

## OCTAL POWER SOURCING EQUIPMENT POWER MANAGER

### FEATURES

- Compliant to Power Over Ethernet IEEE 802.3af Standard
- Octal Power Port Control
- Operation in DTE PSE or Stand-Alone Mid-Span Modes
- Two-Point 25-k $\Omega$  Resistor Discovery
- Capacitive Detection for Non-Compliant Legacy Loads
- Power Classification with Bypass Option
- Controlled di/dt Ramp Power-Up and Power-Down for EMI Reduction
- Current Management for Charging Powered Device Bulk Capacitance
- Electronic Circuit Breaker
- Fault detection
- Input Undervoltage Lockout (UVLO)
- Load Overcurrent and Undercurrent Detection
- 12-Bit Port Current and Voltage Acquisition
- Standard Slave I<sup>2</sup>C Serial Interface
- 5-Bit Serial Address Selectability
- Discovery and/or Classification Bypass Modes Selectable Via Register
- Opto-Coupler Compatible SDA and SCL Lines for System Ground Isolation
- Dual Color LED Driver for Port Status
- Hardware FAULT Interrupt
- Minimal, Per-Port External Parts Count
- Single +48-V Supply Capable
- 64-Pin LQFP Package (PM)

### DESCRIPTION

The TPS2383 family of products are power sourcing equipment power managers (PSEPM) that are compliant to the power-over-ethernet (PoE) IEEE 802.3af Standard. A PSEPM port can discover, classify and deliver power to a powered device (PD) capable of accepting PoE twisted pair cable. The TPS2383 is fully programmable by the user. This allows for the detection and powering of both fully compliant 802.3 devices as well as custom detection of legacy devices.

The TPS2383 PSEPM can individually manage power for up to eight ethernet ports. All operations of the TPS2383 are controlled through register read and write operations over a standard (slave) I<sup>2</sup>C serial interface. The TPS2383 has dual SDA lines to allow easy application of opto-coupler circuitry to maintain ethernet port isolation when a ground based controller is used. Each TPS2383 has five selection pins making it possible to address up to 32 devices on the I<sup>2</sup>C bus and allows individual control and monitoring of up to 256 ethernet ports from a single master I<sup>2</sup>C controller. Per-port write registers initiate and manipulate the flow of the discovery, classification, and power-up states while the read registers contain status information of the enable process, faults, classification value, and real time port operating current and voltage. Per-port status LED drivers are provided which can be manually controlled through the serial I/O.

The TPS2383 is available in a full function 64-pin LQFP.

**DESCRIPTION (continued)**

External N-channel MOSFETs switch port power. High-voltage (HV) gate drive ensures that these FETs are fully enhanced, resulting in lower power dissipation and enabling the use of lower costs FETs. The TPS2383 generates its HV gate supply from the 48-V port power, simplifying system power supply design. An external 3.3-V digital supply is also used. This supply can be active when 48-V power is not present which allows the user to access the part through the serial I/O in this case. A 5-V analog supply is used to power port LEDs and internal analog functions. Due to the very low quiescent current, both the 3.3-V and 5-V supply can be generated from the +48-V power bus with minimal external components. An internal power-on-reset (POR) circuit with an ORed external input pin resets all registers positions to a known safe state upon power up.

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

**ABSOLUTE MAXIMUM RATINGS**

over operating free-air temperature range unless otherwise noted<sup>(1)</sup>

		TPS2383	UNIT
Input voltage range, $V_{CC}$	V48, 1P, 2P, 3P, 4P, 5P, 6P, 7P, 8P, 1N, 2N, 3N, 4N, 5N, 6N, 7N, 8N	–0.5 to 65	V
	1RS, 2RS, 3RS, 4RS, 5RS, 6RS, 7RS, 8RS, 1G, 2G, 3G, 4G, 5G, 6G, 7G, 8G	–0.5 to 12	
	VL	–0.5 to 3.9	
	V5	–0.5 to 5	
	SCL_I, SDA_I, SDA_O, INTB, A1, A2, A3, A4, A5, EN, PORB	–0.5 to 6	
Storage temperature, $T_{stg}$		–55 to 150	°C
Operating temperature, $T_J$		0 to 70	
Lead temperature, $T_{sol}$ , 1.6 mm (1/16 inch) from case for 10 seconds		260	

(1) Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. All voltages are with respect to GND. Currents are positive into and negative out of, the specified terminal.

**RECOMMENDED OPERATING CONDITIONS**

	MIN	NOM	MAX	UNIT
Input voltage, $V_{V48}$	44	48	57	V
Operating junction temperature, $T_J$	0		70	°C

**ELECTROSTATIC DISCHARGE (ESD) PROTECTION**

	MAX	UNIT
Human body model	1.5	kV
CDM	1	
Machine model	0.2	

**ORDERING INFORMATION**

$T_A$	PACKAGED DEVICES <sup>(2)</sup>
	LQFP–64 (PM)
0°C to 70°C	TPS2383PM

(2) The PM package is available taped and reeled. Add R suffix to device type (e.g. TPS2383PMR) to order quantities of 2,500 devices per reel and 90 units per tube.

**ELECTRICAL CHARACTERISTICS**V<sub>V48</sub> = 48 V, R<sub>T</sub> = 120 kΩ, 0°C to 70°C, and T<sub>A</sub> = T<sub>J</sub> (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
POWER SUPPLIES

## TERMINAL FUNCTIONS

TERMINAL		I/O	DESCRIPTION
NAME	PIN		
POWER AND GROUND			
AG1	26	I	Analog ground 1. Analog ground of the V5, V10 and V48 power systems. It should be externally tied to the common copper 48-V return plane. This pin should carry the low side of two de-coupling capacitors tied to V48 and V10
AG2	51	I	Analog ground 2. Analog ground, which ties to the substrate and ESD of the device. It should be externally tied to the common copper 48-V return plane. AG1 and AG2 must be tied together directly for lowest noise operation.
DG	56	I	Digital ground. It connects to the internal logic ground bus. It should be externally tied to the common copper 48V return plane. In addition a 0.1uF de-coupling capacitor should terminate as close to this node and the VL pin as possible.
RG	29	I	Reference ground. A precision sense of the external ground plane. It should also be used as the ground guard ring for the integration capacitor (CINT). It should be the closest ground to the low side of the 0.5-Ω current sense resistors, as well as RD, CINT, and RT. It should tie to common copper 48-V return plane.
V10	28	O	+10V analog supply.Connects to the internal analog power bus. This voltage is generated internally. This pin should not be tied to any external supplies. A 0.1-μF de-coupling capacitor should terminate as close to this node and the AG2 pin as possible. This pin can be used for external generation of V5.
V48	27	I	+48V input to the device. This supply can have a range of 44 V to 57 V. This pin should be de-coupled with a 0.1-μF capacitor from V48 to AG2 placed as close to the device as possible.
V5	25	I	External +5V analog supply.Connects to the internal analog power bus. This supplies the LED output drivers and internal analog circuits. A 0.1-μF de-coupling capacitor should terminate as close to this node and the AG1 pin as possible.
VL	54	I	External +3.3V logic supply. This pin connects to the internal logic power bus. This is the supply voltage for the internal device logic. A 0.1-μF de-coupling capacitor should terminate as close to this node and the DG pin as possible. This pin can be powered from V5 by using a 4.22-kΩ resistor from V5 to VL..
PORT ANALOG SIGNALS			
1P	1	I	Port positive. +48V load sense pin. Terminal voltage is monitored and controlled differentially with respect to nN. Optionally, if the application warrants it, this high-side path can be protected with the use of a self-resetting poly fuse.
2P	8	I	
3P	9	I	
4P	16	I	
5P	33	I	
6P	40	I	
7P	41	I	
8P	48	I	
1N	2	I	Port negative. -48V load return sense pin. The low side of the load is switched and protected with the external N-channel MOSFET.
2N	7	I	
3N	10	I	
4N	15	I	
5N	34	I	
6N	39	I	
7N	42	I	
8N	47	I	

**TERMINAL FUNCTIONS (continued)**

TERMINAL		I/O	DESCRIPTION
NAME	PIN		
PORT ANALOG SIGNALS (continued)			
1G	3	O	Port gate. Connect to the gate of an external N-channel MOSFET. During turn-on, this pin is controlled by a linear current amplifier (LCA) such that the load current ramps up from zero to a maximum sourcing current of 425 mA. This pin is driven to as high as 10 V. During controlled turn-off, this pin is driven such that the load current ramps down from a maximum of 425 mA to zero. The capacitor on the CR pin is utilized to generate the ramp control signal voltages. During a fault turn-off this pin is discharged quickly with a low on-resistance internal switch.
2G	6	O	
3G	11	O	
4G	14	O	
5G	35	O	
6G	38	O	
7G	43	O	
8G	46	O	
1RS	4	I	Port resistor sense. This is the kelvin sense path for the high potential end of the load current sense resistor. <b>Parameters controlled by the load current sense resistor include: the average undercurrent/overcurrent and peak-load current thresholds, the peak PD inrush current limit during startup, and the nominal classification current levels.</b> Use a 0.5-Ω load current sense resistor to be compliant to the 802.3 specification levels.
2RS	5	I	
3RS	12	I	
4RS	13	I	
5RS	36	I	
6RS	37	I	
7RS	44	I	
8RS	45	I	
ANALOG SIGNALS			
CR	50	I	Ramp capacitor. During load power up and down, this capacitor is used as the di/dt current slew capacitor. A 4-V peak triangular waveform is present on this pin during ramp up/down. Connect a 0.047-μF capacitor from this pin to AG2 and a 120-kΩ resistor at RT to meet the 802.3af specification timing levels.
CT	52	I	Timing capacitor. This capacitor and the resistor on the RT pin set the internal clock frequency of the device. This clock is used for the internal state machine, integrating A/D counters, POR time-out, and fault and delay timers of each port. Use a 47-pF to 220-pF capacitor for CT and a 120-kΩ resistor on RT to set the internal clock in a range of 100 kHz to 500 kHz. This timing can be overridden by driving the CT pin with a 0 V to 5 V square wave with a frequency from 0 kHz to 500 kHz.
CINT	30	I	This capacitor is used for the ramp A/D converter signal integration. Connect a 0.033-μF capacitor from this pin to RG. For minimal errors due to dielectric absorption, use a poly or Teflon capacitor type. Ceramic types can be used, but note the increased conversion error.
L1	17	O	LED lamp drivers. Dual or single color LEDs can be connected to each of these pins. Each pin indicates the state of the corresponding port. This is a tri-state port that is under full control of the host micro-controller. As such it can also be used as a data port, or general-purpose output driver.
L2	18	O	
L3	19	O	
L4	20	O	
L5	21	O	
L6	22	O	
L7	23	O	
L8	24	O	
RD	32	I	The discovery current-sense resistor is connected in the path from the RD pin to RG ground. The discovery current-sense resistor sets the discovery value to 25-kΩ (nominal) when a 1000-Ω value is used. For best noise performance, de-couple this pin with a 0.82-μF, ceramic capacitor to RG ground.
RT	31	I	Bias set resistor. This resistor sets all precision bias currents within the device. This pin is forced to an internal 1.25-V reference voltage level. The current that flows into this resistor due to the applied 1.25-V bias is replicated and used throughout the device. This resistor also works in conjunction with the capacitors on CR, CT and CINT to set internal timing values. Use a 120-kΩ resistor to be compliant to the requirements of 802.3af.

**TERMINAL FUNCTIONS (continued)**

TERMINAL		I/O	DESCRIPTION
NAME	PIN		
DIGITAL SIGNALS			
A1	64	I	Addresses 1 through 5. This is the I <sup>2</sup> C address select input. Select the appropriate binary address on these pins by connecting this pin to device ground for a logic low and tying this pin to the VL pin for a logic high.
A2	63	I	
A3	62	I	
A4	61	I	
A5	60	I	
EN	53	I	This pin is normally to be held low. It has been reserved for future expansion of the TPS238x device family
INTB	59	O	This is an open drain output that goes low if a fault condition is produced on any of the eight ports.
PORB	49	I	This pin can be used to override the internal POR. When held low, the I <sup>2</sup> C interface, all the state machines, and registers are held in reset. When all internal and external supplies are within specification, and this pin is set to a logic high level, the POR delay begins. The I <sup>2</sup> C interface and registers becomes active within eight CLK periods of this event and communications to read or preset registers can begin. The reset delay for the remainder of the device then extinguishes within 65536 CLK periods.
SCL_I	55	I	Serial clock input pin for the I <sup>2</sup> C interface.
SDA_I	58	I	Serial data input pin for the I <sup>2</sup> C interface. When jumpered with the SDA_O pin, this connection becomes the standard bi-directional serial data line (SDA).
SDA_O	57	O	Serial data open drain output for the I <sup>2</sup> C interface. When jumpered with the SDA_I pin, this connection becomes the standard bi-directional serial data line (SDA). This is a high-voltage open drain output that can drive opto-coupler LEDs directly from the +48-V bus with an external, series current limiting resistor.

## FUNCTIONAL DESCRIPTION

The TPS2383 architecture has been designed to work efficiently with simple low-cost controllers such as those in the MSP430 family of devices. Reference design and code examples for complete PSE management are available from TI for the TPS2383/MSP430 chipset solution.

The PSEPM discovery method, as defined in the IEEE 802.3af Standard, uniquely identifies a powered device 25-k $\Omega$  – resistor. Use of low-level probe signals during discovery prevents damage to non-802.3 devices. The use of a point-to-point slope detection method for the PD 25-k $\Omega$  resistor measurement allows accurate detection, even if series steering diodes are present at the PD. For legacy loads, capacitive detection can be enabled. In this mode the TPS2383 A/D is used to measure the loads capacitive value.

After a successful discovery of the PD, the TPS2383 has a classification feature to identify the expected PD power level based on a current signature from the PD. The classification current level is measured at a reduced terminal voltage of 17.5 V and classified with 12 bits of resolution. The controller can then use this information to classify per the levels of the IEEE 802.3af standard or use levels custom to the application. Knowledge of the expected load power allows the power sourcing equipment to be built with a smaller and less expensive system power supply. For installations where classification is not needed, and reduced power-up time is desired, classification can be bypassed by setting the appropriate bits in the per-port write register.

In classification and powered modes, the PSEPM drives an external low side N-channel MOSFET for control of the 48-V return line. The use of an external N-channel MOSFET enables selection of very low  $R_{DS(on)}$  devices to minimize board power dissipation in enclosures that may be controlling 100's of ports. Current sensing is performed with a low value resistor, again minimizing board power dissipation. In discovery mode, due to the very low current used, an internal N-channel MOSFET is utilized in conjunction with an external, high value, current sense resistor.

The TPS2383 identifies all fault conditions defined in the PoE IEEE 802.3af Standard. The monitored conditions include input undervoltage lockout (UVLO), output undervoltage (UV) and overvoltage (OV), average and peak overcurrent detection, average undercurrent detection, and run current. If a fault condition is detected during power ramp or at any other time, the PSEPM circuit breaks by disconnecting the 48-V return line and then updates the fault status of the corresponding port register. When the TPS2383 is disabled the PSEPM ramps the current down at a controlled rate and the PSEPM changes states to a lower power sleep mode.

To maintain full compliance to Underwriters Laboratory (UL), IEC950 SELV and NEMKO safety standards an optional, low cost self-resetting PTC fuse can be added to the unswitched +48-V line to protect the system supply and wiring infrastructure from secondary building wiring faults.

When the PSEPM is enabled and a PD is discovered and optionally classified, power is ramped to the PD at a controlled current ramp rate to reduce EMI. Upon completion of the current ramp up, the port current remains limited at less than 400 mA. Upon startup the port can remain in current limit for a timed value of 50 ms which allows the bulk filter capacitance of the PD to charge. Once a PD is successfully powered and the external N-channel MOSFET is fully on, the average and peak current to the PD is continuously monitored. A disconnected load is detected if the average current falls below 10 mA. An overcurrent is detected if the average current exceeds 375 mA and/or the peak current exceeds 425 mA. If any of these conditions exist, status bits are set in the per-port read register set and the power is removed from the load.

For maximum rejection of external wiring and power supply noise sources during the measurement of line current, voltage, resistance or capacitance in discovery, classification and powered modes, a proprietary low noise A/D converter is used. Converted measurements are processed and compared with digital set-points for limit compliance. The 12-bit conversion of this data-acquisition system is available through the read register enabling measurement of the discovery resistance, classification current and powered mode port running current and voltage. This is a valuable feature in ethernet switch management as it allows monitoring of real-time parameters across the system network.

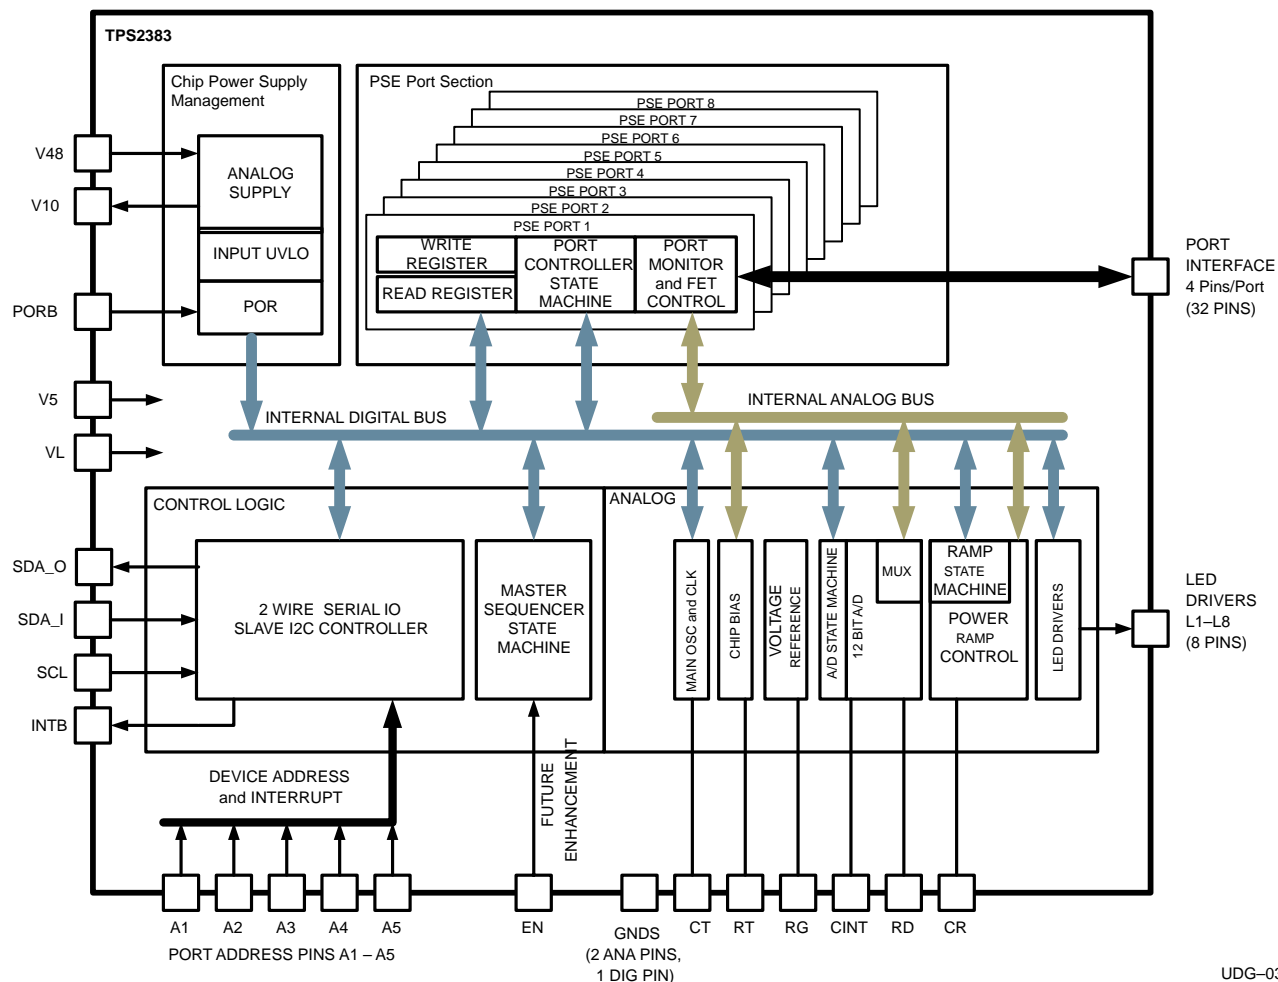

The TPS2383 is available in a full function 64 pin LQFP package.

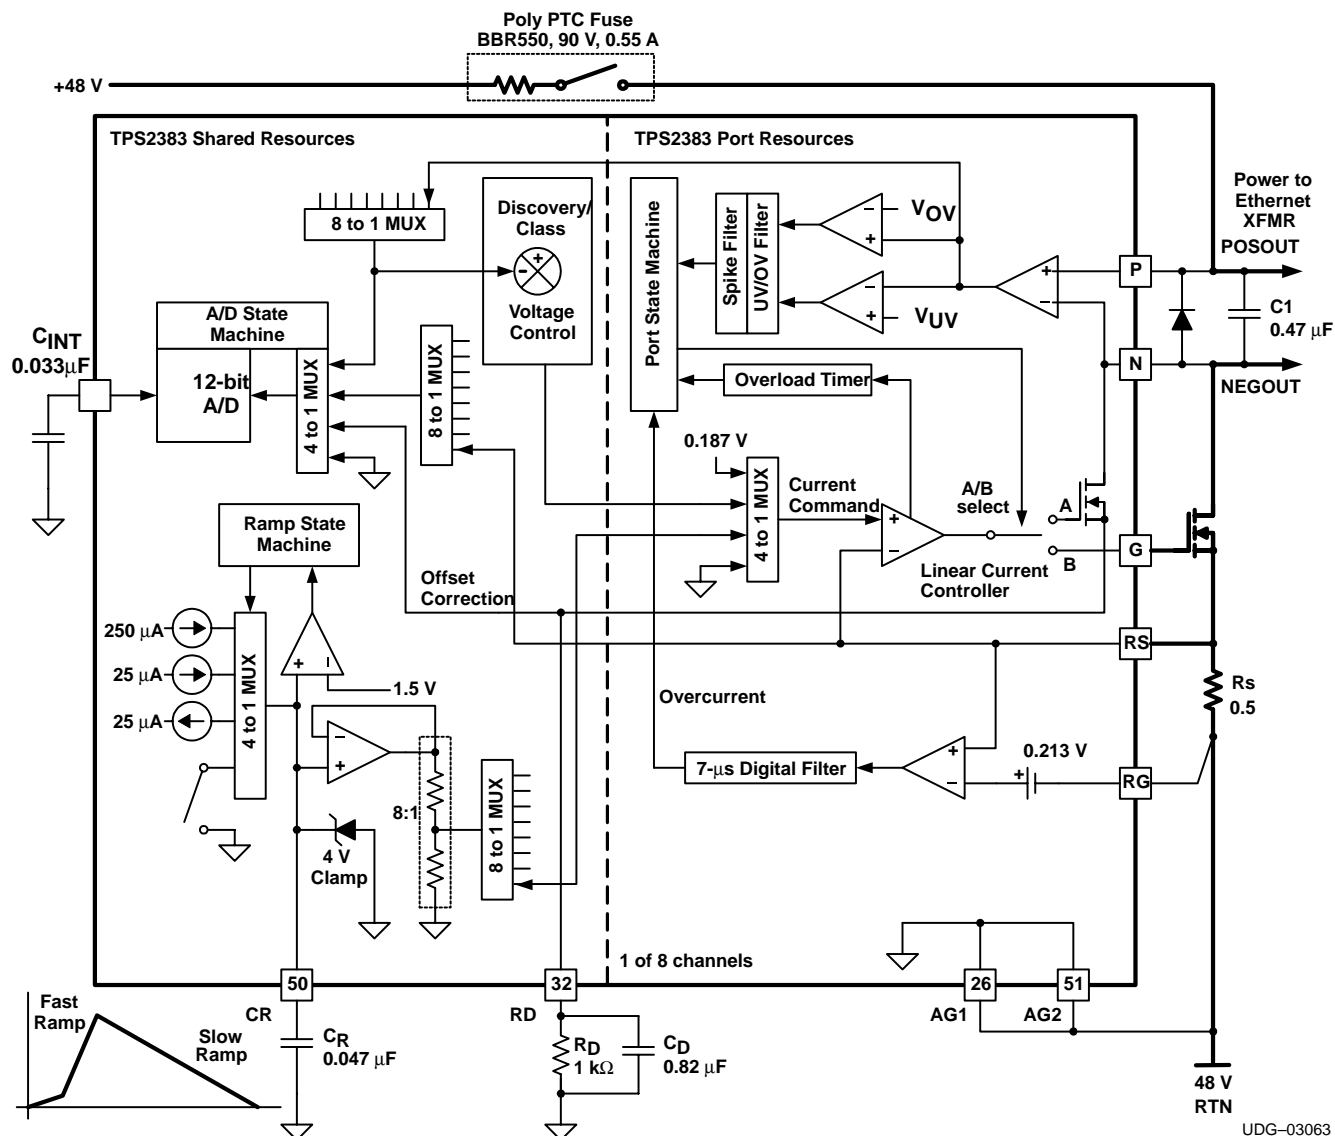

## TPS2383 Evaluation Board

The full performance features of the TPS2383/MSP430 chipset can be demonstrated with the TPS2383EVM–001 evaluation board. The TPS2383EVM–001 is a scaleable system that can be expanded to support 48 ports using a single microcontroller. This evaluation design can be used as a hardware/firmware template for modification to specific customer requirements. Please contact Texas Instruments or refer to the TPS2383EVM–001 Users Guide (SLUUxxx) for complete information.

## FUNCTIONAL BLOCK DIAGRAM

# TPS2383 BLOCK DIAGRAM – SHARED PORT ANALOG RESOURCES

UDG-03063

---

## FUNCTIONAL DESCRIPTION

### SEPM STATE MACHINES

The TPS2383 has circuit resources that are common to each port and circuit resources that are shared by all ports. Five independent state machines are used to control the common and shared PSEPM resources. Port control, UV/OV/OC and overload protection are all features that are common to each port. Data acquisition and power ramping are shared functions for all the ports.

The master sequencer state machine is used to index the port presently being serviced and to distribute the shared resources to the currently selected port. The single master sequencer is responsible for incrementally accessing ports 1 through 8 and allowing those ports to process register data when they are accessed. Ports 1 through 8 each have a port sequencer, which controls all the power enabling and fault protection functions of the port per the register commands. The A/D has an A/D Sequencer that triggers, cycles and signals the port and master sequencer upon completion. The ramp sequencer controls the power ramping resource and is triggered by the port and master sequencer and provides a completion signal when power ramping is over.

Upon power-up the master sequencer is enabled and running after a POR delay and begins acting on register commands. A shorter POR delay releases the reset on the I<sup>2</sup>C function and registers before the port reset is removed. This arrangement allows for register setup and polling over the I<sup>2</sup>C bus quickly upon power up but ensures that power cannot be applied until the power supply is fully energized and stable. The default power-up state for all command registers is a null condition. The state sequence order of the TPS2383 is discovery, classification and power delivery if a POE compliant device is detected on the other end of the data cable.

The master sequencer powers-up in a default free-running mode. The TPS2383 also has a JOG mode. By setting the JOG\_MODE register bit high, the master sequencer then no longer runs freely, but increments to the next sequential port each time the JOG register bit is set to a logic 1. The JOG bit is self-cleared once the port increments to the next position.

Sequencing starts with port 1 and ends with port 8 and then repeats. The port sequencer signals status information to the master sequencer and skips over disabled ports. When the master sequencer detects an enabled port, it pauses at that port until discovery, classification and power-up is complete before proceeding to the next. When the master sequencer reaches a powered port, it pauses and take a reading of the ports run-time current and/or voltage before proceeding to the next port. When a powered PD load is disconnected, the disconnect event can be detected the next time that port is selected by the master sequencer. When the disable bit of a powered port is set in the corresponding register, that operation is completed the next time the master sequencer selects that port. An overcurrent fault event shuts down the offending port independent of any sequencer state.

### DUAL COLOR LED DRIVERS

The LED driver pins (L1 through L8) can be used to drive single or dual, color LEDs. These LEDs are intended to provide installation or service personnel with the necessary information to install and troubleshoot the system infrastructure. The L<sub>n</sub> pins have internal tri-state drivers. These LEDs can be controlled directly from the I<sup>2</sup>C registers. The reset state of all the LEDs is tri-state. Cross-conduction logic disables both internal high- and low-side MOSFETS if an attempt is made to enable both transistors on a given port. These are high current (10-mA) drivers that can be used for other applications such as the drive of optocouplers or electromechanical devices, or can just be used as an 8-bit data port.

## FUNCTIONAL DESCRIPTION

### I<sup>2</sup>C INTERFACE

The serial interface used in the TPS2383 is a standard two-wire I<sup>2</sup>C slave architecture core. The standard bi-directional SDA lines of the I<sup>2</sup>C architecture are broken out into an independent input and output path. This feature simplifies, earth grounded, controller applications that require opto-isolators to keep the 48-V return of the ethernet power system floating. For applications where opto-isolation is not required, the bi-directional property of the SDA line can be restored by connecting SDA\_I to SDA\_O. The SCL line is a unidirectional input only line as the TPS2383 is always accesses as a slave device and it never controls the bus.

Data transfers that require a data-flow reversal on the SDA line are four-byte operations. This occurs during a TPS2383 port read access cycle where a slave address byte is sent, followed by a port/register address byte write. A second slave address byte is sent followed by the data byte read using the port/register setup from the second byte in the sequence.

Data write transfers to the TPS2383 do not require a data-flow reversal and as such only a three-byte operation is required. The sequence in this case is to send a slave address byte, followed by a write of the port/register address followed by a write of the data byte for the addressed port.

The I<sup>2</sup>C access cycle consists of the following steps 1 through 7 and is also shown in Figure 4.

1. Start sequence (S)
2. Slave address field
3. Read/write
4. Acknowledge
5. Port/register address or data field
6. Acknowledge/not acknowledge
7. Stop sequence (P)

The I<sup>2</sup>C interface and the port read write registers are held in active reset until input voltage is within specification and the internal POR timer has timed out.

### Start/Stop

The high-to-low transition of SDA while SCL is high defines the start condition. The low-to-high transition of SDA while SCL is high defines the stop condition. The master device initiates all start and stop conditions.

A first serial packet enclosed within start and stop bits, consists of a seven-bit address field, read/write bit, and the acknowledge bit. The acknowledge bit is always generated by the device receiving the address or data field. Five of the seven address bits are used by the TPS2383. The sixth and seventh bit is a placeholder for future expansion. During a write operation to the TPS2383 from the master device, the data field is eight bits. During a read operation where the TPS2383 is writing to the master device, the data field is also eight bits.

## FUNCTIONAL DESCRIPTION

### Chip Address

The address field of the TPS2383 is eight bits and contains five bits of device address select, a read/write bit, and two spare bits per table 1. The leading two bits are not used and are reserved for future port expansion. The five device address select bits follow this. These bits are compared against the hard-wired state of the corresponding, device address select pins (A1 through A5). When the field contents are equivalent to the pin logic states, the device is addressed. These bits are followed by a least significant bit (LSB), which is used to set the read or write condition (1 for read and 0 for write). Following a start condition and an address field, the TPS2383 responds with an acknowledgement by pulling the SDA line low during the ninth clock cycle if the address field is equivalent to the value programmed by the pins. The SDA line remains a stable low while the ninth clock pulse is high.

**Table 1. Address Selection Field**

BIT	FUNCTION
A7	Future expansion (not used)
A6	Future expansion (not used)
A5	Device address. Compared with A5
A4	Device address. Compared with A4
A3	Device address. Compared with A3
A2	Device address. Compared with A2
A1	Device address. Compared with A1
A0	Read/write

### Port/Register Cycle

After the chip address cycle, the TPS2383 accepts eight bits of port/register specific data as defined in Table 2. After receiving the eight-bit data field, the TPS2383 pulls the SDA line high for one clock cycle. A stop condition is then initiated by the transmitting device after the acknowledge pulse. The SDA line transition then latches the selection of the appropriate internal register for the follow on data read or write operation.

**Table 2. Register/Port Addressing**

BIT	FUNCTION	STATE
D7	Future expansion	
D6	Future expansion	
D5	R2, register select MSB	000 = Control (common Write register) 001 = Port Status (per port Read register) 010 = Port Control (per port Write register) 011 = A2D Register low byte (common read register) 100 = A2D Register high byte (common read register) 101 = Chip identification/revision (common read register)
D4	R1, register select

D0		01 = Discovery – classification – power on sequence 10 = Sample powered-mode current 11 = Power-down an active port	

**Run Current/Voltage**

During power delivery, the average value of the port running current or voltage is available from the read register. The slope type converter used produces 12 bits of input offset corrected conversion with a typical integration or averaging period of approximately one line cycle (16 ms). The actual averaging period is set by the CLK frequency and is equivalent to 8192 periods of that frequency. The lower eight bits of this conversion are available at the port register 011. The remaining upper four bits and A/D status bits are available at register 100. The converter span is 4096 bits. The A/D conversion port displays the real time counter output and holds the final static value at the completion of conversion
