the buffer matches the TXDMA<sub>n</sub>.TX<sub>n</sub>\_TSC value.

During ISO transfers to a DMA operated IN endpoint, a request to the CPU system DMA controller is generated every 1-ms frame when an isochronous data packet is received with no error. There is no special interrupt associated with the DMA transfer.

No interrupt is signaled to the CPU during DMA operation to ISO IN endpoints.

**Figure 29-92. ISO TX DMA Start Routine**

### 29.3.27.9 Important Note on DMA Requests

For each direction, only one DMA request can be active at any time. A request must then be serviced to allow the next pending request on the same direction to be asserted. In particular, a TX DMA request is asserted at each start-of-frame if a TX DMA channel is configured for an isochronous endpoint; this request must be serviced imperatively.

### 29.3.27.10 Note on DMA Channels Deconfiguration

It is recommended that the CPU wait for an EOT (RX) or a DONE (TX) interrupt before disabling the channel by writing a value 0 in the TX/RXDMA\_CFG register. However, if needed by the application, the CPU can unselect the endpoint number in the TX/RXDMA\_CFG register during a DMA transfer. The resulting behavior is:

- For RX transfer:
  - If RX DMA request is active for the endpoint when the endpoint is unselected, deconfiguration is effective only at the end of the RX DMA request (that is, after all the DMA data have been read). When double-buffering is used, the deconfiguration is effective after both buffers have been read (if both buffers were not empty at unselection). An EOT interrupt is asserted if an end-of-transfer is detected.
  - If the RX DMA request is not active when unselection occurs, the effect is immediate.
- For TX transfer:
  - If the request is active when the endpoint is unselected, deconfiguration is effective after the TX DMA request has been handled and the TX data have been sent through an IN transaction (both buffers in case of double-buffering with both buffers full). No TX\_DONE interrupt is asserted even if TXDMA<sub>n</sub>.TSC bit value is 0 after the transaction.
  - If the TX DMA request is inactive when the endpoint is unselected, deconfiguration is effective when all data available in TX buffer(s) have been sent through IN transaction(s). If the TXDMA<sub>n</sub>.TSC value is 0 at this point, no TX\_DONE interrupt is asserted. If TX\_DONE interrupt had already been asserted when the endpoint is deselected, configuration is effective only after the TX\_DONE interrupt handling.

TX/RXDMA\_CFG.TX/RXDMA<sub>n</sub>\_EP reflects the endpoint value until deconfiguration is effective. The CPU must read this register to know if the channel has been disabled yet or not. It must wait until the read value is 0 before performing other actions to the endpoint. After effective deconfiguration, all transactions to the endpoint generate an endpoint-specific interrupt (if non-transparent).

If the selected endpoint is of isochronous type, deconfiguration is effective after the TX/RX request has been serviced, and the subsequent isochronous transactions are handled at SOF interrupt through the endpoint registers (EP\_NUM and STAT\_FLG).

## 29.3.28 Power Management

Figure 29-93 shows the values assigned to the USB device controller signals concerned with power management, in the function of the device state. These signals are:

- PUEN\_O: Pullup enable signal, always reflecting the SYSCON1.PULLUP\_EN register bit
- SHUTOFF\_O: Power circuitry shutoff signal, controlled by the core and the SYSCON1.SOFF\_DIS bit
- DS\_WAKE\_REQ\_ON: Deep-sleep wake request, asserted low when the interface clock is needed
- SUSPEND\_O: Suspend signal, asserted high when the device is in suspend mode

From a software point of view, Figure 29-94 shows the reaction. This flowchart does not need to be implemented; it only reflects the way the module can enter deep sleep.

**Figure 29-93. Power Management Signal Values**

A SHUTOFF\_O value is 0 is the LH has set SYSCON1.SOFF\_D bit.

**Figure 29-94. Power Management Flowchart**

## 29.4 USB Connectivity

This section includes:

- Transceiver interface
- Selecting and configuring USB connectivity
- Transceiver signaling
- Host controller connectivity with USB transceivers
- USB function controller connectivity with USB transceivers
- USB hardware considerations

### 29.4.1 Transceiver Interface

The device provides three USB ports, two of which may be used simultaneously. In a USB system, a USB transceiver is needed for each USB port. It converts between signaling appropriate for the USB controllers and signaling appropriate for the USB cable. This device does not provide an integrated USB transceiver.

Several different types of external transceiver signaling are supported. Signaling between the USB controller and the external USB transceiver for monitoring and controlling the differential USB signal is done via a 6-wire signaling interface, with two or more additional control signals provided either by additional signals or via an I2C link.

### 29.4.2 Selecting and Configuring USB Connectivity

The process of selecting desired USB connectivity and configuring the device for that connectivity can be done using the steps listed below.

#### 29.4.2.1 Choose the Desired USB Functionality

Choose the desired USB functionality. The USB module on this microcontroller supports the following configurations:

- 1 USB Host Port + 1 USB Device Port, OR
- 2 USB Host Ports

Interface signals for the USB host port #2 are multiplexed with interface signals for the USB device port. If the application requires the use of the USB device port, then the USB host port #2 must first be powered down.

#### 29.4.2.2 Select How USB Functionality Is Multiplexed to Pins

Refer to [Table 29-1](#) for information on multiplexing and control of USB host ports and USB device port interface signals at the top level.

### 29.4.3 Transceiver Signaling

The USB module on this device uses a unidirectional (6-wire) signaling type for the transceiver. The signaling is shown in [Table 29-57](#).

**Table 29-57. Signaling Between USB Controller and Unidirectional USB Transceiver Using DAT/SE0 Signaling**

| Logical Signal Name(s) | Pin Direction | Transceiver Pin Direction | Description                                                                                                                                                                                                      |     |     |          |          |
|------------------------|---------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-----|----------|----------|
| GZO                    | Output        | Input                     | When low, USB transceiver drives D+ and D-.                                                                                                                                                                      |     |     |          |          |
| DAT and SE0            | Output        | Input                     | Controls the values output by the USB transceiver on D+ and D- when GZO is low. Ignored when GZO is high.                                                                                                        |     |     |          |          |
|                        |               |                           | GZO                                                                                                                                                                                                              | DAT | SE0 | D+       | D-       |
|                        |               |                           | 0                                                                                                                                                                                                                | 0   | 0   | 0        | 1        |
|                        |               |                           |                                                                                                                                                                                                                  | 1   | 0   | 1        | 0        |
|                        |               |                           |                                                                                                                                                                                                                  | X   | 1   | 0        | 0        |
|                        |               |                           | 1                                                                                                                                                                                                                | X   | X   | Undriven | Undriven |
| RCV                    | Input         | Output                    | Output from transceiver differential receiver.                                                                                                                                                                   |     |     |          |          |
|                        |               |                           | D+                                                                                                                                                                                                               |     | D-  |          | RCV      |
|                        |               |                           | 0                                                                                                                                                                                                                |     | 0   |          | X        |

This device does not support unidirectional transceivers that implement VPO/VMO signaling.

### 29.4.4 Host Controller Connectivity With USB Transceivers

To provide a robust USB solution, a system that provides a USB host controller must implement certain features. These features include a type-A receptacle, power on the VBUS signal (can be switched or unswitched power), transient suppression, pull-down resistors, and USB-compatible downstream port transceiver.

**Figure 29-95. Pin Group 0 USB Host Using 6-Wire USB Transceiver**

Proper initialization of the device to support this mode of operation requires proper setting of the top-level pin multiplexing (see [Section 29.4.2.2](#)).

### 29.4.5 USB Function Controller Connectivity With USB Transceivers

To provide a robust USB solution, a system that provides a USB device controller port must implement certain features. These features include:

- A USB type-B or mini-B receptacle
- VBUS power detection
- Transient suppression
- A controllable pullup resistor to the D+ or D- line
- USB-compatible upstream port transceiver

Optional weak pulldown resistors can be used to hold the D+ and D- signals at voltages below the USB transceiver VIL level when there is no USB host connected to the USB Type B connector. By keeping D+ and D- voltages below VIL, the USB transceiver IDDQ can be reduced. Choice of value for the pulldown resistors must be made carefully so that the circuit meets the requirements of the *USB Specification*.

The USB function controller only supports implementation as a full-speed USB device. As such, the pullup resistor must be connected to the D+ signal to indicate implementation of a full-speed USB device.

This device supports a 6-wire connection to the USB transceiver.

**Figure 29-96. USB Device Connections on USB Pin Group 0 Using 6-Wire Transceiver**

Proper initialization of the device to support this mode of operation requires proper setting of the top-level pin multiplexing (see [Section 29.4.2.2](#)).

## **29.4.6 USB Hardware Considerations**

### **29.4.6.1 VBUS Power Switching for USB Type A Host Receptacles**

The USB specification places several VBUS requirements on USB hosts, including current capability, droop, and other important characteristics. Circuits that meet the USB specification requirements can be implemented using Texas Instruments devices such as the TPS2552 and TPS2553 power distribution switch devices. Further information, including data sheets and application notes, can be found at the Texas Instruments web site.

### **29.4.6.2 Transient Suppression for USB Connectors**

It is important to provide transient suppression for USB connectors. Electrostatic discharge that occurs when a user connects or disconnects a USB cable can have a dramatic effect on a system if not suppressed. Texas Instruments offers several devices for transient suppression on USB connections, such as the SN65220, SN65240, and SN75240 universal serial bus port transient suppressor devices. Further information, including data sheets and application notes, can be found at the Texas Instruments web site.

### **29.4.6.3 VBUS Monitoring for USB Function Controller**

A USB function controller must be capable of monitoring the VBUS voltage provided by the upstream USB host controller. The device provides the input pin USB\_VBUS, which is provided to the USB function controller. This input is a CMOS input that is not rated for the full VBUS range defined by the USB specification. An external signal level shifter is required to convert the VBUS signal range to a range suitable for the USB\_VBUS pin.

### **29.4.6.4 USB D+ Pullup Enable for USB Function Controller**

The USB\_PUEN pin is driven high when the pullup is active and is driven low when the pullup is inactive. In this mode of operation, the pullup resistor can be connected directly between the USB\_PUEN and the D+ signal. Some transceivers such as the TUSB1105 from Texas Instruments have an additional input pin called SOFTCON. When this pin is driven High, the D+ gets pulled up through an external resistor to 3.3V. The USB\_PUEN can be connected to the SOFTCON pin in this case.

### **29.4.6.5 USB D+, D- Pulldown for USB Function Controller**

System implementations that use the USB function controller and are sensitive to supply current requirements can implement weak pulldown resistors on the USB D+ and D- signals associated with the USB Type-B receptacle. When there is no host controller attached upstream of the USB Type-B receptacle, the undriven D+ and D- wires can float to voltages that cause excessive current consumption by the USB transceiver. Weak pulldowns can help prevent this problem. Selection of pulldown resistors depends on transceiver characteristics, D+ pullup resistor implementation, and board layout, and must be designed to meet USB D+ and D- signal requirements.

## ***Data Modification Module (DMM)***

This chapter describes the functionality of the Data Modification Module (DMM), which provides the capability to modify data in the entire 4 GB address space of the device from an external peripheral, with minimal interruption of the application.

| Topic                              | Page        |
|------------------------------------|-------------|
| <b>30.1 Overview.....</b>          | <b>1660</b> |
| <b>30.2 Module Operation .....</b> | <b>1661</b> |
| <b>30.3 Control Registers.....</b> | <b>1666</b> |

## 30.1 Overview

### 30.1.1 Features

The DMM module has the following features:

- Acts as a bus master, thus enabling direct writes to the 4GB address space without CPU intervention
- Writes to memory locations specified in the received packet (leverages packets defined by trace mode of the RAM trace port (RTP) module)
- Writes received data to consecutive addresses, which are specified by the DMM module (leverages packets defined by direct data mode of RTP module)
- Configurable port width (1, 2, 4, 8, 16 pins)
- Up to 100 Mbit/s pin data rate
- Unused pins configurable as GIO pins

### 30.1.2 Block Diagram

Figure 30-1 shows the block diagram for the DMM.

## 30.2 Module Operation

The DMM receives data over the DMM pins from external systems and writes the received data directly to the base address programmed in the module plus offset address given in the packet or into a buffer specified by start address and length. It leverages the protocol defined by the RAM Trace Port (RTP) module to have a common interface definition for external systems. It can also be used to connect an RTP and DMM module together for fast processor intercommunication.

The DMM module provides two modes of operation:

- **Trace Mode:** In this mode, the DMM writes the received data directly to an address that is calculated from the base address programmed into the destination register ([Section 30.3.12](#); [Section 30.3.14](#)) plus the offset address contained in the received packet. An interrupt can be generated when data is written the lowest address of a programmed region. This capability enables the sender to raise an interrupt at the receiver while sending specific information.
- **Direct Data Mode:** In this mode, the DMM writes the received data into an address range of the 4GB address space. The buffer start address ([Section 30.3.8](#)) and blocksize ([Section 30.3.9](#)) is programmable in the DMM module. When the buffer reaches its end address, the buffer pointer wraps around and points to the beginning of the buffer again. The EO\_BUFF flag ([Section 30.3.5](#)) will be set and if enabled, an interrupt will be generated to indicate a buffer-full condition. Another interrupt, can be configured to indicate different buffer fill levels. This can be accomplished by programming a certain fill level into the DMMINTPT register ([Section 30.3.11](#)). The PROG\_BUFF flag ([Section 30.3.5](#)) indicates that this level has been reached.

Data will be captured by the input buffer and moved to the appropriate bit field in the deserializer. When the deserializer is completely full, the data will be moved to the output buffer register. A two-level buffer is implemented to avoid overflow conditions if the internal bus is occupied by other transactions. In addition the DMMENA signal can be used to signal the external hardware that an overflow might occur if more data is sent. The automatic generation of the DMMENA signal can be configured by setting the ENAFUNC bit ([Section 30.3.16](#)). While the DMMENA signal is active, the DMM module will not receive any new data.

The DMM is a bus master and forwards the received data to the bus system. The write operation will be minimally intrusive to the program flow, because the CPU/DMA access will only be blocked if the CPU/DMA accesses the same resource as the DMM.

To prevent an external system from overwriting critical data in the memory while configured in Trace Mode, a memory protection mechanism is implemented via a programmable start address and block size of a region. A maximum of four destinations with two regions each are supported.

For proper operation, at least DMMCLK, DMMSYNC and DMMDATA[0] need to be programmed in functional mode ([Section 30.3.16](#)). If a large amount of data should be transmitted in a short time, more data pins should be used in functional mode. The module supports 1, 2, 4, 8, or 16-pin configurations.

The module can be configured to handle a free running clock provided on DMMCLK ([Section 30.3.1](#)). Clock pulses between two DMMSYNC pulses that exceed the number of valid clock pulses for a packet will be ignored.

### 30.2.1 Data Format

Below is a description of the packet and frame format.

#### 30.2.1.1 Clocking Scheme

The DMM supports both continuous and noncontinuous clocking. The clock received on DMMCLK in the continuous clocking scheme is a free-running clock. In noncontinuous clocking scheme, the clock will stop after each packet and will start with the reception of a DMMSYNC signal.

#### 30.2.1.2 Trace Mode Packet

[Figure 30-2](#) illustrates the trace mode packet format. One packet consists of 2 bits (DEST) denoting the destination in which the data is stored, 2 status bits (STAT), the 2-bit SIZE of the data, the 18-bit address of where the data should be written to, and a variable data field.

The DEST bits (Table 30-1) will be used to determine which destination register applies to the transmitted data and the received address determines if the packet falls into a valid region of the destination area. If the address is valid, the base address, programmed in one of the destination registers (Section 30.3.12; Section 30.3.14) of this particular region will be applied to create the complete 32-bit address for the destination. The DMM module only takes action on a "11" setting of the STAT bits (Table 30-2). This signals that an overflow in the transmitting hardware module has occurred. If this is the case the SRC\_OVF flag (Section 30.3.5) will be set and the received data will be written to the address specified in the packet. The size information of the data transmitted in the packet is denoted in the SIZE bits (Table 30-3) of the packet. Depending on the SIZE information, the module expects to receive only this amount of data.

**Figure 30-2. Trace Mode Packet Format**

Table 30-1 through Table 30-3 illustrate the encoding of packet format in trace mode.

**Table 30-1. Encoding of Destination Bits in Trace Mode Packet Format**

| DEST[1:0] | Destination |
|-----------|-------------|
| 00        | Dest 0      |
| 01        | Dest 1      |
| 10        | Dest 2      |
| 11        | Dest 3      |

**Table 30-2. Encoding of Status Bits in Trace Mode Packet Format**

| STAT[1:0] | Status     |
|-----------|------------|
| 00        | don't care |
| 01        | don't care |
| 10        | don't care |
| 11        | overflow   |

**Table 30-3. Encoding of Write Size in Packet Format**

| SIZE[1:0] | Write Size |
|-----------|------------|
| 00        | 8 bit      |
| 01        | 16 bit     |
| 10        | 32 bit     |
| 11        | 64 bit     |

### 30.2.1.3 Direct Data Mode Packet

Figure 30-3 illustrates the direct data mode packet format.

**Figure 30-3. Direct Data Mode Packet Format**

The packet consists only of data bits and no header information. It can be 8-, 16- or 32-bit wide. A variable packet width is not supported because the DMM module will check the number of incoming bits (DMMCLK cycles) for error detection. The DMM will write the received data to the destination once the programmed number of bits has been received.

If the programmed word width does not correspond to the received data, the following actions will be taken:

- If the received data is greater than the programmed width, only the configured number of bits are transferred into the RAM buffer, the additional bits are discarded.
- If the received number of bits is smaller than the programmed width, no data will be written to the buffer, because a new DMMSYNC signal has been received before the expected number of bits.

### 30.2.2 Data Port

The packet will be received in several subpackets, depending on the width of the external data bus (DMMDATA[y:0]) and the amount of data to be transmitted. [Table 30-4](#) illustrates the number of clock cycles required for a complete packet.

**Table 30-4. Number of Clock Cycles per Packet**

| Port Width/ Pins | Write Size in Bits |    |    |    |
|------------------|--------------------|----|----|----|
|                  | 8                  | 16 | 32 | 64 |
| 1                | 32                 | 40 | 56 | 88 |
| 2                | 16                 | 20 | 28 | 44 |
| 4                | 8                  | 10 | 14 | 22 |
| 8                | 4                  | 5  | 7  | 11 |
| 16               | 2                  | 3  | 4  | 6  |

The user can program the port width in the DMMPC0 register ([Section 30.3.16](#)). This feature allows pins that are not used for DMM functionality to be used as GIO pins. Only the pins shown in [Table 30-5](#) can be used for a desired port width.

**Table 30-5. Pins Used for Data Communication**

| Port Width | Pins Used     |
|------------|---------------|
| 1          | DMMDATA[0]    |
| 2          | DMMDATA[1:0]  |
| 4          | DMMDATA[3:0]  |
| 8          | DMMDATA[7:0]  |
| 16         | DMMDATA[15:0] |

**NOTE:** If pins other than the ones specified in [Table 30-5](#) are programmed as functional pins for a desired port width, the received data will be corrupted and will not be transferred to the deserializer.

**NOTE:** If DMMCLK or DMMSYNC are programmed as nonfunctional pins, functional operation will not occur.

### 30.2.2.1 Signal Description

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMMSYNC                    | This signal has to be provided by external hardware. It signals the start of a new packet. It has to be active (high) for one full DMMCLK cycle, starting with the rising edge of DMMCLK. If the DMMSYNC pulse is longer than a single DMMCLK cycle and two falling edges of DMMCLK see a high pulse on DMMSYNC, the module will treat the second DMMSYNC pulse as the start of a packet and will flag a PACKET_ERR_INT (Section 30.3.5). |
| DMMCLK                     | The clock is externally generated and can be suspended between two packets. For this feature, CONTCLK must be set to 0 (Section 30.3.1). If the clock is not stopped between two packets, CONTCLK must be set to 1. Data will be latched on the falling edge of the DMMCLK signal.                                                                                                                                                        |
| $\overline{\text{DMMENA}}$ | This signal is pulled high if no new data should be received via the data pins, because of a potential overflow situation.                                                                                                                                                                                                                                                                                                                |
| DMMDATA[15:0]              | These pins receive the packet information transmitted by the external hardware. Data is latched on the falling edge of DMMCLK.                                                                                                                                                                                                                                                                                                            |

Figure 30-4 shows an example of multiple packets received during trace mode, in noncontinuous clock configuration.

**Figure 30-4. Packet Sync Signal Example**

Figure 30-5 shows an example of a 4-bit data port with 8-bit receive data (A5h) to be written into DEST1 (address 0001 2345h) on a trace mode packet.

**Figure 30-5. Example Single Packet Transmission**

### 30.2.3 Error Handling

The module will generate two different kind of errors. Once an error condition is recognized, an interrupt will be generated if enabled.

### 30.2.3.1 Overflow Error

This error is signaled when the module has received new data before the previous data was written to the destination address. If the internal buffers are full, the  $\overline{\text{DMMEN}}$  signal will go high. If the sending module does not evaluate the  $\overline{\text{DMMEN}}$  signal and keeps on sending new frames, the data that was previously received might be overwritten, thus resulting in setting the `BUFF_OVF` flag ([Section 30.3.5](#)).

### 30.2.3.2 Packet Error

#### Noncontinuous Clock Mode

The size of the incoming packet is defined by the `SIZE` information of a trace mode packet or the programmed size of a direct data mode packet. If too many or less than the number of bits are received before the next sync signal, the `PACKET_ERR_INT` flag will be set ([Section 30.3.5](#)). In case of receiving a `DMMCLK` signal without a corresponding `DMMSYNC` signal, a packet error will also be generated.

#### Continuous Clock Mode

If less than the expected number of bits are received, the `PACKET_ERR_INT` flag will be set ([Section 30.3.5](#)) when the next `DMMSYNC` signal is received. Packets with more than the expected number of bits cannot be detected.

The check for packet error is done only after the detection of the first `DMMSYNC` signal after the DMM is turned on or comes out of suspend mode (with `COS = 0`; [Section 30.3.1](#)), that is, before the reception of first `DMMSYNC`, the toggling of `DMMCLK` would be ignored.

### 30.2.3.3 Bus Error

If an error occurs on the microcontroller internal bus system while transferring the data from the DMM to the destination, the `BUSERROR` flag will be set.

## 30.2.4 Interrupts

The module provides different interrupts. These can be programmed to different interrupt levels independently using `DMMINTLVL` ([Section 30.3.4](#)).

Figure 30-6. Interrupt Structure

Interrupts can be divided into error interrupts and functional interrupts. The error handling is described in [Section 30.2.3](#). Functional interrupts depend on the mode (Trace Mode, Direct Data Mode) the DMM module is used in.

**Trace Mode:** An interrupt can be enabled whenever an access to the lowest address of a defined region is performed. This address is the starting address programmed in the `DMMDESTxREGy` register. An interrupt for each of the region can be generated by setting the individual interrupt enable bits.

**Direct Data Mode:** There are two interrupts that can be individually controlled. One is generated when the buffer pointer reaches the end of the defined buffer and wraps around (`EO_BUFF`; [Section 30.3.2](#)). The other one is generated when the buffer pointer matches the programmed interrupt threshold (`PROG_BUFF`; [Section 30.3.2](#)). The buffer pointer points to the next address to be written, therefore there are (interrupt threshold - 1) values stored in the buffer. The interrupt threshold can be programmed in the `DMMINTPT` register ([Section 30.3.11](#)).

### 30.3 Control Registers

This section describes the DMM registers. The registers support 8, 16, and 32-bit writes. The offset is relative to the associated peripheral select. [Table 30-6](#) provides a summary of the registers and their bits. The base address of the DMM module registers is FFFF F700h.

**Table 30-6. DMM Registers**

| Offset             | Acronym      | Register Description                            | Section                         |

Writes have no effect.                                                                                                                                                                                                                                                                                                                                             |
| 3-0  | ON/OFF    | All other<br>Ah<br>All other<br>Ah  | Switch module on or off<br>User and privilege mode (read):<br>The DMM module does not receive data.<br>The DMM module receives data and writes it to the buffer.<br>Privilege mode (write):<br>Disable receive/write operations. Packets in reception, will still be finished.<br>Enable receive/write operations. Packets will be received 1 HCLK cycle after enabling the module. |

---

**NOTE:** It is recommended to write 5h to ON/OFF to avoid having a soft error inadvertently enabling the module when a single bit flips.

---

---

**NOTE:** Registers that affect the operation of the module, should be only programmed when the BUSY bit is 0 and the ON/OFF bits are not Ah.

---

---

**NOTE:** If the module was in operation, turned off (ON/OFF = all other than Ah) and then turned on (ON/OFF = Ah) again, it is recommended to perform a reset (RESET = 1) of the module before switching it on. This avoids that the state machine is held in an unrecoverable state.

---

---

**NOTE:** A write to these register bits while receiving a packet will not have any effect on the received packet. The mode change will be performed after the packet is received

---

### 30.3.2 DMM Interrupt Set Register (DMMINTSET)

This register contains the interrupt set bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation.

**Figure 30-8. DMM Interrupt Set Register (DMMINTSET) [offset = 04h]**

|     |                |       | Privilege mode (write):                                                                                                                                                                                                                                                                                                                                             |
|     |                | 0     | No influence on bit.                                                                                                                                                                                                                                                                                                                                                |
|     |                | 1     | Enable interrupt (sets corresponding bit in DMMINTCLR; DMMINTLVL).                                                                                                                                                                                                                                                                                                  |
|     |                |       |                                                                                                                                                                                                                                                                                                                                                                     |

### 30.3.3 DMM Interrupt Clear Register (DMMINTCLR)

This register contains the interrupt clear bits for error interrupts and functional interrupts. Only the bits which are relevant for the particular mode (trace mode or direct data mode) will be taken into account for the interrupt generation

**Figure 30-9. DMM Interrupt Clear Register (DMMINTCLR) [offset = 08h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 30-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions**

| Bit   | Field     | Value | Description                                                                                                                                                                                                                                          |
|-------|-----------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-18 | Reserved  | 0     | Reads returns 0. Writes have no effect.                                                                                                                                                                                                              |
| 17    | PROG_BUFF |       | <b>Programmable Buffer Interrupt Set.</b> This disables the interrupt generation in case the buffer pointer equals the programmed value in the DMMINTPT register ( <a href="#">Section 30.3.11</a> ). This bit is only relevant in Direct Data Mode. |
|       |           |       | User and privilege mode (read):                                                                                                                                                                                                                      |
|       |           | 0     | No interrupt will be generated.                                                                                                                                                                                                                      |
|       |           | 1     | An interrupt will be generated on pointer match.                                                                                                                                                                                                     |
| 16    | EO_BUFF   |       | Privilege mode (write):                                                                                                                                                                                                                              |
|       |           | 0     | No influence on bit.                                                                                                                                                                                                                                 |
|       |           | 1     | Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                                                                                                                                 |
|       |           |       | <b>End of Buffer Interrupt Set.</b> This disables the interrupt generation in case data was written to the last entry in the buffer and the pointer wrapped around to the beginning of the buffer. This bit is only relevant in Direct Data Mode.    |
|       |           |       | User and privilege mode (read):                                                                                                                                                                                                                      |
|       |           | 0     | No interrupt will be generated.                                                                                                                                                                                                                      |
|       |           | 1     | An interrupt will be generated on writing to the last entry.                                                                                                                                                                                         |
|       |           |       | Privilege mode (write):                                                                                                                                                                                                                              |
|       |           | 0     | No influence on bit.                                                                                                                                                                                                                                 |
|       |           | 1     | Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                                                                                                                                 |

**Table 30-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                                                            |
|-----|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | DEST3REG2 |       | <b>Destination 3 Region 2 Interrupt Set.</b> This disables the interrupt generation in case data was accessed at the start address of Destination 3 Region 2. This bit is only relevant in Trace Mode. |
|     |           |       | User and privilege mode (read):                                                                                                                                                                        |
|     |           | 0     | No interrupt will be generated.                                                                                                                                                                        |
|     |           | 1     | An interrupt will be generated on a write to the start address of this region.                                                                                                                         |
| 14  | DEST3REG1 |       | <b>Destination 3 Region 1 Interrupt Set.</b> This disables the interrupt generation in case data was accessed at the start address of Destination 3 Region 1. This bit is only relevant in Trace Mode. |
|     |           |       | User and privilege mode (read):                                                                                                                                                                        |
|     |           | 0     | No interrupt will be generated.                                                                                                                                                                        |

| 2   | DMMINTCLR |       | <b>DMM Interrupt Clear Register.</b> This register clears the DMM Interrupt Level Register (DMMINTLVL) bits. This register is only relevant in Trace Mode.                                             |
|     |           |       | User and privilege mode (read):                                                                                                                                                                        |
|     |           | 0     | No influence on bit.                                                                                                                                                                                   |
|     |           | 1     | Disable interrupt (clears corresponding bit in DMMINTLVL).                                                                                                                                             |
| 1   | DMMINTCLR |       | <b>DMM Interrupt Clear Register.</b> This register clears the DMM Interrupt Level Register (DMMINTLVL) bits. This register is only relevant in Trace Mode.                                             |
|     |           |       | User and privilege mode (read):                                                                                                                                                                        |
|     |           | 0     | No influence on bit.                                                                                                                                                                                   |
|     |           | 1     | Disable interrupt (clears corresponding bit in DMMINTLVL).                                                                                                                                             |
| 0   | DMMINTCLR |       | <b>DMM Interrupt Clear Register.</b> This register clears the DMM Interrupt Level Register (DMMINTLVL) bits. This register is only relevant in Trace Mode.                                             |
|     |           |       | User and privilege mode (read):                                                                                                                                                                        |
|     |           | 0     | No influence on bit.                                                                                                                                                                                   |
|     |           | 1     | Disable interrupt (clears corresponding bit in DMMINTLVL).                                                                                                                                             |

**Table 30-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                                                            |
|-----|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | DEST1REG1 |       | <b>Destination 1 Region 1 Interrupt Set.</b> This enables the interrupt generation in case data was accessed at the start address of Destination 1 Region 1. This bit is only relevant in Trace Mode.  |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                     |
|     |           | 1     | An interrupt will be generated on a write to the start address of this region.                                                                                                                         |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                            |
| 9   | DEST0REG2 |       | <b>Destination 0 Region 2 Interrupt Set.</b> This disables the interrupt generation in case data was accessed at the start address of Destination 0 Region 2. This bit is only relevant in Trace Mode. |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                     |
|     |           | 1     | An interrupt will be generated on a write to the start address of this region.                                                                                                                         |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                            |
| 8   | DEST0REG1 |       | <b>Destination 0 Region 1 Interrupt Set.</b> This disables the interrupt generation in case data was accessed at the start address of Destination 0 Region 1. This bit is only relevant in Trace Mode. |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                     |
|     |           | 1     | An interrupt will be generated on a write to the start address of this region.                                                                                                                         |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                            |
| 7   | BUSERROR  |       | <b>Bus Error Response</b> for errors generated when doing internal bus transfers.                                                                                                                      |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                     |
|     |           | 1     | An interrupt will be generated.                                                                                                                                                                        |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                            |
| 6   | BUFF_OVF  |       | <b>Buffer Overflow.</b> This disables the interrupt generation in case new data is received, while the previous data still has not been transmitted.                                                   |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                     |
|     |           | 1     | An interrupt will be generated.                                                                                                                                                                        |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                            |

**Table 30-9. DMM Interrupt Clear Register (DMMINTCLR) Field Descriptions (continued)**

| Bit | Field     | Value | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----|-----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | SRC_OVF   |       | <b>Source Overflow.</b> This disables an interrupt if the external system experienced an overflow which was signaled in the Trace Mode packet.                                                                                                                                                                                                                        |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                                                                                                                                                                                    |
|     |           | 1     | An interrupt will be generated.                                                                                                                                                                                                                                                                                                                                       |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                                                                                                                                                                                           |
| 4   | DEST3_ERR |       | <b>Destination 3 Error.</b> This disables the interrupt generation in case data should be written into an address not specified by DMMDEST3REG1/DMMDEST3BL1 or DMMDEST3REG2/DMMDEST3BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place.               |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                                                                                                                                                                                    |
|     |           | 1     | An interrupt will be generated.                                                                                                                                                                                                                                                                                                                                       |
|     |           |       | Privilege mode (write):<br>0 No influence on bit.<br>1 Disable interrupt (clears corresponding bit in DMMINTCLR; DMM Interrupt Level Register (DMMINTLVL)).                                                                                                                                                                                                           |
| 3   | DEST2_ERR |       | <b>Destination 2 Error Interrupt Set.</b> This disables the interrupt generation in case data should be written into an address not specified by DMMDEST2REG1/DMMDEST2BL1 or DMMDEST2REG2/DMMDEST2BL2. If both block sizes are programmed to 0 or a reserved value, the interrupt will still be generated, the write to the internal RAM however will not take place. |
|     |           | 0     | User and privilege mode (read):<br>No interrupt will be generated.                                                                                                                                                                                                                                                                                                    |

### 30.3.4 DMM Interrupt Level Register (DMMINTLVL)

This register contains the interrupt level bits for error interrupts and normal interrupts.

**Figure 30-10. DMM Interrupt Level Register (DMMINTLVL) [offset = 0Ch]**

### 30.3.5 DMM Interrupt Flag Register (DMMINTFLG)

This register contains the interrupt level bits for error interrupts and normal interrupts.

### 30.3.6 DMM Interrupt Offset 1 Register (DMMOFF1)

This register holds the offset indicating which interrupt occurred on interrupt level 0. The CPU can read this register to determine the source of the interrupt without having to test individual interrupt flags.

**Figure 30-12. DMM Interrupt Offset 1 Register (DMMOFF1) [offset = 14h]**

LEGEND: R = Read only; -n = value after reset

**Table 30-12. DMM Interrupt Offset 1 Register (DMMOFF1) Field Descriptions**

| Bit  | Field    | Value                                                                                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 30.3.8 DMM Direct Data Mode Destination Register (DMMDDMDEST)

This register defines the starting address of the buffer used to store the received data in Direct Data Mode. By writing to this register, the DMMDDMPT register ([Section 30.3.10](#)) will be set to 0x0000.

**Figure 30-14. DMM Direct Data Mode Destination Register (DMMDDMDEST) [offset = 1Ch]**

**Table 30-16. DMM Direct Data Mode Pointer Register (DMMDDMPT) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                          |
|-------|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                               |
| 14-0  | POINTER  |       | These bits hold the pointer to the next entry to be written in the buffer. The pointer points to the byte aligned address. If in 16-bit DDM mode, bit 0 will be 0. If in 32-bit DDM mode, bit 0 and 1 will be 0.<br>User and privilege mode (read): next data entry<br>Privilege mode (write): writes have no effect |

### 30.3.11 DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT)

This register can be programmed to hold a threshold to which the DMMDDMPT register (Section 30.3.10) is compared. An interrupt can be generated when both match.

**Figure 30-17. DMM Direct Data Mode Interrupt Pointer Register (DMMINTPT) [offset = 28h]**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                            |
|-------|----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-15 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                 |
| 14-0  | INTPT    |       | Interrupt Pointer. When the buffer pointer (Section 30.3.10) matches the programmed value in DMMINTPT and the PROG_BUF interrupt (Section 30.3.2) is set, an interrupt is generated.<br>User and privilege mode (read): current interrupt threshold<br>Privilege mode (write): new interrupt threshold |

### 30.3.12 DMM Destination x Region 1 (DMMDESTxREG1)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG1 and DMMDESTxBL1, an interrupt (DESTx\_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG1, DMMDEST1REG1, DMMDEST2REG1, DMMDEST3REG1.

**Figure 30-18. DMM Destination x Region 1 (DMMDESTxREG1) [offset = 2Ch, 3Ch, 4Ch, 5Ch]**

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -n = value after reset

**Table 30-18. DMM Destination x Region 1 (DMMDESTxREG1) Field Descriptions**

| Bit   | Field     | Description                                                                                                                                                                                                                                                                                                           |

### 30.3.14 DMM Destination x Region 2 (DMMDESTxREG2)

This register defines the starting address of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG2 and DMMDESTxBL2, an interrupt (DESTx\_ERR) can be generated. The description below is valid for following registers: DMMDEST0REG2, DMMDEST1REG2, DMMDEST2REG2, DMMDEST3REG2.

**Figure 30-20. DMM Destination x Region 2 (DMMDESTxREG2) [offset = 34h, 44h, 54h, 64h]**

LEGEND: R/W = Read/Write; WP = Write in privilege mode only; -n = value after reset

**Table 30-20. DMM Destination x Region 2 (DMMDESTxREG2) Field Descriptions**

### 30.3.15 DMM Destination x Blocksize 2 (DMMDESTxBL2)

This register defines the blocksize of the buffer used to store the received data in Trace Mode. If the received data does not fall into the address range defined by DMMDESTxREG2 and DMMDESTxBL2, an interrupt (DESTx\_ERR) can be generated. The description below is valid for following registers: DMMDEST0BL2, DMMDEST1BL2, DMMDEST2BL2, DMMDEST3BL2.

### 30.3.16 DMM Pin Control 0 (DMMPC0)

This register defines if the DMM pins are used in functional or GIO mode. It should only be written when ON/OFF = 0101 and the BUSY bit = 0 (Section 30.3.1). If pins other than the pins specified in Table 30-5 are configured, or DMMCLK and DMMSYNC are programmed as non-functional pins, no operation in trace mode or direct data mode is possible.

|     |          | 0     | Pin is used in GIO mode.                                                                                           |
|     |          | 1     | Pin is used in Functional mode.                                                                                    |

### 30.3.17 DMM Pin Control 1 (DMMP1)

The bits in this register define the direction of the individual module pins when in GIO mode.

### 30.3.18 DMM Pin Control 2 (DMMPC2)

The bits in this register reflect the digital representation of the voltage level at the module pins. Even if a pin is configured to be an output pin, the level can be read back via this register.

**Figure 30-24. DMM Pin Control 2 (DMMPC2) [offset = 74h]**

### 30.3.20 DMM Pin Control 4 (DMMP4)

This register allows to set individual pins to a logic high level without having to do a read-modify-write operation as would be the case with the DMMP3 register ([Section 30.3.19](#)). Writing a zero to a bit will not change the state of the pin.

**Figure 30-26. DMM Pin Control 4 (DMMP4) [offset = 7Ch]**

### 30.3.21 DMM Pin Control 5 (DMMPC5)

This register allows to set individual pins to a logic low level without having to do a read-modify-write operation as would be the case with the DMMPC3 register ([Section 30.3.19](#)). Writing a one to a bit will change the output to a logic low level, writing a zero will not change the state of the pin.

### 30.3.22 DMM Pin Control 6 (DMMP6)

These bits configure the pins in push-pull or open-drain functionality. If configured to be open-drain, the module only drives a logic-low level on the pin. An external pull-up resistor needs to be connected to the pin to pull it high, when the pin is in high-impedance mode.

### 30.3.23 DMM Pin Control 7 (DMMP7)

The bits in register control the pullup/down functionality of a pin. The internal pullup/down can be enabled or disabled by this register. The reset configuration of these bits is device implementation dependent. Please consult the device datasheet for this information.

**Figure 30-29. DMM Pin Control 7 (DMMP7) [offset = 88h]**

## ***RAM Trace Port (RTP)***

---

---

---

This chapter describes the functionality of the RAM trace port (RTP) module. It allows the capability to perform data trace of a CPU or other master accesses to the internal RAM and peripherals.

| <b>Topic</b>                       | <b>Page</b> |
|------------------------------------|-------------|
| <b>31.1 Overview.....</b>          | <b>1706</b> |
| <b>31.2 Module Operation .....</b> | <b>1707</b> |
| <b>31.3 GPIO Function .....</b>    | <b>1713</b> |
| <b>31.4 Control Registers.....</b> | <b>1713</b> |

## 31.1 Overview

This chapter describes the functionality of the RAM trace port (RTP) module, which provides the features to datalog the RAM contents of the devices or accesses to peripherals without program intrusion. It can trace all data write or read accesses to internal RAM. In addition, it provides the capability to directly transfer data to a FIFO to support a CPU-controlled transmission of the data. The trace data is transmitted over a dedicated external interface.

### 31.1.1 Features

The RTP offers the following features:

- Two modes of operation - Trace Mode and Direct Data Mode
  - Trace Mode ([Section 31.2.1](#))
    - Non-intrusive data trace on write or read operation
    - Visibility of RAM content at any time on external capture hardware
    - Trace of peripheral accesses
    - 2 configurable trace regions for each RAM module to limit amount of data to be traced
    - FIFO to store data and address of data of multiple read/write operations
    - Trace of CPU and/or DMA accesses with indication of the master in the transmitted data packet
  - Direct Data Mode ([Section 31.2.2](#))
    - Directly write data with the CPU or trace read operations to a FIFO, without transmitting header and address information
- Dedicated synchronous interface to transmit data to external devices
- Free-running clock generation or clock stop mode between transmissions
- up to 100 Mbit per sec/pin transfer rate for transmitting data (up to 133MB/s; see device datasheet for maximum transmission clock frequency)
- Pins not used in functional mode can be used as GIOs

### 31.1.2 Block Diagram

**Figure 31-1. Block Diagram RAM Trace Port Module**

## 31.2 Module Operation

The RTP module has two modes of operation: Trace Mode and Direct Data Mode.

### 31.2.1 Trace Mode

This mode traces all write or read accesses of CPU and/or a different master to the internal RAMs and the peripheral bus, if the access falls into one of the programmed trace regions. The trace regions allow to restrict the amount of data which is traced. This is done by specifying the start address and the size of the region to be traced. It is not possible to trace write and read operations in the same region at the same time.

Whenever a write or read access occurs, the address, data, size of the access (8, 16, 32, 64 bit), and which module initiated the write or read operation is captured into the FIFO of the corresponding RAM frame. Once new data is in the FIFO and the serializer is empty, the RTP transmits the data into the serializer and starts transmitting it.

The FIFOs are shifting data into the serializer in a round-robin scheme. This means if data is available in multiple FIFOs, the sequence for shifting data into the serializer is FIFO1, FIFO2 and then FIFO4. Only one entry in the respective FIFO is provided to the serializer before switching to the next FIFO. If a FIFO does not hold new data, it will be skipped. This scheme ensures that the FIFOs are drained uniformly.

#### 31.2.1.1 Packet Format in Trace Mode

Figure 31-2 and Figure 31-3 illustrate this format.

Figure 31-2. Packet Format Trace Mode for RAM Locations

Figure 31-3. Packet Format Trace Mode for Peripheral Locations

When RAM locations are traced, one packet consists of two bits denoting the RAM block in which the data is stored or if the access has been to a peripheral location (Table 31-1), two status bits showing the access initiator or if there was a FIFO overflow (Table 31-2), two bit size (8, 16, 32, or 64 bit) information of the data (Table 31-3), the 18-bit address for RAM accesses and  $2^{\text{SIZE}} \times 8$  bits of data. If a peripheral location is traced, then the effective address reduces to 17 bits (ADDR[16:0]) and a separate bit (REG) between the SIZE information and the address denotes which programmable region has traced this peripheral access (Table 31-4). With the region identifier, the external hardware can determine which peripheral was traced.

Table 31-1. Encoding of RAM Bits in Trace Mode Packet Format

| RAM[1:0] | RAM             |
|----------|-----------------|
| 0        | Cortex-R4 B0TCM |
| 1h       | Cortex-R4 B1TCM |
| 2h       | Reserved        |
| 3h       | Peripherals     |

**Table 31-2. Encoding of Status Bits in Trace Mode Packet Format**

| STAT[1:0] | Status                         |
|-----------|--------------------------------|
| 0         | normal entry CPU               |
| 1h        | normal entry other Master      |
| 2h        | reserved                       |
| 3h        | overflow of the dedicated FIFO |

In the event of a FIFO overflow, an overflow will be signaled in the status bits of the next transmitted packet of that particular FIFO. The last entry in the FIFO will not be overwritten by the new data.

**Table 31-3. Encoding of SIZE bits in Trace Mode Packet Format**

| SIZE[1:0] | Write/Read Size |
|-----------|-----------------|
| 0         | 8 bit           |
| 1h        | 16 bit          |
| 2h        | 32 bit          |
| 3h        | 64 bit          |

**Table 31-4. Encoding of REG in Trace Mode Packet Format**

| REG | Region |
|-----|--------|
| 0   | 1      |
| 1   | 2      |

The packet will be split up into several subpackets when transmitted over the RTP port pins depending on the port width configured. The port width is configured with bits PW[1:0] in the RTPGLBCTRL register ([Section 31.4.1](#)). For certain port width configurations and write/read sizes, the number of bits in a packet does not exactly match the port width for the last subpacket. The remaining bits will be filled with zeros.

**Table 31-5. Number of Transfers/Packet**

| Port Width | Write/Read Size in bits |           |           |           |
|------------|-------------------------|-----------|-----------|-----------|
|            | 8                       | 16        | 32        | 64        |
| 2          | 16 --> 16               | 20 --> 20 | 28 --> 28 | 44 --> 44 |
| 4          | 8 --> 8                 | 10 --> 10 | 14 --> 14 | 22 --> 22 |
| 8          | 4 --> 4                 | 5 --> 5   | 7 --> 7   | 11 --> 11 |
| 16         | 2 --> 2                 | 2.5 --> 3 | 3.5 --> 4 | 5.5 --> 6 |

Example: For a 16-bit port and with data of 16-bit, the last transfer has to be padded with eight 0s. This effectively results in a transfer of 48 bits instead of 40. However the whole transfer is completed in 3 RTPCLK cycles.

For a detailed description of the representation of the packet on the RTP port pins, please refer to [Section 31.2.5](#).

### 31.2.2 Direct Data Mode (DDM)

In this mode, data is written directly by the CPU or other master to a dedicated capture register (RTPDDMW). The data is then transferred from the capture register to the FIFO. In a different configuration the module traces the data on read operations on the RAM directly into the FIFOs. In Direct Data Mode, no information other than the actual data is transmitted. The address of the written data can only be determined by the order of writes or reads by the CPU or other master. This mode is especially useful if a block of data on consecutive addresses has to be transmitted.

The transfer size (8, 16, or 32 bit) is programmable, but cannot be dynamically changed. Data not written/read in the correct transfer size will be truncated/extended. For example, if the transfer size is programmed to 16 bits and a 32-bit write operation is performed, the data written to the FIFO will be 32-bit wide, however only the upper 16 bits of the FIFO will be transmitted. If an 8-bit operation is performed, bits 8-15 of the FIFO will be indeterminate, so the upper 8 bits of the data transmitted are dependent on the previous contents of the FIFO RAM.

When the module is configured in Direct Data Mode (TM\_DDM = 1) to trace write operations (DDM\_RW = 1) to the RTPDDMW register, the programming of the trace regions for all FIFOs will be ignored and data tracing, when accessing the addresses defined by the regions, will not occur. If the module is configured in read mode (DDM\_RW = 0), and if the read access to a RAM block falls into a valid trace region, the data will be traced into the corresponding FIFO for this RAM block. Since no address information is transmitted in Direct Data Mode, the executing program has to make sure that one FIFO is completely empty (RTPGSR), before new data is traced into the next FIFO.

---

**NOTE:** Direct Data Mode read operation is not supported on devices with a Cortex-R4 CPU, due to the bus protocol of the TCM interface and certain performance enhancements (for example, data packing) implemented in the core.

---

#### 31.2.2.1 Packet Format in Direct Data Mode

In Direct Data Mode write or read operations, only the data written to the RTPDDMW register or the data read from RAM, and therefore captured into the FIFO, will be transmitted. The packet length is programmable (8, 16, or 32 bits). Figure 31-4 illustrates this format.

**Figure 31-4. Packet Format in Direct Data Mode**

### 31.2.3 Trace Regions

To limit the amount of data to be trace, two trace regions per RAM or peripheral are implemented. These can be programmed to specific start addresses and block sizes. Depending on the device configuration (number of RAM blocks), not all regions might be implemented. Trace regions are used in Trace Mode for read or write trace and in Direct Data Mode for read trace. In Direct Data Mode write configuration, the data has to be written directly to RTPDDMW.

The RAM and peripherals start at fixed addresses in the devices memory map. With this the start address of a region does not need to be specified with its full 32-bit address. For RAM regions, only the lower 18-bit need to be programmed. The peripheral address frame covers a wider range and the start address needs to be programmed with the lower 24-bit.

The trace regions do not support a programmable end address; however, a block size needs to be specified for each region. The block size can be chosen from as low as 256 Bytes up to 256 kBytes (128 kBytes for peripherals).

### 31.2.3.1 Inverse Trace Regions

The RTP can be configured to trace accesses which fall into, or are made outside of the specified regions. This can be accomplished by the INV\_RGN bit. If this bit is 0, all access which are made inside a region are traced. If the bit is 1, all accesses outside the region are traced. The INV\_RGN bit affects all regions of the RTP (see [RTPGLBCTRL](#)).

There are certain restrictions when using INV\_RGN = 1:

- In this mode up to 2 regions can be excluded from tracing accesses to a particular RAM.
- Inverse trace regions with one or both regions of a RAM programmed with blocksize = 0 is not supported. If only one address range should be excluded from the trace, either the address range has to be covered by both regions (for example, excluding 1kB range with two 512B regions), or both regions have to be programmed with the same start address and region size. If the whole RAM should be traced, inverse region mode should not be used, instead the 2 regions could be programmed to cover the entire address range with INV\_RGN = 0.
- Both regions have to define the same access rights (bits CPU\_DMA and RW; see [Section 31.4.4](#)) for accesses outside of the region of each RAM block, otherwise the result is undefined.
- Peripheral trace in inverse region mode is not supported. The 16 MByte peripheral address range cannot be covered entirely by the 17 bit address definition of the RTP protocol.

### 31.2.3.2 Overlapping Trace Regions

When in INV\_RGN = 0 mode with both regions overlapping and an access is done into the overlapping address range, both regions will be checked for their access rights and if one or both is satisfied, the access will be traced. In the case that both regions would allow the data to be traced, there will still be only one entry into the FIFO.

If accesses to peripherals are done within overlapping regions, the REG bit in the protocol will be 0, denoting Region 1 (see [Section 31.2.1.1](#)).

**Figure 31-5. Example for Trace Region Setup**

### 31.2.3.3 Cortex-R4 Specifics

Due to the bus system used on Cortex-R4, special considerations have to be taken into account. [Figure 31-1](#) shows the block diagram of the RTP connected to the Cortex-R4 RAM interface.

Both interfaces to RAM0 and RAM1 are 64-bit wide. RAM0 and RAM1 are building a consecutive address range, where the 64-bit addresses 00, 10h, 20h, ... reside in RAM0 and 08h, 18h, 28h, ... reside in RAM1.

#### Considerations/Restrictions

- To trace a certain address range, the regions of both RAM0 ([Section 31.4.4](#)) and RAM1 ([Section 31.4.5](#)) need to be set up for the same start address and region size. Otherwise only every other 64-bit access will be traced.
- Direct Data Mode read operation is not supported on Cortex-R4. This is because the CPU uses 64-bit accesses for read operations even though the intended accesses is sub-64-bit wide. Since Direct Data Mode only supports 32-bit data transfers and the Cortex-R4 RAM interface does not provide information about which byte out of the 64-bit is accessed with the read operation, the RTP cannot determine the correct data value.
- If the RAM is protected by ECC, only 64-bit write accesses can be traced. Every 64-bit word in the RAM is protected by a corresponding 8-bit ECC checksum. When a sub-64-bit write access is performed, the Cortex-R4 has to do a read-modify-write operation of the 64-bit word to be modified in order to calculate the corresponding checksum and then write it back to memory. External hardware can still determine which portion of the 64-bit word has been modified, since the other bytes in this word did not change.

### 31.2.4 Overflow/Empty Handling

In case the application does RAM accesses faster than the FIFO can be emptied via the external pin interface, the FIFO can overflow. The user can choose whether the program execution/data transfer should be suspended, or an overflow should be signaled in the status bits of the next, to be transmitted, message of this particular FIFO. If program execution is resumed, the data will be lost. The overflow will not be signaled in the message that is already in the serializer and being transmitted when the overflow occurs.

**NOTE:** The status information will only be transmitted in Trace Mode, since the Direct Data Mode packet does not contain any status information.

When an overflow in a FIFO occurs, the corresponding bit in [RTPGSR](#) will be set.

**Figure 31-6. FIFO Overflow Handling**

### 31.2.5 Signal Description

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTPCLK                     | This clock signal is used to clock out the data of the serializer. Depending on the CONTCLK bit, the clock can be suspended between packets or it can be free running. The RTPCLK frequency can be adjusted by the PRESCALER bits (see <a href="#">Section 31.4.1</a> ).                                                                                                                                                                                                                                                                                                                                      |
| RTPSYNC                    | The module provides a packet-sync signal. This signal will go high on the rising edge of RTPCLK and will be valid for one RTPCLK cycle to synchronize external hardware to the data stream. The RTPSYNC pulse will be generated for each new packet.                                                                                                                                                                                                                                                                                                                                                          |
| $\overline{\text{RTPENA}}$ | This signal is an input and can be used by external hardware to stop the data transmission between packets. When the $\overline{\text{RTPENA}}$ signal goes high, the RTP will finish the current packet transmission and then stop. Once the signal is pulled low again, the RTP will resume the transfer if data is still present in the serializer or FIFOs. The $\overline{\text{RTPENA}}$ signal does not have to be used for proper module operation. It can be used in GIO mode if the external hardware cannot generate this signal. Overflows of the external system cannot be handled in this case. |
| RTPDATA[15:0]              | These pins are used to do the actual data transfer. Data changes with the rising edge of RTPCLK. The port can be configured for different widths (PW[1:0]). The minimum port width supported is 2 pins. See <a href="#">Table 31-9</a> which pins are used for the port.                                                                                                                                                                                                                                                                                                                                      |

[Figure 31-7](#) shows an example of multiple packet transmissions in Trace Mode with an interruption between packets because of  $\overline{\text{RTPENA}}$  pulled high.

**Figure 31-7. RTP Packet Transfer with Sync Signal**

[Figure 31-8](#) shows an example of a 4-bit data port with 8-bit write data (A5h) written into RAM1 (address 12345h) with no overflow in trace mode.

**Figure 31-8. Packet Format in Trace Mode**

### 31.2.6 Data Rate

The module is configurable to support different RTPCLK frequencies. Please see the device datasheet for the maximum supported frequency. HCLK will be prescaled to achieve the desired RTPCLK frequency. The prescaler supports prescale values from 1 to 8 ([Section 31.4.1](#)).

The effective bandwidth depends on the configuration of the module and the average data width transmitted in the packets.

### 31.3 GIO Function

Pins which are not used for RTP functionality can be used as normal GIO pins. If pins should be used in functional mode or GIO mode, they can be programmed in [RTPPC0](#). The direction of the pins can be chosen in [RTPPC1](#).

Module pins can have either an internal pullup or active pulldown that makes it possible to leave the pins unconnected externally when configured as inputs. The pins can be programmed to have the active pull capability by writing a 0 to the corresponding bit in the [RTPPC7](#) register. Writing a 1 to the corresponding bit disables the active pull functionality of the pin. A pull up can be configured by writing 1 to the corresponding bit in the [RTPPC8](#) register. Writing 0 will activate the pulldown capability. The pullup/pulldown is deactivated when a bidirectional pin is configured as an output.

The GIO pin can be configured to include an open drain functionality when they are configured as output pins. This is done by writing a 1 into the corresponding bit of the [RTPPC6](#) register. When the open drain functionality is enabled, a zero written to the data output register ([RTPPC3](#)) forces the pin to a low output voltage ( $V_{OL}$  or lower), whereas writing a 1 to the data output register ([RTPPC3](#)) forces the pin to a high impedance state. The open drain functionality is disabled when the pin is configured as an input pin.

### 31.4 Control Registers

This section describes the RTP module registers. The registers support 8-bit, 16-bit, and 32-bit writes. The base address of the RTP module registers is FFFF FA00h.

**Table 31-6. RTP Module Registers**

| Offset   | Acronym    | Register Description                 | Section                         |
|----------|------------|--------------------------------------|---------------------------------|
| 00h      | RTPGLBCTRL | RTP Global Control Register          | <a href="#">Section 31.4.1</a>  |
| 04h      | RTPTRENA   | RTP Trace Enable Register            | <a href="#">Section 31.4.2</a>  |
| 08h      | RTPGSR     | RTP Global Status Register           | <a href="#">Section 31.4.3</a>  |
| 0Ch, 10h | RTPRAM1REG | RTP RAM 1 Trace Region Register      | <a href="#">Section 31.4.4</a>  |
| 14h, 18h | RTPRAM2REG | RTP RAM 2 Trace Region Register      | <a href="#">Section 31.4.5</a>  |
| 24h, 28h | RTPPERREG  | RTP Peripheral Trace Region Register | <a href="#">Section 31.4.6</a>  |
| 2Ch      | RTPDDMW    | RTP Direct Data Mode Write Register  | <a href="#">Section 31.4.7</a>  |
| 34h      | RTPPC0     | RTP Pin Control 0 Register           | <a href="#">Section 31.4.8</a>  |
| 38h      | RTPPC1     | RTP Pin Control 1 Register           | <a href="#">Section 31.4.9</a>  |
| 3Ch      | RTPPC2     | RTP Pin Control 2 Register           | <a href="#">Section 31.4.10</a> |
| 40h      | RTPPC3     | RTP Pin Control 3 Register           | <a href="#">Section 31.4.11</a> |
| 44h      | RTPPC4     | RTP Pin Control 4 Register           | <a href="#">Section 31.4.12</a> |
| 48h      | RTPPC5     | RTP Pin Control 5 Register           | <a href="#">Section 31.4.13</a> |
| 4Ch      | RTPPC6     | RTP Pin Control 6 Register           | <a href="#">Section 31.4.14</a> |
| 50h      | RTPPC7     | RTP Pin Control 7 Register           | <a href="#">Section 31.4.15</a> |
| 54h      | RTPPC8     | RTP Pin Control 8 Register           | <a href="#">Section 31.4.16</a> |

### 31.4.1 RTP Global Control Register (RTPGLBCTRL)

The configuration of the module can be changed with this register. [Figure 31-9](#) and [Table 31-7](#) illustrate this register.

**Figure 31-9. RTP Global Control Register (RTPGLBCTRL) [offset = 00h]**

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 31-7. RTP Global Control Register (RTPGLBCTRL) Field Descriptions**

| Bit   | Field     | Value    | Description                                                                                                                                                                                                                                                                                                 |
|-------|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved  | 0        | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                      |
| 24    | TEST      | 0        | By setting the bit, the FIFO RAM will be mapped into the SYSTEM Peripheral frame starting at address FFF8 3000h. Each FIFO will start at a 1k boundary. Each FIFO entry will be aligned to a 128 bit boundary. See <a href="#">Table 31-8</a> for a listing of the FIFOs and their corresponding addresses. |
|       |           | 1        | User and privilege mode (read):<br>The FIFO RAM is mapped to address FFF8 3000h.                                                                                                                                                                                                                            |
|       |           | 0        | Privilege mode (write):<br>Disables mapping of the FIFO RAM.                                                                                                                                                                                                                                                |
|       |           | 1        | Enables mapping of the FIFO RAM into address FFF8 3000h.                                                                                                                                                                                                                                                    |
| 18-16 | PRESCALER | 0        | The prescaler divides HCLK down to the desired RTPCLK frequency. The maximum RTPCLK frequency specified in the device datasheet must not be exceeded. No dynamic change of RTPCLK is supported. The module should be switched off by the ON/OFF bits in this register before changing the prescaler.        |
|       |           | 1h       | User and privilege mode read, privilege mode write:<br>The prescaler is HCLK/2.                                                                                                                                                                                                                             |
|       |           | 2h       | The prescaler is HCLK/3.                                                                                                                                                                                                                                                                                    |
|       |           | 3h       | The prescaler is HCLK/4.                                                                                                                                                                                                                                                                                    |
|       |           | 4h       | The prescaler is HCLK/5.                                                                                                                                                                                                                                                                                    |
|       |           | 5h       | The prescaler is HCLK/6.                                                                                                                                                                                                                                                                                    |
|       |           | 6h       | The prescaler is HCLK/7.                                                                                                                                                                                                                                                                                    |
|       |           | 7h       | The prescaler is HCLK/8.                                                                                                                                                                                                                                                                                    |
| 15-14 | Reserved  | 0        | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                      |
| 13-12 | DDM_WIDTH | 0        | Direct data mode word size width. This bit field configures the number of bits that will be transmitted in Direct Data Mode.                                                                                                                                                                                |
|       |           | 1h       | User and privilege mode read, privilege mode write:<br>The word size width is 8 bits.                                                                                                                                                                                                                       |
|       |           | 2h       | The word size width is 16 bits.                                                                                                                                                                                                                                                                             |
|       |           | 3h       | The word size width is 32 bits.                                                                                                                                                                                                                                                                             |
|       |           | Reserved |                                                                                                                                                                                                                                                                                                             |

|     |         |       | User and privilege mode (read):                                                                                                                                                                                                                                                                                                                                          |
|     |         | 0     | The current data transfer to the FIFO will not be suspended in case of a full FIFO.                                                                                                                                                                                                                                                                                      |
|     |         | 1     | The current data transfer to the FIFO will be suspended in case of a full FIFO.                                                                                                                                                                                                                                                                                          |
| 5   | HOVF    |       | Privilege mode (write):                                                                                                                                                                                                                                                                                                                                                  |
|     |         | 0     | The halt on FIFO overflow will be disabled. The data transfer will not be suspended and will be discarded. Data written to the RTPDDMW register will overwrite the <a href="#">RTPDDMW</a> register.                                                                                                                                                                     |
|     |         | 1     | The halt on FIFO overflow will be enabled. Data written to the already full FIFO will be written once the FIFO is emptied again. The data transfer to the FIFO will be suspended and signaled to the CPU or other master while there is still data to be shifted out. When there is an empty FIFO location again, the transfer of the data to the FIFO will be finished. |
|     |         |       |                                                                                                                                                                                                                                                                                                                                                                          |

**Table 31-7. RTP Global Control Register (RTPGLBCTRL) Field Descriptions (continued)**

| Bit | Field   | Value      | Description                                                                                                                                                                                                                |
|-----|---------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4   | INV_RGN |            | Trace inside or outside of defined trace regions.                                                                                                                                                                          |
|     |         |            | User and privilege mode (read):                                                                                                                                                                                            |
|     |         | 0          | Accesses inside the trace regions are traced.                                                                                                                                                                              |
|     |         | 1          | Accesses outside the trace regions are traced.                                                                                                                                                                             |
| 3-0 | ON/OFF  |            | Privilege mode (write):                                                                                                                                                                                                    |
|     |         | 0          | Allow tracing of accesses inside the regions set in RTPRAMxREGy                                                                                                                                                            |
|     |         | 1          | Allow tracing of accesses outside the regions set in RTPRAMxREGy ( <a href="#">Section 31.4.4</a> )                                                                                                                        |
|     |         |            | ON/Off switch.                                                                                                                                                                                                             |
|     |         |            | User and privilege mode (read):                                                                                                                                                                                            |
|     |         | Ah         | Tracing of data is enabled.                                                                                                                                                                                                |
|     |         | All Others | Tracing of data is disabled.                                                                                                                                                                                               |
|     |         |            | Privilege mode (write):                                                                                                                                                                                                    |
|     |         | Ah         | Enable Tracing of data. If there is any previous captured data remaining, it will be shifted out.                                                                                                                          |
|     |         | All Others | Disable tracing of data. If there is still data left in the shift register, it will be shifted out before disabling the shift operations. The data captured in the FIFO remains there until the ON/OFF bits are set to Ah. |
|     |         |            | <b>NOTE:</b> It is recommended to write 5h to disable the module to prevent a soft error from enabling the module inadvertently by a single bit flip.                                                                      |
|     |         |            |                                                                                                                                                                                                                            |

**Table 31-8. FIFO Corresponding Addresses**

| FIFO | Address    |
|------|------------|
| 1    | FFF8 3000h |
| 2    | FFF8 3400h |
| 4    | FFF8 3C00h |

**Table 31-9. Pins Used for Data Communication**

| Port Width (PW) | Pins Used     |
|-----------------|---------------|
| 00              | RTPDATA[1:0]  |
| 01              | RTPDATA[3:0]  |
| 10              | RTPDATA[7:0]  |
| 11              | RTPDATA[15:0] |

### 31.4.2 RTP Trace Enable Register (RTPTRENA)

This register enables/disables tracing of the different RAM blocks or the peripherals individually. [Figure 31-10](#) and [Table 31-10](#) illustrate this register.

**Figure 31-10. RTP Trace Enable Register (RTPTRENA) [offset = 04h]**

**Table 31-10. RTP Trace Enable Register (RTPTRENA) Field Descriptions**

| Bit   | Field    | Value | Description                                                                                                                                                                                                                                                                                                                         |
|-------|----------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-25 | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                              |
| 24    | ENA4     | 0     | Enable tracing for peripherals. This bit enables tracing into FIFO4 in trace mode (read/write) or direct data mode (read) operations. In Direct Data Mode write operations, this bit will be ignored and tracing into FIFO4 will be disabled.<br>User and privilege mode (read):<br>0 Tracing is disabled.<br>1 Tracing is enabled. |
|       |          | 0     | Privilege mode (write):<br>0 Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO4 will still be transmitted ( <a href="#">Section 31.4.1</a> ).<br>1 Enable tracing.                                                                                                                                          |
| 23-9  | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                              |
| 8     | ENA2     | 0     | Enable tracing for RAM block 2. This bit enables tracing into FIFO2 in Trace Mode (read/write) or Direct Data Mode (read) operations. In Direct Data Mode write operations, this bit will be ignored and tracing into FIFO2 will be disabled.<br>User and privilege mode (read):<br>0 Tracing is disabled.<br>1 Tracing is enabled. |
|       |          | 0     | Privilege mode (write):<br>0 Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO2 will still be transmitted.<br>1 Enable tracing.                                                                                                                                                                             |
| 7-1   | Reserved | 0     | Read returns 0. Writes have no effect.                                                                                                                                                                                                                                                                                              |
| 0     | ENA1     | 0     | Enable tracing for RAM block 1. This bit enables tracing into FIFO1 in Trace Mode (read/write) or Direct Data Mode (read) operations. In Direct Data Mode write operations, this bit will be ignored and tracing into FIFO1 will be disabled.<br>User and privilege mode (read):<br>0 Tracing is disabled.<br>1 Tracing is enabled. |
|       |          | 0     | Privilege mode (write):<br>0 Disable tracing. If RTPGLBCTRL.ON/OFF = Ah, data already captured in FIFO1 will still be transmitted.<br>1 Enable tracing.                                                                                                                                                                             |

### 31.4.3 RTP Global Status Register (RTPGSR)

This register provides status information of the module. [Figure 31-11](#) and [Table 31-11](#) illustrate this register.

| 17-0  | STARTADDR | 0-3 FFFFh                                                                         | These bits define the starting address of the address region that should be traced. The start address has to be a multiple of the block size chosen. If the start address is not a multiple of the block size, the start of the region will begin at the next lower block size boundary.                                                                                                                                                                                                                                                                                                                                                               |

### 31.4.6 RTP Peripheral Trace Region [1:2] Registers (RTPPERREG[1:2])

FIFO4 is dedicated for tracing the peripheral accesses. Since the peripheral frame is 16 Mbytes, the start address has to be defined as a 24-bit value. However, only bits 16 to 0 will be transmitted in the protocol. Bit REG (Section 31.2.1.1) in the protocol will be 0 if there was an access to the range defined by RTPPERREG1. REG will be 1 if the access was into the range defined by RTPPERREG2. Figure 31-14 and Table 31-14 illustrate these registers.

The start address has to be a multiple of the block size chosen. If the start address is not a multiple of the block size, the start of the region will begin at the next lower block size boundary.                                                                                                                                                                                                                                                    |

### 31.4.7 RTP Direct Data Mode Write Register (RTPDDMW)

The CPU has to write data to this register if the module is used in Direct Data Mode write configuration. [Figure 31-15](#) and [Table 31-15](#) illustrate this register.

**Figure 31-15. RTP Direct Data Mode Write Register (RTPDDMW) [offset = 2Ch]**

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 31-15. RTP Direct Data Mode Write Register (RTPDDMW) Field Descriptions**

| Bit  | Field | Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|-------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0 | DATA  | 0-FFFF FFFFh | This register must be written to in a Direct Data Mode write operation to store the data into FIFO1. Data written must be right-aligned. If the FIFO is full, the reaction depends on the setting of the HOVF bit ( <a href="#">Section 31.4.1</a> ). If the bit is set, the master writing the data will be wait-stated. If the bit is cleared, previous data written to the register will be overwritten.<br>Reads of this register always return 0. |

### 31.4.8 RTP Pin Control 0 Register (RTPPC0)

This register configures the RTP pins as functional or GIO pins. Once the pin is configured in functional mode, it overrides the settings in the [RTPPC1](#) register. Writing to [RTPPC3](#), [RTPPC4](#) and [RTPPC5](#) will have no effect for pins configured as functional pins. [Figure 31-16](#) and [Table 31-16](#) illustrate this register.

**Figure 31-16. RTP Pin Control 0 Register (RTPPC0) [offset = 34h]**

### 31.4.9 RTP Pin Control 1 Register (RTPPC1)

Once the pin is configured in functional mode (RTPPC0, [Section 31.4.8](#)), configuring the corresponding bit in RTPPC1 to 0 will not disable the output driver. [Figure 31-17](#) and [Table 31-17](#) illustrate this register.

**Figure 31-17. RTP Pin Control 1 Register (RTPPC1) [offset = 38h]**

### 31.4.11 RTP Pin Control 3 Register (RTPPC3)

The bits in this register define the state of the pins when configured in GIO mode as output pins. Once a pin is configured in functional mode ([RTPPC0](#)), changing the state of the corresponding bit in RTPPC3 will not affect the pin's state. [Figure 31-19](#) and [Table 31-19](#) illustrate this register.

**Figure 31-19. RTP Pin Control 3 Register (RTPPC3) [offset = 40h]**

|       |            | 1     | Set pin to logic high (1) (output voltage is $V_{OH}$ or higher).                                                                                                                                                                                        |

### 31.4.12 RTP Pin Control 4 Register (RTPPC4)

This register provides the option to set pins to a logic 1 level without influencing the state of other pins. It eliminates the read-modify-write operation necessary with [RTPPC3](#). Once the pin is configured in functional mode ([RTPPC0](#)), setting the corresponding bit to one in RTPPC4 will not affect the pin's state. [Figure 31-20](#) and [Table 31-20](#) illustrate this register.

**Figure 31-20. RTP Pin Control 4 Register (RTPPC4) [offset = 44h]**

|       |            | 1     | Set pin to logic low (0) (output voltage is V <sub>OL</sub> or lower).                                                                                                                                                              |

### 31.4.14 RTP Pin Control 6 Register (RTPPC6)

These bits configure the pins in push-pull or open-drain functionality. If configured to be open-drain, the module only drives a logic low level on the pin. An external pull-up resistor needs to be connected to the pin to pull it high when the pin is in high-impedance mode. [Figure 31-22](#) and [Table 31-22](#) illustrate this register.

**Figure 31-22. RTP Pin Control 6 Register (RTPPC6) [offset = 4Ch]**

| Bit  | Field      | Value | Description                                                                                                                                                                                                                                                                                                             |
|------|------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0 | DATAPDR[n] |       | <b>RTPDATA[15:0] Open drain enable.</b> These bits enable open-drain functionality on the pins, if they are configured as GPIO output (RTPPC0[15:0]=0; RTPPC1[15:0]=1). If the pins are configured as functional pins (RTPPC0[15:0]=1), the open-drain functionality is disabled. Each bit [n] represents a single pin. |
|      |            |       | User and privilege mode (read):                                                                                                                                                                                                                                                                                         |
|      |            | 0     | Pin behaves as normal push/pull pin.                                                                                                                                                                                                                                                                                    |
|      |            | 1     | Pin operates in open drain mode.                                                                                                                                                                                                                                                                                        |
|      |            |       | User and privilege mode (write):                                                                                                                                                                                                                                                                                        |
|      |            | 0     | Configures the pin as push/pull.                                                                                                                                                                                                                                                                                        |
|      |            | 1     | Configures the pin as open drain.                                                                                                                                                                                                                                                                                       |

### 31.4.15 RTP Pin Control 7 Register (RTPPC7)

The bits in register control the pullup/down functionality of a pin. The internal pullup/down can be enabled or disabled by this register. The reset configuration of these bits is device implementation dependent. Please consult the device datasheet this information. [Figure 31-23](#) and [Table 31-23](#) illustrate this register.

**Figure 31-23. RTP Pin Control 7 Register (RTPPC7) [offset = 50h]**

|       |             | 1     | Pullup functionality is enabled.                                                                                                                  |
| 15-0  | DATAPSEL[n] |       | User and privilege mode (write):                                                                                                                  |
|       |             | 0     | Enables pulldown functionality.                                                                                                                   |
|       |             | 1     | Enables pullup functionality.                                                                                                                     |
|       |             |       | <b>RTPDATA[15:0] Pull select.</b> These bits configure pullup or pulldown functionality, if RTPPC7[15:0]=0. Each bit [n] represents a single pin. |
|       |             | 0     | User and privilege mode (read):<br>Pulldown functionality is enabled.                                                                             |
|       |             | 1     | Pullup functionality is enabled.                                                                                                                  |
|       |             |       | User and privilege mode (write):                                                                                                                  |
|       |             | 0     | Enables pulldown functionality.                                                                                                                   |
|       |             | 1     | Enables pullup functionality.                                                                                                                     |

## ***eFuse Controller***

This chapter describes the eFuse controller.

| Topic                                        | Page        |
|----------------------------------------------|-------------|
| <b>32.1 Overview.....</b>                    | <b>1735</b> |
| <b>32.2 Introduction .....</b>               | <b>1735</b> |
| <b>32.3 eFuse Controller Testing .....</b>   | <b>1735</b> |
| <b>32.4 eFuse Controller Registers .....</b> | <b>1738</b> |

## 32.1 Overview

Electrically programmable fuses (eFuses) are used to configure the device after deassertion of  $\overline{\text{PORRST}}$ . The eFuse values are read and loaded into internal registers as part of the power-on-reset sequence. The eFuse values are protected with single bit error correction, double bit error detection (SECDED) codes. These fuses are programmed during the initial factory test of the device. The eFuse controller is designed so that the state of the eFuses cannot be changed once the device is packaged.

## 32.2 Introduction

The eFuse controller automatically reads the values of the eFuses and shifts them into registers during the power-on reset sequence. No action is required from the application code. However, in a safety critical application, the user code should check to see if a correctable or an uncorrectable error was detected during the reset sequence and then preform a self-test on the eFuse controller ECC logic.

## 32.3 eFuse Controller Testing

### 32.3.1 eFuse Controller Connections to ESM

There are three connections from the eFuse controller to the Error Signaling Module (ESM). If an uncorrectable error occurs during the loading of the eFuse values after reset, a group three, channel one error and a group one channel 40 error are sent to the ESM. The group three error will cause the  $\overline{\text{ERROR}}$  pin to go low. If during the eFuse loading a correctable error occurs, only a group one channel 40 error is sent to the ESM. If an error occurs during the eFuse controller self test, then a group one channel 41 error and a group one channel 40 error are sent to the ESM. After reset, by default, the group one errors do not affect the  $\overline{\text{ERROR}}$  pin. If the software enables the appropriate bit in the appropriate ESM Influence Error Pin Set/Status Register (ESMIEPSRn) while the group one error is set, the  $\overline{\text{ERROR}}$  pin will go low.

**Table 32-1. ESM Signals Set by eFuse Controller**

| ESM Signal         | Uncorrected Load Failure | Correctable Load Error | Self Test       |                              |                                 |
|--------------------|--------------------------|------------------------|-----------------|------------------------------|---------------------------------|
|                    |                          |                        | eFuse Self Test | eFuse stuck at 0 Test        |                                 |
|                    |                          |                        |                 | Version a:<br>with Error pin | Version b:<br>without Error pin |
| Group 3 Channel 1  | X                        |                        |                 | X                            |                                 |
| Group 1 Channel 40 | X                        | X                      | X               |                              |                                 |
| Group 1 Channel 41 |                          |                        | X               | X                            | X                               |

### 32.3.2 Checking for eFuse Errors After Power Up

For safety critical systems, it is required that you check the status of the eFuse controller after a device reset. A suggested flow chart for checking the eFuse controller after device reset is shown in [Figure 32-1](#). Failures during the eFuse self test can be grouped into three levels of severity. Depending on the safety critical application, the error handling for each error type may be different.

#### 32.3.2.1 Class 1 Error

A class 1 error of the eFuse controller means that there was a failure during the autoloading sequence. The values read from the eFuses cannot be relied on. All device operation is suspect. A class 1 error is indicated by a signal to group 3 channel 1 of the ESM. This will cause the  $\overline{\text{ERROR}}$  pin to go active low.

#### 32.3.2.2 Class 2 Errors

A class 2 error is an indication that the safety checks of the eFuse controller did not work. These are also serious errors because you can no longer guarantee that a more severe error did not occur.

### 32.3.2.3 Class 3 Error

A class 3 error indicates that there was a single bit failure reading the eFuses that was corrected by ECC bits. Proper operation is still likely, but the system is now at a higher risk for a future non-correctable error. When a correctable error occurs, ESM group 1, channel 40 will be set. In the suggested flow chart shown in [Figure 32-1](#) below, the single bit error is determined by directly reading the eFuse error status register, and not depending on the integrity of the connections between the eFuse controller and the ESM.

### 32.3.2.4 Stuck at Zero Test

The purpose of the stuck at zero test is to verify that the eFuse controller could signal the ESM if an autoload error did occur. It basically verifies the path through the eFuse controller and to the ESM. This is done by writing a special instruction to the eFuse controller boundary register, then verifying that the proper bits are set in the eFuse controller pins register. Upon successful completion of this test ESM group 1 channel 41 and ESM group 3 channel 1 will be set. This will force the **ERROR** pin low.

- Version A
  - Write boundary register (address 0xFFFF8C01C) with 0x003FC000 to set the error signals.
  - Read pins register (address 0xFFFF8C02C) and verify that bits 14, 12, 11 and 10 are set.
  - Write boundary register (address 0xFFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 and group 3 channel 1 are set, then clear them.

If the system cannot support a test which causes the **ERROR** pin to go low, then the stuck at zero test can be modified as follows:

- Version B
  - Write boundary register (address 0xFFFF8C01C) with 0x003BC000.
  - Read pins register (address 0xFFFF8C02C) and verify that bits 14, 12, and 11 are set.
  - Write boundary register (address 0xFFFF8C01C) with 0x003C0000, to clear the error signals.
  - Verify that ESM group 1 channel 41 is set, then clear it.

This alternate method provides less test coverage because the path from the uncorrectable error signal from the eFuse controller to the ESM is not specifically tested. However, even if this path is broken, reading the five eFuse error status bits will indicate that an error occurred.

### 32.3.2.5 eFuse ECC Logic Self Test

The eFuse controller self test performs extensive validation of the ECC logic in the eFuse controller. This test should only be performed once for every device **PORRST** cycle. Perform the self test by following these steps:

- Write 0x00000258 to the self test cycles register (EFCSTCY) at address 0xFFFF8C048.
- Write 0x5362F97F to the self test signature register (EFCSTSIG) at address 0xFFFF8C04C.
- Write 0x0000200F to the boundary register at address 0xFFFF8C01C. This triggers the self test. The test takes 610 VCLK cycles to complete. The application can poll bit 15 of the pins register at address 0xFFFF8C02C to wait for the test to complete.
- Check ESM group 1 channels 40 and 41 for any errors, neither should be set.
- Verify that bits 4 to 0 of the eFuse Error Status register at address 0xFFFF8C03C are zero.

Figure 32-1. eFuse Self Test Flow Chart

## 32.4 eFuse Controller Registers

All registers in the eFuse Controller module are 32-bit, word-aligned; 8-bit, 16-bit and 32-bit accesses are allowed. [Table 32-2](#) provides a quick reference to each of these registers. Specific bit descriptions are discussed in the following subsections. The base address for the control registers is FFF8 C000h.

**Table 32-2. eFuse Controller Registers**

| Offset | Acronym    | Register Description             | Section                        |
|--------|------------|----------------------------------|--------------------------------|
| 1Ch    | EFCBOUND   | EFC Boundary Control Register    | <a href="#">Section 32.4.1</a> |
| 2Ch    | EFCPINS    | EFC Pins Register                | <a href="#">Section 32.4.2</a> |
| 3Ch    | EFCERRSTAT | EFC Error Status Register        | <a href="#">Section 32.4.3</a> |
| 48h    | EFCSTCY    | EFC Self Test Cycles Register    | <a href="#">Section 32.4.4</a> |
| 4Ch    | EFCSTSIG   | EFC Self Test Signature Register | <a href="#">Section 32.4.5</a> |

### 32.4.1 EFC Boundary Control Register (EFCBOUND)

[Figure 32-2](#) and [Table 32-3](#) describe the EFCBOUND register. The eFuse Boundary Control Register is used to test the connections between the eFuse controller and the ESM module. The eFuse Boundary Control Register is also used to initiate an eFuse controller ECC self-test.

**Figure 32-2. EFC Boundary Control Register (EFCBOUND) [offset = 1Ch]**

The EDAC circuitry might have a fault.<br>All other values are reserved for e-fuse system tests and are not expected to occur in normal system use. |

### 32.4.4 EFC Self Test Cycles Register (EFCSTCY)

Figure 32-5 and Table 32-6 describe the EFCSTCY register.

**Figure 32-5. EFC Self Test Cycles Register (EFCSTCY) [offset = 48h]**

|        |  |  |  |  |  |  |    |
|--------|--|--|--|--|--|--|----|
| 31     |  |  |  |  |  |  | 16 |
| Cycles |  |  |  |  |  |  |    |
| R/W-0  |  |  |  |  |  |  |    |
| 15     |  |  |  |  |  |  | 0  |
| Cycles |  |  |  |  |  |  |    |
| R/W-0  |  |  |  |  |  |  |    |

LEGEND: R/W = Read/Write; -n = value after power-on reset (nPORRST)

**Table 32-6. EFC Self Test Cycles Register (EFCSTCY) Field Descriptions**

| Bit  | Name   | Description                                                                                                                                                    |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Cycles | This register is used to determine the number of cycles to run the eFuse controller ECC logic self test. It is recommended to use a value of 600 (0x00000258). |

### 32.4.5 EFC Self Test Signature Register (EFCSTSIG)

Figure 32-6 and Table 32-7 describe the EFCSTSIG register.

**Figure 32-6. EFC Self Test Cycles Register (EFCSTSIG) [offset = 4Ch]**

LEGEND: R/W = Read/Write; -n = value after power-on reset (nPORRST)

**Table 32-7. EFC Self Test Cycles Register (EFCSTSIG) Field Descriptions**

| Bit  | Name      | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Signature | This register is used to hold the expected signature for the eFuse ECC logic self test. It is recommended to write a value of 0x5362F97F to this register and a value of 600 (0x00000258) to the EFCSTCY register. If after running the eFuse ECC logic self test, the calculated signature does not match the expected signature in the EFCSTSIG register, then a value of 18h is stored in the EFCERRSTAT register. |

## Revision History

| Changes from August 3, 2013 to February 28, 2018                                                                                         | Page |
|------------------------------------------------------------------------------------------------------------------------------------------|------|
| • <b>Chapter 1: Introduction</b> .....                                                                                                   | 89   |
| • <b>Figure 1-1:</b> Added MIBSPI5_CLK signal .....                                                                                      | 92   |
| • <b>Figure 1-1:</b> Deleted EMIF_RnW signal .....                                                                                       | 92   |
| • <b>Chapter 2: Architecture</b> .....                                                                                                   | 94   |
| • <b>Table 2-1:</b> Rearranged sequence of terms. Added USB .....                                                                        | 96   |
| • <b>Table 2-2:</b> Changed table. Added Access Mode column.....                                                                         | 98   |
| • <b>Section 2.2.3.2:</b> In fourth paragraph, corrected starting address of bank 7 ECC from 0xF0200000 to 0xF010 0000 ....              | 105  |
| • <b>Table 2-5:</b> Added USB.....                                                                                                       | 106  |
| • <b>Table 2-6:</b> Changed table. Corrected values in Valid RAM Groups and Valid RINFO Register Value columns .....                     | 107  |
| • <b>Table 2-7:</b> Changed NHET2 RAM Address Range End to 0xFF45FFFF .....                                                              | 110  |
| • <b>Table 2-7:</b> Added USB and Ethernet RAM (CPPI Memory Slave) .....                                                                 | 110  |
| • <b>Table 2-7:</b> Deleted table footnote (3). Subsequent footnotes renumbered .....                                                    | 110  |
| • <b>Section 2.3.1:</b> Updated third sentence in second paragraph. Changed to minimum of 32 peripheral clock (VCLK) cycles .....        | 111  |
| • <b>Table 2-8:</b> Updated Description of Debug reset. Changed DBG_RST bit to WDRST bit .....                                           | 111  |
| • <b>Table 2-8:</b> Updated Description of Watchdog reset .....                                                                          | 111  |
| • <b>Table 2-9:</b> Changed Description of LF LPO and HF LPO .....                                                                       | 114  |
| • <b>Table 2-10:</b> Changed VCLKA3_S to VCLKA3.....                                                                                     | 115  |
| • <b>Table 2-10:</b> Changed Special Considerations description of VCLKA3_DIVR. Changed VCLKA3_S to VCLKA3.....                          | 115  |
| • <b>Figure 2-4:</b> Added SEL_GPIO_PIN field to CLKTEST register .....                                                                  | 119  |
| • <b>Table 2-12:</b> Changed signals on ECLK .....                                                                                       | 119  |
| • <b>Section 2.4.5:</b> Added Embedded Trace Macrocell (ETM-R4) subsection. Subsequent subsections, figures, and tables renumbered ..... | 120  |
| • <b>Section 2.5.1:</b> Updated paragraph .....                                                                                          | 123  |
| • <b>Table 2-31:</b> Changed Description of bits for Value = 0 (Read) to enabled .....                                                   | 132  |
| • <b>Section 2.5.1.13:</b> Added second paragraph to NOTE .....                                                                          | 133  |
| • <b>Figure 2-18:</b> Changed bit 5 to Reserved .....                                                                                    | 133  |
| • <b>Table 2-32:</b> Changed bit 5 to Reserved .....                                                                                     | 133  |
| • <b>Figure 2-19:</b> Corrected register bit name for bits 4, 3, 2, 1, and 0.....                                                        | 135  |
| • <b>Figure 2-19:</b> Changed bit 5 to Reserved .....                                                                                    | 135  |
| • <b>Table 2-33:</b> Changed bit 5 to Reserved .....                                                                                     | 135  |
| • <b>Figure 2-20:</b> Changed bit 5 to Reserved .....                                                                                    | 136  |
| • <b>Table 2-34:</b> Changed bit 5 to Reserved .....                                                                                     | 136  |
| • <b>Table 2-35:</b> Changed Description of GHVSR bit. Removed "on wakeup" .....                                                         | 138  |
| • <b>Figure 2-22:</b> Changed bits 11-8 to Reserved.....                                                                                 | 139  |
| • <b>Table 2-36:</b> Changed bits 11-8 to Reserved.....                                                                                  | 139  |
| • <b>Table 2-41:</b> Updated MSTGENA and MINITGENA values to Ah for MSIENA = 1 .....                                                     | 144  |
| • <b>Table 2-44:</b> Corrected Description of PLLMUL bit. Value = 0h is ×1, Value = 100h is ×2 .....                                     | 147  |
| • <b>Figure 2-33:</b> Corrected register bit fields .....                                                                                | 150  |
| • <b>Table 2-47:</b> Changed table to reflect updated register bit fields .....                                                          | 150  |
| • <b>Figure 2-34:</b> Corrected register bit fields .....                                                                                | 150  |
| • <b>Table 2-48:</b> Changed table to reflect updated register bit fields .....                                                          | 150  |
| • <b>Table 2-49:</b> Changed Description of OSCFRQCONFIGCNT bit. Writes have no effect.....                                              | 151  |
| • <b>Table 2-50:</b> Changed Description of SEL_GPIO_PIN and SEL_ECP_PIN bits. Changed VCLKA3_S to VCLKA3 .....                          | 154  |
| • <b>Figure 2-37:</b> Updated reset value of DFTWRITE and DFTREAD bits to 2h.....                                                        | 156  |
| • <b>Figure 2-39:</b> Corrected register bit name for bits 19-16 .....                                                                   | 158  |
| • <b>Table 2-53:</b> Changed Description of PLL1_FBSLIP_FILTER_COUNT and PLL1_FBSLIP_FILTER_KEY bits.....                                | 158  |
| • <b>Section 2.5.1.43:</b> Changed paragraph.....                                                                                        | 166  |
| • <b>Section 2.5.1.43:</b> Added NOTE.....                                                                                               | 166  |

|                                                                                                                                                |     |
|------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| • <a href="#">Section 2.5.1.44</a> : Changed NOTE .....                                                                                        | 167 |
| • <a href="#">Table 2-63</a> : Added Note to VCLK2R and VCLKR bits .....                                                                       | 167 |
| • <a href="#">Table 2-64</a> : Deleted Note from the ECPDIV bit .....                                                                          | 168 |
| • <a href="#">Section 2.5.1.47</a> : Added NOTE.....                                                                                           | 169 |
| • <a href="#">Section 2.5.1.48</a> : Updated paragraph. (Clarified description of how system exception status bits behave through reset) ..... | 170 |
| • <a href="#">Figure 2-53</a> : Updated Read/Write value of bits 14, 13, 5, 4, and 3 to R/WC-X* .....                                          | 170 |
| • <a href="#">Figure 2-53</a> : Changed Reserved bits to 2-0 .....                                                                             | 170 |
| • <a href="#">Figure 2-53</a> : Deleted MPMODE bit .....                                                                                       | 170 |
| • <a href="#">Table 2-67</a> : Changed Description of PORST and EXTRST bits .....                                                              | 170 |
| • <a href="#">Table 2-67</a> : Changed Description of WDRST bit. Added (DBGRST) .....                                                          | 170 |
| • <a href="#">Table 2-67</a> : Changed Reserved bits to 2-0 .....                                                                              | 170 |
| • <a href="#">Table 2-67</a> : Deleted MPMODE bit .....                                                                                        | 170 |
| • <a href="#">Figure 2-55</a> : Updated Read/Write value of FBSLIP, RFSLIP, and OSCFAIL bits to R/W1C-n .....                                  | 172 |
| • <a href="#">Figure 2-55</a> : Changed LEGEND .....                                                                                           | 172 |

| • Section 22.5.6: Added second sentence .....                                                                            | 1034 |
| • Figure 22-12: Updated Read/Write value of bits to R/W1C-0 .....                                                        | 1034 |
| • Figure 22-12: Updated LEGEND to include W1C .....                                                                      | 1034 |
| • Table 22-22: Changed Pull Control = Enabled when device is under reset .....                                           | 1043 |
| • <b>Chapter 23: Controller Area Network (DCAN) Module</b> .....                                                         | 1044 |
| • Equation 33: Corrected maximum tolerance of equation for condition I .....                                             | 1049 |
| • Equation 34: Updated equation .....                                                                                    | 1051 |
| • Equation 35: Updated equation .....                                                                                    | 1051 |
| • Section 23.3.2.3: Changed $t_q = 1 \mu s$ .....                                                                        | 1051 |
| • Equation 36: Updated equation .....                                                                                    | 1051 |
| • Equation 37: Updated equation .....                                                                                    | 1051 |
| • Table 23-2: Updated Description of DLC, Value = 0-8: Data Frame has 0-8 data bytes .....                               | 1054 |
| • Section 23.5.2: Changed first paragraph in NOTE. Added: At address 0x0000, message object number 64 is located .....   | 1056 |
| • Section 23.16: Changed subsection .....                                                                                | 1079 |
| • Section 23.17: Updated first paragraph to include base addresses .....                                                 | 1079 |
| • Table 23-6: Added Core Release Register .....                                                                          | 1079 |
| • Figure 23-20: Updated Read/Write value of PER bit to R/C-0 .....                                                       | 1083 |
| • Table 23-9: Updated Description of REC bit (Values from 0 to 127) .....                                                | 1085 |
| • Table 23-11: Corrected Value column range of Int1ID and Int0ID bits to 1h-40h .....                                    | 1087 |
| • Table 23-13: Corrected Value column range of Message Number bit to 1h-FFh .....                                        | 1089 |
| • Table 23-13: Updated Description of Message Number bit. Only values 1h-40h are valid. Values 41h-FFh are invalid ..... | 1089 |
| • Section 23.17.8: Added subsection. Subsequent subsections, figures, and tables renumbered .....                        | 1089 |
| • Figure 23-27: Corrected register bit name to ABO_TIME .....                                                            | 1090 |
| • Table 23-15: Corrected register bit name to ABO_TIME .....                                                             | 1090 |
| • Table 23-21: Corrected Value column range of Message Number bit to 1h-40h .....                                        | 1100 |
| • Table 23-24: Updated Description of EoB bit .....                                                                      | 1105 |
| • Section 23.17.24: Changed sixth paragraph .....                                                                        | 1107 |
| • Section 23.17.30: Changed first paragraph in NOTE. Writable only if Init bit of CAN Control Register is set .....      | 1114 |
| • Section 23.17.31: Changed first paragraph in NOTE. Writable only if Init bit of CAN Control Register is set .....      | 1115 |
| • Table 23-31: Changed the Func Bit description for Value = 1. (as an input to receive CAN data) .....                   | 1115 |
| • <b>Chapter 24: Multi-Buffered Serial Peripheral Interface Module (MibSPI) with Parallel Pin Option (MibSPIP)</b> ....  | 1117 |
| • Chapter 24: Global: Changed SPISCS to SPICS .....                                                                      | 1117 |
| • Section 24.1: Changed third and seventh bullets in second paragraph .....                                              | 1118 |
| • Section 24.2: Changed first sentence in second paragraph .....                                                         | 1119 |
| • Section 24.2: Added NOTE .....                                                                                         | 1119 |
| • Table 24-1: Changed SPIENA enabled description in Slave Mode .....                                                     | 1120 |
| • Figure 24-6: Corrected figure title .....                                                                              | 1126 |
| • Figure 24-6: Corrected bits D11-D8 to 1110 .....                                                                       | 1126 |
| • Figure 24-7: Corrected figure title .....                                                                              | 1126 |
| • Section 24.2.9: Updated first two paragraphs .....                                                                     | 1130 |
| • Section 24.2.11.2: Added subsection The CSHOLD Bit in Slave Mode (Multi-buffered Mode) .....                           | 1131 |
| • Section 24.2.12: Changed sixth sentence. Added T2EDELAY .....                                                          | 1131 |
| • Section 24.2.13: Changed second sentence. Added C2EDELAY .....                                                         | 1132 |
| • Section 24.8.1: Changed second sentence .....                                                                          | 1146 |
| • Section 24.8.1: Changed second sentence .....                                                                          | 1147 |
| • Section 24.9: Updated paragraph to include base addresses .....                                                        | 1148 |
| • Section 24.9: Global: Updated all VBUSPCLK signals to VCLK .....                                                       | 1148 |

|                                                                                                                                                                      |      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| • <a href="#">Table 24-7</a> : Added SPIPC9 at address offset 68h .....                                                                                              | 1148 |
| • <a href="#">Table 24-9</a> : Updated second bullet in Description of SPIEN bit. Added SPIDAT0 and SPIDAT1 .....                                                    | 1150 |
| • <a href="#">Table 24-9</a> : Changed Description of CLKMOD bit for Value = 1. (SPIEN $\overline{A}$ is an input.) .....                                            | 1150 |
| • <a href="#">Figure 24-30</a> : Updated Read/Write value of RXINTFLG, RXOVRNINTFLG, BITERRFLG, DESYNCFLG, PARERRFLG, TIMEOUTFLG, and DLENERRFLG bits to R/W1C ..... | 1154 |
| • <a href="#">Figure 24-30</a> : Updated LEGEND to include W1C .....                                                                                                 | 1154 |
| • <a href="#">Table 24-12</a> : Corrected bit 2 name to PARERRFLG .....                                                                                              | 1154 |
| • <a href="#">Table 24-14</a> : Corrected Description of SIMODIR0 bit .....                                                                                          | 1158 |
| • <a href="#">Table 24-20</a> : Updated Description of all bits to clarify that bit is a pull control disable .....                                                  | 1167 |
| • <a href="#">Table 24-21</a> : Updated Description of CLKPSEL, ENAPSEL, and SCSPSEL bits. 1 = Pull up .....                                                         | 1168 |
| • <a href="#">Table 24-22</a> : Changed Description of TXDATA bit. Added last Note .....                                                                             | 1170 |
| • <a href="#">Section 24.9.16</a> : Added NOTE .....                                                                                                                 | 1171 |
| • <a href="#">Table 24-23</a> : Updated Description of CSNR and TXDATA bits .....                                                                                    | 1171 |
| • <a href="#">Table 24-24</a> : Added table. Subsequent tables renumbered .....                                                                                      | 1173 |
| • <a href="#">Table 24-25</a> : Corrected Description of RXEMPTY bit. (SPIBUF to RXDATA) .....                                                                       | 1174 |
| • <a href="#">Table 24-27</a> : Corrected Value column for all bits to 0-FFh .....                                                                                   | 1176 |
| • <a href="#">Table 24-27</a> : Updated Description of C2TDELAY bit. Deleted first NOTE .....                                                                        | 1176 |
| • <a href="#">Table 24-27</a> : Updated Description of T2CDELAY bit. Deleted first and third NOTE .....                                                              | 1176 |
| • <a href="#">Figure 24-49</a> : Updated reset value of CSDEF bit to FFh .....                                                                                       | 1179 |
| • <a href="#">Table 24-29</a> : Updated formula in Description of PRESCALE bit. (PRESCALE $\times$ + 1) .....                                                        | 1180 |
| • <a href="#">Section 24.9.24</a> : Added subsection. Subsequent subsections, figures, and tables renumbered .....                                                   | 1185 |
| • <a href="#">Table 24-35</a> : Updated bit Descriptions to clarify register bit number corresponding to TG number .....                                             | 1190 |
| • <a href="#">Table 24-36</a> : Updated bit Descriptions to clarify register bit number corresponding to TG number .....                                             | 1191 |
| • <a href="#">Table 24-36</a> : Changed Description of CLRINTENRDY and CLRINTENSUS bits for Value = 1 (Write). The interrupt does not get generated .....            | 1191 |
| • <a href="#">Table 24-37</a> : Updated bit Descriptions to clarify register bit number corresponding to TG number .....                                             | 1192 |
| • <a href="#">Table 24-38</a> : Updated bit Descriptions to clarify register bit number corresponding to TG number .....                                             | 1193 |
| • <a href="#">Table 24-38</a> : Changed Description of CLRINTLVLRDY and CLRINTLVLSUS bits for Value = 1 (Write). Clear the TGx interrupt INTO .....                  | 1193 |
| • <a href="#">Table 24-39</a> : Updated bit Descriptions to clarify register bit number corresponding to TG number .....                                             | 1194 |
| • <a href="#">Table 24-40</a> : Changed Description of TICKENA bit for Value = 1. Deleted second sentence .....                                                      | 1195 |
| • <a href="#">Table 24-40</a> : Corrected Value column of CLKCTRL bit .....                                                                                          | 1195 |
| • <a href="#">Table 24-41</a> : Changed Note in LPEND bit .....                                                                                                      | 1196 |
| • <a href="#">Table 24-43</a> : Updated Description of ONESHOT bit. Added Note .....                                                                                 | 1200 |
| • <a href="#">Table 24-43</a> : Updated Description of ICOUNTx bit. Added last sentence to second paragraph .....                                                    | 1200 |
| • <a href="#">Figure 24-73</a> : Updated Read/Write value of SCS_FAIL_FLG bit to R/W1C .....                                                                         | 1208 |
| • <a href="#">Figure 24-73</a> : Updated LEGEND to include W1C .....                                                                                                 | 1208 |
| • <a href="#">Figure 24-74</a> : Changed format .....                                                                                                                | 1210 |
| • <a href="#">Figure 24-75</a> : Changed format .....                                                                                                                | 1212 |

## IMPORTANT NOTICE FOR TI DESIGN INFORMATION AND RESOURCES

Texas Instruments Incorporated ("TI") technical, application or other design advice, services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using any particular TI Resource in any way, you (individually or, if you are acting on behalf of a company, your company) agree to use it solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources.

You understand and agree that you remain responsible for using your independent analysis, evaluation and judgment in designing your applications and that you have full and exclusive responsibility to assure the safety of your applications and compliance of your applications (and of all TI products used in or for your applications) with all applicable regulations, laws and other applicable requirements. You represent that, with respect to your applications, you have all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. You agree that prior to using or distributing any applications that include TI products, you will thoroughly test such applications and the functionality of such TI products as used in such applications. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

You are authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING TI RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY YOU AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

You agree to fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of your non-compliance with the terms and provisions of this Notice.

This Notice applies to TI Resources. Additional terms apply to the use and purchase of certain types of materials, TI products and services. These include; without limitation, TI's standard terms for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>), [evaluation modules](#), and [samples](http://www.ti.com/sc/docs/sampterm.htm) (<http://www.ti.com/sc/docs/sampterm.htm>).
