16-Bit, 500kHz, MicroPower Sampling
ANALOG-TO-DIGITAL CONVERTER

Check for Samples: ADS8322

FEATURES

- **HIGH-SPEED PARALLEL INTERFACE**
- **500kHz SAMPLING RATE**
- **LOW POWER: 85mW at 500kHz**
- **INTERNAL 2.5V REFERENCE**
- **UNIPOLAR INPUT RANGE**
- **TQFP-32 PACKAGE**

APPLICATIONS

- **CT SCANNERS**
- **HIGH-SPEED DATA ACQUISITION**
- **TEST AND INSTRUMENTATION**
- **MEDICAL EQUIPMENT**

DESCRIPTION

The ADS8322 is a 16-bit, 500kHz analog-to-digital (A/D) converter with an internal 2.5V reference. The device includes a 16-bit capacitor-based successive approximation register (SAR) A/D converter with inherent sample-and-hold. The ADS8322 offers a full 16-bit interface, or an 8-bit option where data are read using two read cycles and eight pins. The ADS8322 is available in a TQFP-32 package and is ensured over the industrial –40°C to +85°C temperature range.

ADS8322

TEXAS INSTRUMENTS

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

THEORY OF OPERATION

The ADS8322 is a high-speed successive approximation register (SAR) A/D converter with an internal 2.5V bandgap reference. The architecture is based on capacitive redistribution, which inherently includes a sample-and-hold function. The basic operating circuit for the ADS8322 is shown in Figure 13.

The ADS8322 requires an external clock to run the conversion process. The clock can be run continuously or it can be gated to conserve power between conversions. This clock can vary between 25kHz (1.25kHz throughput) and 10MHz (500kHz throughput). The duty cycle of the clock is unimportant as long as the minimum HIGH and LOW times are at least 40ns and the clock period is at least 100ns. The minimum clock frequency is governed by the parasitic leakage of the capacitive digital-to-analog (CDAC) capacitors internal to the ADS8322.

The analog input is provided to two input pins, +IN and –IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

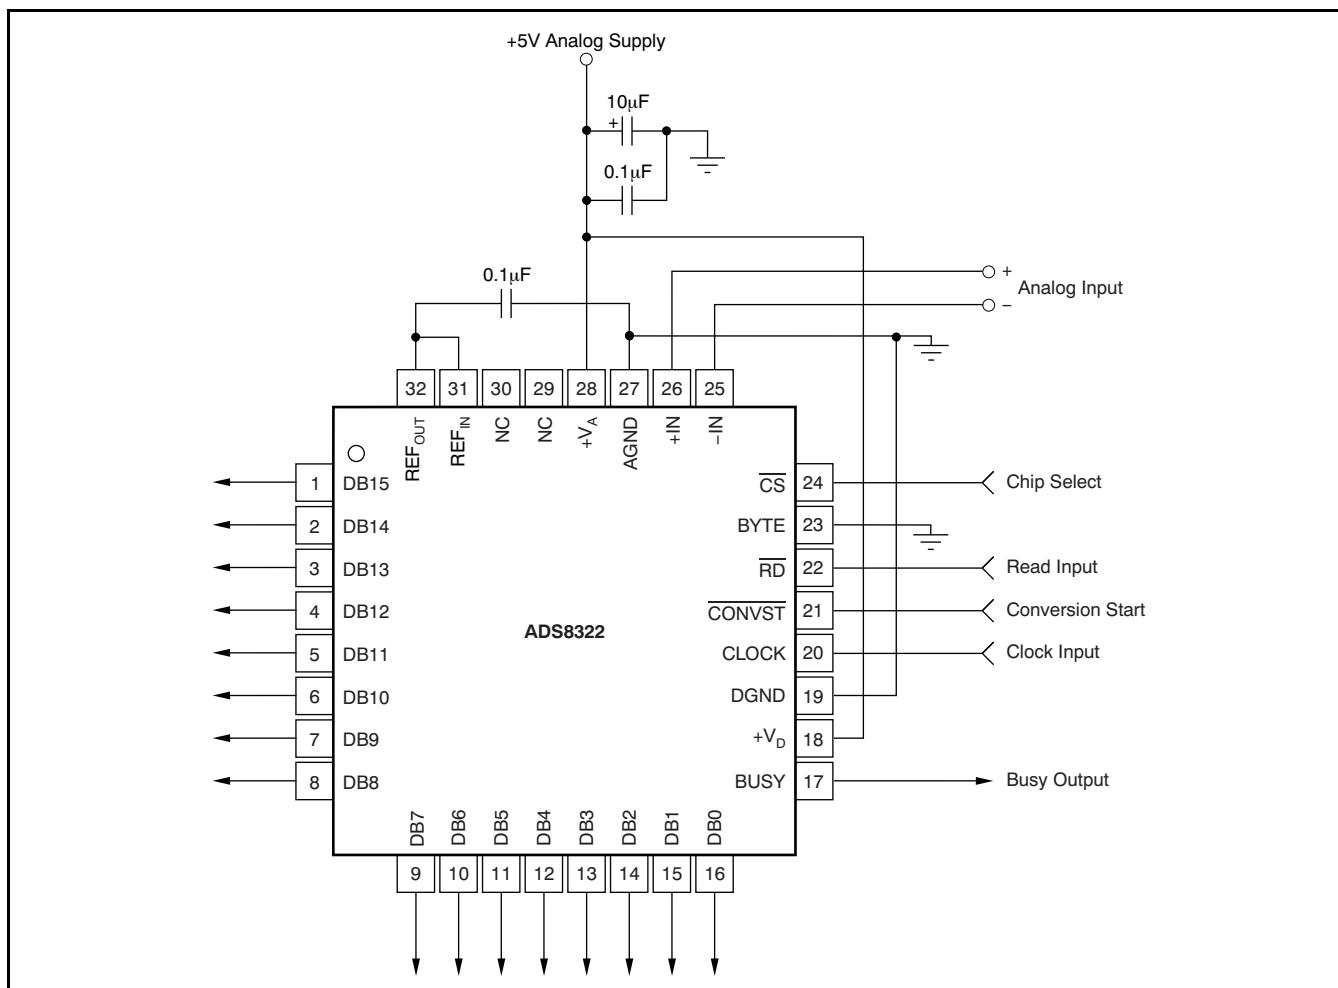

Figure 13. Typical Circuit Configuration

REFERENCE

Under normal operation, the REF$_{OUT}$ pin should be directly connected to the REF$_{IN}$ pin to provide an internal +2.5V reference to the ADS8322. The ADS8322 can operate, however, with an external reference in the range of 1.5V to 2.6V for a corresponding full-scale range of 3.0V to 5.2V.

The internal reference of the ADS8322 is double-buffered. If the internal reference is used to drive an external load, a buffer is provided between the reference and the load applied to the REF$_{OUT}$ pin (the internal reference can typically source and sink 10μA of current). If an external reference is used, the second buffer provides isolation between the external reference and the CDAC. This buffer is also used to recharge all of the CDAC capacitors during conversion.

ANALOG INPUT

When the converter enters the Hold mode, the voltage difference between the +IN and –IN inputs is captured on the internal capacitor array. The voltage on the –IN input is limited between –0.1V and 0.5V, allowing the input to reject small signals which are common to both the +IN and –IN inputs. The +IN input has a range of –0.1V to +V$_A$ + 0.1V.

The input current on the analog inputs depends upon a number of factors: sample rate, input voltage, and source impedance. Essentially, the current into the ADS8322 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance (25pF) to a 16-bit settling level within the acquisition time (400ns) of the device. When the converter goes into Hold mode, the input impedance is greater than 1GΩ.

Care must be taken regarding the absolute analog input voltage. To maintain the linearity of the converter, the –IN input should not drop below GND – 100mV or exceed GND + 0.5V. The +IN input should always remain within the range of GND – 100mV to V$_A$ + 100mV. Outside of these ranges, the converter linearity may not meet specifications. To minimize noise, low-bandwidth input signals with low-pass filters should be used.

DIGITAL INTERFACE

TIMING AND CONTROL

See the timing diagram and the *Timing Characteristics* section for detailed information on timing signals and the respective requirements for each.

The ADS8322 uses an external clock (CLOCK) which controls the conversion rate of the CDAC. With a 10MHz external clock, the A/D converter sampling rate is 500kHz, which corresponds to a 2μs maximum throughput time.

Conversions are initiated by bringing the $\overline{\text{CONVST}}$ pin low for a minimum of 20ns (after the 20ns minimum requirement has been met, the $\overline{\text{CONVST}}$ pin can be brought high), while $\overline{\text{CS}}$ is low. The ADS8322 switches from Sample-to-Hold mode on the falling edge of the $\overline{\text{CONVST}}$ command. Following the first rising edge of the external clock after a $\overline{\text{CONVST}}$ low, the ADS8322 begins conversion (this first rising edge of the external clock represents the start of clock cycle one; the ADS8322 requires 16 rising clock edges to complete a conversion). The BUSY output goes high immediately following $\overline{\text{CONVST}}$ going low. BUSY stays high through the conversion process and returns low when the conversion has ended.

Both $\overline{\text{RD}}$ and $\overline{\text{CS}}$ can be high during and before a conversion (although $\overline{\text{CS}}$ must be low when $\overline{\text{CONVST}}$ goes low to initiate a conversion). Both the $\overline{\text{RD}}$ and $\overline{\text{CS}}$ pins are brought low in order to enable the parallel output bus with the conversion.

READING DATA

The ADS8322 outputs full parallel data in Straight Binary format, as shown in Table 1. The parallel output is active when $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are both LOW. The output data should not be read 125ns before the falling edge of $\overline{\text{CONVST}}$ and 10ns after the falling edge. Any other combination of $\overline{\text{CS}}$ and $\overline{\text{RD}}$ will 3-state the parallel output. Refer to Table 1 for ideal output codes.

Table 1. Ideal Input Voltages and Output Codes

DESCRIPTION	ANALOG VALUE	DIGITAL OUTPUT STRAIGHT BINARY	
Full-Scale Range	$2 \bullet V_{REF}$		
Least Significant Bit (LSB)	$2 \bullet V_{REF}/65535$	BINARY CODE	HEX CODE
+Full Scale	$2V_{REF} - 1$ LSB	1111 1111 1111 1111	FFFF
Midscale	V_{REF}	1000 0000 0000 0000	8000
Midscale – LSB	$V_{REF} - 1$ LSB	0111 1111 1111 1111	7FFF
Zero	0	0000 0000 0000 0000	0000

Product Folder Link(s): *ADS8322*

BYTE

The output data appear as a full 16-bit word on DB15- DB0 (MSB-LSB), if BYTE is low. The result may also be read on an 8-bit bus by using only DB7-DB0. In this case two reads are necessary. The first read proceeds as before, leaving BYTE low and reading the eight least significant bits on DB7-DB0, then bringing BYTE high. When BYTE is high, the upper eight bits (D15-D8) appear on DB7-DB0.

NOISE

Figure 14 shows the transition noise of the ADS8322. A low-level dc input was applied to the analog input pins and the converter was put through 8,192 conversions. The digital output of the A/D converter varies in output code due to the internal noise of the ADS8322. This characteristic is true for all 16-bit SAR-type A/D converters. Using a histogram to plot the output codes, the distribution should appear bell-shaped, with the peak of the bell curve representing the nominal code for the input value. The $\pm 1\sigma$, $\pm 2\sigma$, and $\pm 3\sigma$ distributions respectively represent the 68.3%, 95.5%, and 99.7% of all codes. The transition noise can be calculated by dividing the number of codes measured by six; this yields the $\pm 3\sigma$ distribution, or 99.7%, of all codes. Statistically, up to three codes could fall outside the distribution when executing 1,000 conversions. The ADS8322, with five output codes for the $\pm 3\sigma$ distribution, yields a < ± 0.8LSB transition noise at 5V operation. Remember that to achieve this low-noise performance, the peak-to-peak noise of the input signal and reference must be < 50µV.

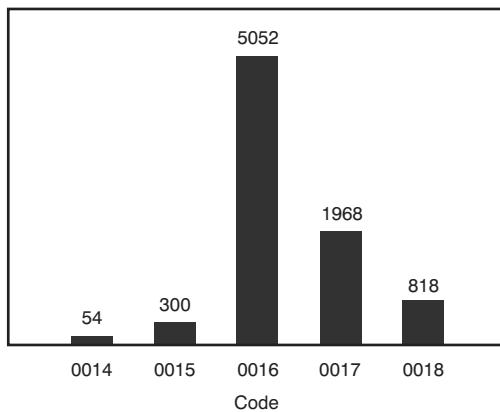

Figure 14. Histogram of 8,192 Conversions of a Low-Level DC Input

AVERAGING

The noise of the A/D converter can be compensated by averaging the digital codes. By averaging conversion results, transition noise is reduced by a factor of $1/\sqrt{n}$, where *n* is the number of averages. For example, averaging four conversion results reduces the transition noise by 1/2 to ± 0.25 LSBs. Averaging should only be used for input signals with frequencies near dc.

For ac signals, a digital filter can be used to low-pass filter and decimate the output codes. This configuration works in a similar manner to averaging: for every decimation by 2, the signal-to-noise ratio improves by 3dB.

LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS8322 circuitry. This consideration is particularly true if the CLOCK input is approaching the maximum throughput rate.

As the ADS8322 offers single-supply operation, it is often used in close proximity with digital logic, microcontrollers, microprocessors, and digital signal processors. The more digital logic present in the design and the higher the switching speed, the more difficult it is to achieve good performance from the converter.

The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections and digital inputs that occur just before latching the output of the analog comparator. Thus, during any single conversion for an n-bit SAR converter, there are n *windows* in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, or nearby digital logic or high-power devices.

The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. These errors can change if the external event changes in time with respect to the CLOCK input.

On average, the ADS8322 draws very little current from an external reference, as the reference voltage is internally buffered. If the reference voltage is external and originates from an op amp, make sure that it can drive the bypass capacitor or capacitors without oscillation.

The AGND and DGND pins should be connected to a clean ground point. In all cases, this point should be the *analog* ground. Avoid connections which are too close to the grounding point of a microcontroller or digital signal processor. If required, run a ground trace directly from the converter to the power supply entry point. The ideal layout will include an analog ground plane dedicated to the converter and associated analog circuitry.

As with the GND connections, V_{DD} should be connected to a +5V power supply plane, or trace, that is separate from the connection for digital logic until they are connected at the power entry point. Power to the ADS8322 should be clean and well-bypassed. A 0.1µF ceramic bypass capacitor should be placed as close to the device as possible. In addition, a 1µF to 10µF capacitor is recommended. If needed, an even larger capacitor and a 5Ω or 10Ω series resistor may be used to low-pass filter a noisy supply. In some situations, additional bypassing may be required, such as a 100µF electrolytic capacitor, or even a *Pi* filter made up of inductors and capacitors—all designed to essentially low-pass filter the +5V supply, removing the high-frequency noise.

REVISION HISTORY

(1) Status: For more details on status, see our product life cycle.

(2) Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

(3) RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

(4) Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

(5) MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

(6) Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

NOTES: A.   All linear dimensions are in millimeters.
          B.   This drawing is subject to change without notice.
          C.   Publication IPC−7351 is recommended for alternate designs.
          D.   Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should
               contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
          E.   Customers should contact their board fabrication site for recommended solder mask tolerances between and around
               signal pads.
