## PIN FUNCTIONS

**Exposed Pad (DCB Package Only):** Exposed pad may be left open or connected to  $V_{SS}$ .

**GATE:** Gate Drive Output. The GATE pin pulls high, enhancing the N-channel MOSFET when the load current creates more than 30mV of voltage drop across the MOSFET. When the load current is small, the gate is actively driven to maintain 30mV across the MOSFET. If reverse current flows, a fast pull-down circuit connects the GATE to the SOURCE pin within 0.3μs, turning off the MOSFET.

**IN:** Voltage Sense and Supply Voltage. IN is the anode of the ideal diode. The voltage sensed at this pin is used to control the MOSFET gate.

**NC (MS8 and S8 Packages):** No Connection. Not internally connected.

**OUT:** Drain Voltage Sense. OUT is the cathode of the ideal diode and the common output when multiple LTC4359s

are configured as an ideal diode-OR. It connects either directly or through a 2k resistor to the drain of the N-channel MOSFET. The voltage sensed at this pin is used to control the MOSFET gate.

**SHDN:** Shutdown Control Input. The LTC4359 can be shut down to a low current mode by pulling the SHDN pin below 0.6V. Pulling this pin above 2V or disconnecting it allows an internal 2.6μA current source to turn the part on. Maintain board leakage to less than 100nA for proper operation. The SHDN pin can be pulled up to 100V or down to -40V with respect to  $V_{SS}$  without damage. If the shutdown feature is not used, connect SHDN to IN.

**SOURCE:** Source Connection. SOURCE is the return path of the gate fast pull-down. Connect this pin as close as possible to the source of the external N-channel MOSFET.

**V<sub>SS</sub>:** Supply Voltage Return and Device Ground.

## BLOCK DIAGRAM

## OPERATION

The LTC4359 controls an external N-channel MOSFET to form an ideal diode. The GATE amplifier (see Block Diagram) senses across IN and OUT and drives the gate of the MOSFET to regulate the forward voltage to 30mV. As the load current increases, GATE is driven higher until a point is reached where the MOSFET is fully on. Further increases in load current result in a forward drop of  $R_{DS(ON)} \cdot I_{LOAD}$ .

If the load current is reduced, the GATE amplifier drives the MOSFET gate lower to maintain a 30mV drop. If the input voltage is reduced to a point where a forward drop of 30mV cannot be supported, the GATE amplifier drives the MOSFET off.

In the event of a rapid drop in input voltage, such as an input short-circuit fault or negative-going voltage spike, reverse current temporarily flows through the MOSFET. This current is provided by any load capacitance and by other supplies or batteries that feed the output in diode-OR applications. The FPD COMP (Fast Pull-Down Comparator)

quickly responds to this condition by turning the MOSFET off in 300ns, thus minimizing the disturbance to the output bus.

The IN, SOURCE, GATE and  $\overline{SHDN}$  pins are protected against reverse inputs of up to  $-40V$ . The NEGATIVE COMP detects negative input potentials at the SOURCE pin and quickly pulls GATE to SOURCE, turning off the MOSFET and isolating the load from the negative input.

When pulled low the  $\overline{SHDN}$  pin turns off most of the internal circuitry, reducing the quiescent current to 9µA and holding the MOSFET off. The  $\overline{SHDN}$  pin may be either driven high or left open to enable the LTC4359. If left open, an internal 2.6µA current source pulls  $\overline{SHDN}$  high. In applications where Q1 is replaced with back-to-back MOSFETs, the  $\overline{SHDN}$  pin serves as an on/off control for the forward path, as well as enabling the diode function.

## APPLICATIONS INFORMATION

Blocking diodes are commonly placed in series with supply inputs for the purpose of ORing redundant power sources and protecting against supply reversal. The LTC4359 replaces diodes in these applications with a MOSFET to reduce both the voltage drop and power loss associated with a passive solution. The curve shown on page 1 illustrates the dramatic improvement in power loss achieved in a practical application. This represents significant savings in board area by greatly reducing power dissipation in the pass device. At low input voltages, the improvement in forward voltage loss is readily appreciated where headroom is tight, as shown in Figure 2.

The LTC4359 operates from 4V to 80V and withstands an absolute maximum range of -40V to 100V without damage. In automotive applications the LTC4359 operates through load dump, cold crank and two-battery jumps, and it survives reverse battery connections while also protecting the load.

A 12V/20A ideal diode application is shown in Figure 1. Several external components are included in addition to the MOSFET, Q1. Ideal diodes, like their nonideal counterparts, exhibit a behavior known as reverse recovery. In combination with parasitic or intentionally introduced inductances, reverse recovery spikes may be generated by an ideal diode during commutation. D1, D2 and R1 protect against these spikes which might otherwise exceed the LTC4359's -40V to 100V survival rating. C<sub>OUT</sub> also plays a role in absorbing reverse recovery energy. Spikes and protection schemes are discussed in detail in the Input Short-Circuit Faults section.

Figure 2. Forward Voltage Drop Comparison Between MOSFET and Schottky Diode

It is important to note that the  $\overline{\text{SHDN}}$  pin, while disabling the LTC4359 and reducing its current consumption to 9 $\mu$ A, does not disconnect the load from the input since Q1's body diode is ever-present. A second MOSFET is required for load switching applications.

### MOSFET Selection

All load current passes through an external MOSFET, Q1. The important characteristics of the MOSFET are on-resistance,  $R_{\text{DS(ON)}}$ , the maximum drain-source voltage,  $\text{BV}_{\text{DSS}}$ , and the gate threshold voltage  $V_{\text{GS(TH)}}$ .

Gate drive is compatible with 4.5V logic-level MOSFETs over the entire operating range of 4V to 80V. In applications above 8V, standard 10V threshold MOSFETs may be used. An internal clamp limits the gate drive to 15V maximum between the GATE and SOURCE pins. For 24V and higher applications, an external Zener clamp (D4) must be added between GATE and SOURCE to not exceed the MOSFET's  $V_{\text{GS(MAX)}}$  during input shorts.

The maximum allowable drain-source voltage,  $\text{BV}_{\text{DSS}}$ , must be higher than the power supply voltage. If the input is grounded, the full supply voltage will appear across the MOSFET. If the input is reversed, and the output is held up by a charged capacitor, battery or power supply, the sum of the input and output voltages will appear across the MOSFET and  $\text{BV}_{\text{DSS}} > \text{OUT} + |\text{VIN}|$ .

## APPLICATIONS INFORMATION

The MOSFET's on-resistance,  $R_{DS(ON)}$ , directly affects the forward voltage drop and power dissipation. Desired forward voltage drop should be less than that of a diode for reduced power dissipation; 100mV is a good starting point. Choose a MOSFET which has:

$$R_{DS(ON)} < \frac{\text{Forward Voltage Drop}}{I_{LOAD}}$$

The resulting power dissipation is

$$P_d = (I_{LOAD})^2 \cdot R_{DS(ON)}$$

### Shutdown Mode

In shutdown, the LTC4359 pulls GATE low to SOURCE, turning off the MOSFET and reducing its current consumption to 9 $\mu$ A. Shutdown does not interrupt forward current flow, a path is still present through Q1's body diode, as shown in Figure 1. A second MOSFET is needed to block the forward path; see the section Load Switching and Inrush Control. When enabled the LTC4359 operates as an ideal diode. If shutdown is not needed, connect  $\overline{SHDN}$  to IN.  $\overline{SHDN}$  may be driven with a 3.3V or 5V logic signal, or with an open drain or collector. To assert  $\overline{SHDN}$  low, the pull down must sink at least 5 $\mu$ A at 500mV. To enable the part,  $\overline{SHDN}$  must be pulled up to at least 2V. If  $\overline{SHDN}$  is driven with an open drain, open collector or switch contact, an internal pull-up current of 2.6 $\mu$ A (1 $\mu$ A minimum) asserts  $\overline{SHDN}$  high and enables the LTC4359. If leakage from  $\overline{SHDN}$  to ground cannot be maintained at less than 100nA, add a pull-up resistor to >2V to assure turn on. The self-driven open circuit voltage is limited internally to 2.5V. When floating, the impedance is high and  $\overline{SHDN}$  is subject to capacitive coupling from nearby clock lines or traces exhibiting high dV/dt. Bypass  $\overline{SHDN}$  to  $V_{SS}$  with 10nF to eliminate injection. Figure 3a is the simplest way to control the shutdown pin. Since the control signal ground is different from the  $\overline{SHDN}$  pin reference,  $V_{SS}$ , there could be momentary glitches on  $\overline{SHDN}$  during transients. Figures 3b and 3c are alternative solutions that level-shift the control signal and eliminate glitches.

### Input Short-Circuit Faults

The dynamic behavior of an active, ideal diode entering reverse bias is most accurately characterized by a delay followed by a period of reverse recovery. During the delay phase some reverse current is built up, limited by parasitic resistances and inductances. During the reverse recovery

## APPLICATIONS INFORMATION

phase, energy stored in the parasitic inductances is transferred to other elements in the circuit. Current slew rates during reverse recovery may reach 100A/μs or higher.

High slew rates coupled with parasitic inductances in series with the input and output paths may cause potentially destructive transients to appear at the IN, SOURCE and OUT pins of the LTC4359 during reverse recovery. A zero impedance short-circuit directly across the input and ground is especially troublesome because it permits the highest possible reverse current to build up during the delay phase. When the MOSFET finally interrupts the reverse current, the LTC4359 IN and SOURCE pins experience a negative voltage spike, while the OUT pin spikes in the positive direction.

To prevent damage to the LTC4359 under conditions of input short-circuit, protect the IN, SOURCE and OUT pins as shown in Figure 4. The IN and SOURCE pins are protected by clamping to the V<sub>SS</sub> pin with two TransZorbs or TVS. For input voltages 24V and greater, D4 is needed to protect the MOSFET's gate oxide during input short-circuit conditions. Negative spikes, seen after the MOSFET turns off during an input short, are clamped by D2, a 24V TVS. D2 allows reverse inputs to 24V while keeping the MOSFET off and is not required if reverse-input protection is not needed. D1, a 70V TVS, protects IN and SOURCE in

the positive direction during load steps and overvoltage conditions. OUT can be protected by an output capacitor, C<sub>OUT</sub> of at least 1.5μF, a TVS across the MOSFET or by the MOSFET's avalanche breakdown. Care must be taken if the MOSFET's avalanche breakdown is used to protect the OUT pin. The MOSFET's BV<sub>DSS</sub> must be sufficiently lower than 100V, and the MOSFET's avalanche energy rating must be ample enough to absorb the inductive energy. If a TVS across the MOSFET or the MOSFET avalanche is used to protect the OUT pin, C<sub>OUT</sub> can be reduced to 47nF. C<sub>OUT</sub> and R1 preserve the fast turn off time when output parasitic inductance causes the IN and OUT voltages to drop quickly.

### Reverse Input Protection

In the case of a reverse input where negative voltage is present on the input, the components D1, D2 and R1 protect the LTC4359. With reverse inputs more negative than D2's breakdown voltage (24V), current flows from system ground through R1. For applications that must withstand reverse inputs much greater than -24V such that R1's power dissipation is unacceptable, it may be replaced by a diode. If reverse input protection and fast turn off time are not required, R1 can be removed and V<sub>SS</sub> connected to system ground.

**Figure 4. Reverse Recovery Produces Inductive Spikes at the IN, SOURCE and OUT Pins. The Polarity of Step Recovery Is Shown Across Parasitic Inductances**

## APPLICATIONS INFORMATION

Figure 10 shows a +48V application with reverse input protection where D5 is used instead of R1 to eliminate the power dissipation and system ground current when the input reverses to -48V. With -48V input and OUT powered by another supply or held up by output capacitance, D2 (5.1V) and D3 (75V) prevent the LTC4359's OUT-IN pins from exceeding the 100V absolute maximum rating. R2 limits the current into D1, D2 and D3 during a reverse input.

### Paralleling Supplies

Multiple LTC4359s can be used to combine the outputs of two or more supplies for redundancy or for droop sharing, as shown in Figure 5. For redundant supplies, the supply with the highest output voltage sources most or all of the load current. If this supply's output is quickly shorted to ground while delivering load current, the flow of current temporarily reverses and flows backwards through the LTC4359's MOSFET. The LTC4359 senses this reverse current and activates a fast pull-down to quickly turn off the MOSFET.

Figure 5. Redundant Power Supplies

If the other, initially lower, supply was not delivering any load current at the time of the fault, the output falls until the body diode of its ORing MOSFET conducts. Meanwhile, the LTC4359 charges the MOSFET gate with 10µA until the forward drop is reduced to 30mV. If this supply was sharing load current at the time of the fault, its associated ORing MOSFET was already driven partially on. In this case, the LTC4359 will simply drive the MOSFET gate harder in an effort to maintain a drop of 30mV.

Droop sharing can be accomplished if both power supply output voltages and output impedances are nearly equal. The 30mV regulation technique ensures smooth load sharing between outputs without oscillation. The degree of sharing is a function of MOSFET  $R_{DS(ON)}$ , the output impedance of the supplies and their initial output voltages.

### Load Switching and Inrush Control

By adding a second MOSFET as shown in Figure 6, the LTC4359 can be used to control power flow in the forward direction while retaining ideal diode behavior in the reverse direction. The body diodes of Q1 and Q2 prohibit
