|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x008

Type RO, reset 0x0000.0000

| 14:12     | TSEG2    | R/W  | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for Phase2 (see Figure 18-4 on page 896). The bit time quanta is defined by the BRP field.                                                                                                                                                                  |
| 11:8      | TSEG1    | R/W  | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 18-4 on page 896). The bit time quanta is defined by the BRP field.                                                                                                                                                                 |
| 7:6       | SJW      | R/W  | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                                       |
| 5:0       | BRP      | R/W  | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <b>CANBRPE</b> register can be used to further divide the bit time. |

**Register 5: CAN Interrupt (CANINT), offset 0x010**

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the INTID field is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the INTID field is cleared by reading the **CANSTS** register, or until the IE bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

**CAN Interrupt (CANINT)**

**Register 6: CAN Test (CANTST), offset 0x014**

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

**CAN Test (CANTST)**

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                  |       |             |   |                            |   |                                                                                                                                                                         |

**Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018**

This register is used to further divide the bit time set with the BRP bit in the **CANBIT** register. It is write-enabled by setting the CCE bit in the **CANCTL** register.

**CAN Baud Rate Prescaler Extension (CANBRPE)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x018

Type R/W, reset 0x0000.0000

| 3:0       | BRPE     | R/W  | 0x0        | Baud Rate Prescaler Extension<br>0x00-0x0F: Extend the BRP bit in the <b>CANBIT</b> register to values up to 1023. The actual interpretation by the hardware is one more than the value programmed by BRPE (MSBs) and BRP (LSBs). |

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020****Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the **CANIF1MCTL** register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

**CAN IF1 Command Request (CANIF1CRQ)**

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

**CAN IF1 Command Mask (CANIF1CMSK)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x024

Type R/W, reset 0x0000.0000

**Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028****Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088**

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the ID bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

**CAN IF1 Mask 1 (CANIF1MSK1)**

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x028

Type R/W, reset 0x0000.FFFF

|-------|---------------------------------------------------------------------------------------------------------------|
| 0     | The message object is ignored by the message handler.                                                         |
| 1     | The message object is configured and ready to be considered by the message handler within the CAN controller. |

All unused message objects should have this bit cleared during initialization and before clearing the INIT bit in the **CANCTL** register. The MSGVAL bit must also be cleared before any of the following bits are modified or if the message object is no longer required: the ID fields in the **CANIFnARBn** registers, the XTD and DIR bits in the **CANIFnARB2** register, or the DLC field in the **CANIFnMCTL** register.

| 0x0-0x8   | Specifies the number of bytes in the data frame.                                                |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |             |         |                                                                                                 |         |                                                                |
| 0x9-0xF   | Defaults to a data frame with 8 bytes.                                                          |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |             |         |                                                                                                 |         |                                                                |

**Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C**

**Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040**

**Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044**

**Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048**

**Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C**

**Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0**

**Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4**

**Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8**

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

#### CAN IF1 Data A1 (CANIF1DA1)

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100****Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the TXRQST bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The TXRQST bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TXRQST bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TXRQST bits of the second 16 message objects.

**Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140****Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the INTPND bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The INTPND bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the INTPND bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the INTPND bits of the second 16 message objects.

**CAN Message 1 Interrupt Pending (CANMSG1INT)**

**Register 36: CAN Message 1 Valid (CANMSG1VAL), offset 0x160****Register 37: CAN Message 2 Valid (CANMSG2VAL), offset 0x164**

The **CANMSG1VAL** and **CANMSG2VAL** registers hold the MSGVAL bits of the 32 message objects. By reading these bits, the CPU can check which message object is valid. The message valid bit of a specific message object can be changed with the **CANIFnARB2** register.

The **CANMSG1VAL** register contains the MSGVAL bits of the first 16 message objects in the message RAM; the **CANMSG2VAL** register contains the MSGVAL bits of the second 16 message objects in the message RAM.

**CAN Message 1 Valid (CANMSG1VAL)**

## 19 Ethernet Controller

The Stellaris® Ethernet Controller consists of a fully integrated media access controller (MAC) and network physical (PHY) interface. The Ethernet Controller conforms to *IEEE 802.3* specifications and fully supports 10BASE-T and 100BASE-TX standards.

The Stellaris Ethernet Controller module has the following features:

- Conforms to the IEEE 802.3-2002 specification
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant. Requires only a dual 1:1 isolation transformer interface to the line
  - 10BASE-T/100BASE-TX ENDEC, 100BASE-TX scrambler/descrambler
  - Full-featured auto-negotiation
- Multiple operational modes
  - Full- and half-duplex 100 Mbps
  - Full- and half-duplex 10 Mbps
  - Power-saving and power-down modes
- Highly configurable
  - Programmable MAC address
  - LED activity selection
  - Promiscuous mode support
  - CRC error-rejection control
  - User-configurable interrupts
- Physical media manipulation
  - MDI/MDI-X cross-over support through software assist
  - Register-programmable transmit amplitude
  - Automatic polarity correction and 10BASE-T signal reception
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive channel request asserted on packet receipt
  - Transmit channel request asserted on empty transmit FIFO

## 19.1 Block Diagram

As shown in Figure 19-1 on page 933, the Ethernet Controller is functionally divided into two layers: the Media Access Controller (MAC) layer and the Network Physical (PHY) layer. These layers correspond to the OSI model layers 2 and 1, respectively. The CPU accesses the Ethernet Controller via the MAC layer. The MAC layer provides transmit and receive processing for Ethernet frames. The MAC layer also provides the interface to the PHY layer via an internal Media Independent Interface (MII). The PHY layer communicates with the Ethernet bus.

Figure 19-1. Ethernet Controller

Figure 19-2 on page 933 shows more detail of the internal structure of the Ethernet Controller and how the register set relates to various functions.

Figure 19-2. Ethernet Controller Block Diagram

## 19.2 Signal Description

The following table lists the external signals of the Ethernet Controller and describes the function of each. The Ethernet LED signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the LED signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 446) should be set to choose the LED function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 464) to assign the LED0 and LED1 signals to the specified GPIO port pins. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 423. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 19-1. Ethernet Signals (100LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                 |

Table 19-2. Ethernet Signals (108BGA) (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                           |
|----------|------------|--------------------------|----------|--------------------------|---------------------------------------------------------------------------------------|
| XTALPPHY | J2         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input or external clock reference input. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 19.3 Functional Description

**Note:** A 12.4-kΩ resistor should be connected between the ERBIAS and ground. The 12.4-kΩ resistor should have a 1% tolerance and should be located in close proximity to the ERBIAS pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The functional description of the Ethernet Controller is discussed in the following sections.

### 19.3.1 MAC Operation

The following sections describe the operation of the MAC layer, including an overview of the Ethernet frame format, the MAC layer FIFOs, Ethernet transmission and reception options, and LED indicators.

#### 19.3.1.1 Ethernet Frame Format

Ethernet data is carried by Ethernet frames. The basic frame format is shown in Figure 19-3 on page 935.

Figure 19-3. Ethernet Frame

| Preamble   | SFD       | Destination Address | Source Address | Length/<br>Type | Data               | FCS        |
|------------|-----------|---------------------|----------------|-----------------|--------------------|------------|
| 7<br>Bytes | 1<br>Byte | 6<br>Bytes          | 6<br>Bytes     | 2<br>Bytes      | 46 - 1500<br>Bytes | 4<br>Bytes |

The seven fields of the frame are transmitted from left to right. The bits within the frame are transmitted from least to most significant bit.

- Preamble

The Preamble field is used to synchronize with the received frame's timing. The preamble is 7 octets long.

- Start Frame Delimiter (SFD)

The SFD field follows the preamble pattern and indicates the start of the frame. Its value is 1010.1011b.

- Destination Address (DA)

This field specifies destination addresses for which the frame is intended. The LSB (bit 16 of DA oct 1 in the frame, see Table 19-3 on page 937) of the DA determines whether the address is an individual (0), or group/multicast (1) address.

- Source Address (SA)

The source address field identifies the station from which the frame was initiated.

- Length/Type Field

The meaning of this field depends on its numeric value. This field can be interpreted as length or type code. The maximum length of the data field is 1500 octets. If the value of the Length/Type field is less than or equal to 1500 decimal, it indicates the number of MAC client data octets. If the value of this field is greater than or equal to 1536 decimal, then it encodes the type interpretation. The meaning of the Length/Type field when the value is between 1500 and 1536 decimal is unspecified by the IEEE 802.3 standard. However, the Ethernet Controller assumes type interpretation if the value of the Length/Type field is greater than 1500 decimal. The definition of the Type field is specified in the IEEE 802.3 standard. The first of the two octets in this field is most significant.

- Data

The data field is a sequence of octets that is at least 46 in length, up to 1500 in length. Full data transparency is provided so any values can appear in this field. A minimum frame size of 46 octets is required to meet the IEEE standard. If the frame size is too small, the Ethernet Controller automatically appends extra bits (a pad), thus the pad can have a size of 0 to 46 octets. Data padding can be disabled by clearing the PADEN bit in the **Ethernet MAC Transmit Control (MACTCTL)** register.

For the Ethernet Controller, data sent/received can be larger than 1500 bytes without causing a Frame Too Long error. Instead, a FIFO overrun error is reported using the FOV bit in the **Ethernet MAC Raw Interrupt Status (MACRIS)** register when the frame received is too large to fit into the Ethernet Controller's 2K RAM.

- Frame Check Sequence (FCS)

The frame check sequence carries the cyclic redundancy check (CRC) value. The CRC is computed over the destination address, source address, length/type, and data (including pad) fields using the CRC-32 algorithm. The Ethernet Controller computes the FCS value one nibble at a time. For transmitted frames, this field is automatically inserted by the MAC layer, unless disabled by clearing the CRC bit in the **MACTCTL** register. For received frames, this field is automatically checked. If the FCS does not pass, the frame is not placed in the RX FIFO, unless the FCS check is disabled by clearing the BADCRC bit in the **MACRCTL** register.

### 19.3.1.2 MAC Layer FIFOs

The Ethernet Controller is capable of simultaneous transmission and reception. This feature is enabled by setting the DUPLEX bit in the **MACTCTL** register.

For Ethernet frame transmission, a 2-KB transmit FIFO is provided that can be used to store a single frame. While the *IEEE 802.3 specification* limits the size of an Ethernet frame's payload section to 1500 Bytes, the Ethernet Controller places no such limit. The full buffer can be used for a payload of up to 2032 bytes (as the first 16 bytes in the FIFO are reserved for destination address, source address and length/type information).

For Ethernet frame reception, a 2-KB receive FIFO is provided that can be used to store multiple frames, up to a maximum of 31 frames. If a frame is received, and there is insufficient space in the RX FIFO, an overflow error is indicated using the FOV bit in the **MACRIS** register.

For details regarding the TX and RX FIFO layout, refer to Table 19-3 on page 937. Please note the following difference between TX and RX FIFO layout. For the TX FIFO, the Data Length field in the first FIFO word refers to the Ethernet frame data payload, as shown in the 5th to nth FIFO positions. For the RX FIFO, the Frame Length field is the total length of the received Ethernet frame, including the Length/Type bytes and the FCS bits.

If FCS generation is disabled by clearing the CRC bit in the **MACTCTL** register, the last word in the TX FIFO must contain the FCS bytes for the frame that has been written to the FIFO.

Also note that if the length of the data payload section is not a multiple of 4, the FCS field is not aligned on a word boundary in the FIFO. However, for the RX FIFO, the beginning of the next frame is always on a word boundary.

**Table 19-3. TX & RX FIFO Organization**

| FIFO Word Read/Write Sequence | Word Bit Fields | TX FIFO (Write)                    | RX FIFO (Read)                      |
|-------------------------------|-----------------|------------------------------------|-------------------------------------|
| 1st                           | 7:0             | Data Length Least Significant Byte | Frame Length Least Significant Byte |
|                               | 15:8            | Data Length Most Significant Byte  | Frame Length Most Significant Byte  |
|                               | 23:16           | DA oct 1                           |                                     |
|                               | 31:24           | DA oct 2                           |                                     |
| 2nd                           | 7:0             | DA oct 3                           |                                     |
|                               | 15:8            | DA oct 4                           |                                     |
|                               | 23:16           | DA oct 5                           |                                     |
|                               | 31:24           | DA oct 6                           |                                     |
| 3rd                           | 7:0             | SA oct 1                           |                                     |
|                               | 15:8            | SA oct 2                           |                                     |
|                               | 23:16           | SA oct 3                           |                                     |
|                               | 31:24           | SA oct 4                           |                                     |
| 4th                           | 7:0             | SA oct 5                           |                                     |
|                               | 15:8            | SA oct 6                           |                                     |
|                               | 23:16           | Len/Type Most Significant Byte     |                                     |
|                               | 31:24           | Len/Type Least Significant Byte    |                                     |
| 5th to nth                    | 7:0             | data oct n                         |                                     |
|                               | 15:8            | data oct n+1                       |                                     |
|                               | 23:16           | data oct n+2                       |                                     |
|                               | 31:24           | data oct n+3                       |                                     |
| last                          | 7:0             | FCS 1 <sup>a</sup>                 |                                     |
|                               | 15:8            | FCS 2 <sup>a</sup>                 |                                     |
|                               | 23:16           | FCS 3 <sup>a</sup>                 |                                     |
|                               | 31:24           | FCS 4 <sup>a</sup>                 |                                     |

a. If the CRC bit in the **MACTCTL** register is clear, the FCS bytes must be written with the correct CRC. If the CRC bit is set, the Ethernet Controller automatically writes the FCS bytes.

### 19.3.1.3 Ethernet Transmission Options

At the MAC layer, the transmitter can be configured for both full-duplex and half-duplex operation by using the DUPLEX bit in the **MACTCTL** register. Note that in 10BASE-T half-duplex mode, the transmitted data is looped back on the receive path.

The Ethernet Controller automatically generates and inserts the Frame Check Sequence (FCS) at the end of the transmit frame when the CRC bit in the **MACTCTL** register is set. However, for test purposes, this feature can be disabled in order to generate a frame with an invalid CRC by clearing the CRC bit.

The *IEEE 802.3 specification* requires that the Ethernet frame payload section be a minimum of 46 bytes. The Ethernet Controller automatically pads the data section if the payload data section loaded

into the FIFO is less than the minimum 46 bytes when the PADEN bit in the **MACTCTL** register is set. This feature can be disabled by clearing the PADEN bit.

The transmitter must be enabled by setting the TXEN bit in the **MACTCTL** register.

#### 19.3.1.4 Ethernet Reception Options

The Ethernet Controller RX FIFO should be cleared during software initialization. The receiver should first be disabled by clearing the RXEN bit in the **Ethernet MAC Receive Control (MACRCTL)** register, then the FIFO can be cleared by setting the RSTFIFO bit in the **MACRCTL** register.

The receiver automatically rejects frames that contain bad CRC values in the FCS field. In this case, a Receive Error interrupt is generated and the receive data is lost. To accept all frames, clear the BADCRC bit in the **MACRCTL** register.

In normal operating mode, the receiver accepts only those frames that have a destination address that matches the address programmed into the **Ethernet MAC Individual Address 0 (MACIA0)** and **Ethernet MAC Individual Address 1 (MACIA1)** registers. However, the Ethernet receiver can also be configured for Promiscuous and Multicast modes by setting the PRMS and AMUL bits in the **MACRCTL** register. It is important to note that when the receiver is enabled, all valid frames with a broadcast address of FF-FF-FF-FF-FF-FF in the Destination Address field are received and stored in the RX FIFO, even if the AMUL bit is not set.

#### 19.3.1.5 LED Indicators

The Ethernet Controller supports two LED signals that can be used to indicate various states of operation. These signals are mapped to the LED0 and LED1 pins. By default, these pins are configured as GPIO signals (PF3 and PF2). For the Ethernet Controller to drive these signals, they must be reconfigured to their hardware function. See “General-Purpose Input/Outputs (GPIOs)” on page 423 for additional details. The function of these pins is programmable using the **Ethernet MAC LED Encoding (MACLED)** register. Refer to page 968 for additional details on how to program these LED functions.

#### 19.3.2 Internal MII Operation

For the MII management interface to function properly, the MDIO signal must be connected through a 10 kΩ pull-up resistor to the +3.3 V supply. Failure to connect this pull-up resistor prevents management transactions on this internal MII to function. Note that it is possible for data transmission across the MII to still function since the PHY layer auto-negotiates the link parameters by default.

For the MII management interface to function properly, the internal clock must be divided down from the system clock to a frequency no greater than 2.5 MHz. The **Ethernet MAC Management Divider (MACMDV)** register contains the divider used for scaling down the system clock. See page 963 for more details about the use of this register.

#### 19.3.3 PHY Operation

The Physical Layer (PHY) in the Ethernet Controller includes integrated ENDECs, scrambler/descrambler, dual-speed clock recovery, and full-featured auto-negotiation functions. The transmitter includes an on-chip pulse shaper and a low-power line driver. The receiver has an adaptive equalizer and a baseline restoration circuit required for accurate clock and data recovery. The transceiver interfaces to Category-5 unshielded twisted pair (Cat-5 UTP) cabling for 100BASE-TX applications, and Category-3 unshielded twisted pair (Cat-3 UTP) for 10BASE-T applications. The Ethernet Controller is connected to the line media via dual 1:1 isolation transformers. No external filter is required.

### 19.3.3.1 Clock Selection

The Ethernet Controller can be clocked from an on-chip crystal oscillator which can also be driven by an external oscillator. When using the on-chip crystal oscillator, a 25-MHz crystal should be connected between the XTALPPHY and XTALNPY pins. Alternatively, an external 25-MHz clock input can be connected to the XTALPPHY pin. In this mode of operation, a crystal is not required and the XTALNPY pin should be left unconnected. The Ethernet oscillator is powered down when the EPHY0 bit in the **Run Mode Clock Gating Control Register 2 (RCGC2)** register is clear. After setting the EPHY0 bit, software must wait 3.5 ms before accessing any of the MII Management registers. See “Ethernet Controller” on page 1235 for more information regarding the specifications of the Ethernet Controller.

### 19.3.3.2 Auto-Negotiation

The Ethernet Controller supports the auto-negotiation functions of Clause 28 of the *IEEE 802.3* standard for 10/100 Mbps operation over copper wiring. This function is controlled via register settings. The auto-negotiation function is turned on by default, and the ANEGEN bit in the **Ethernet PHY Management Register 0 - Control (MR0)** is set after reset. Software can disable the auto-negotiation function by clearing the ANEGEN bit. The contents of the **Ethernet PHY Management Register - Auto-Negotiation Advertisement (MR4)** are reflected to the Ethernet Controller's link partner during auto-negotiation via fast-link pulse coding.

Once auto-negotiation is complete, the SPEED bit in the **Ethernet PHY Management Register 31 - PHY Special Control/Status (MR31)** register reflects the actual speed. The AUTODONE bit in **MR31** is set to indicate that auto-negotiation is complete. Setting the RANEG bit in the **MR0** register also causes auto-negotiation to restart.

### 19.3.3.3 Polarity Correction

The Ethernet Controller is capable of automatic polarity reversal for 10BASE-T and auto-negotiation functions. The XPOL bit in the **Ethernet PHY Management Register 27 -Special Control/Status (MR27)** register is set to indicate the polarity has automatically been reversed.

### 19.3.3.4 MDI/MDI-X Configuration

The Ethernet Controller supports the MDI/MDI-X configuration as defined in *IEEE 802.3-2002 specification* through software assistance. The MDI/MDI-X configuration eliminates the need for cross-over cables when connecting to another device, such as a hub. Software can implement the MDI/MDI-X configuration using a function outlined by the pseudo code below. This code should be called periodically using one of the available timer resources on the Stellaris microcontroller such as the System Tick Timer or one of the General Purpose timers. The following code refers to the LINK bit in the **Ethernet PHY Management Register 1 - Status (MR1)**, the ENON bit in the **Ethernet PHY Management Register 17 - Mode Control/Status (MR17)**, and the EN bit of the **Ethernet PHY MDIX (MDIX)** register.

```
//
// Entry Point for MDI/MDI-X configuration.
//

//
// Increment the Link Active and Energy Detect Timers using the elapsed time
// since the last call to this function. If using a periodic timer, the
// elapsed time should be a constant (the programmed period of the timer).
//
Increment Link Active Timer
```

```

Increment Energy Detect Timer

//
if(No Ethernet Link Active)
{
    //
    // If energy has been detected on the link, reset the Energy Detect Timer.
    // If it is a "new" energy detect, reset the link detect timer also.
    //
    if(Ethernet Energy Detected)
    {
        Reset Energy Detect Timer

        if(New Energy Detect)
        {
            Reset Link Detect Timer
        }
    }

    //
    // If the Energy or Link Detect timer has expired, toggle the MDI/MDI-X
    // mode. Typically, the Energy Detect Timer would be ~62ms, while the
    // Link Detect Timer would be ~2s
    //
    if((Energy Detect Timer Expired) or
        (Link Detect Timer Expired))
    {
        Reset Energy Detect Timer

        if(Random Event)
        {
            Reset Link Detect Timer
            Toggle MDI/MDI-X Mode
        }
    }
}

//
// Here, if an Ethernet Link has been detected, simply reset the timers
// for the next time around.
//
else
{
    Reset Link Detect Timer
    Reset Energy Detect Timer
}

```

### 19.3.3.5 Power Management

The PHY has two power-saving modes:

- Power-Down

#### ■ Energy Detect Power-Down

Power-down mode is activated by setting the PWRDN bit in the **MR0** register. When the PHY is in power-down mode, it consumes minimum power. When the PWRDN bit is cleared, the PHY powers up and is automatically reset.

The energy detect power-down mode is activated by setting the EDPD bit in the **MR17** register. In this mode of operation, when no energy is present on the line, the PHY is powered down, except for the management interface, the SQUELCH circuit and the ENERGYON logic. The ENERGYON logic is used to detect the presence of valid energy from 100BASE-T, 10BASE-T, or auto-negotiation signals. While the PHY is powered down, nothing is transmitted. When link pulses or packets are received, the PHY powers-up. The PHY automatically resets itself into the state it had prior to power down and sets the EONIS bit in the **MR29** register. The first and possibly the second packet to activate the ENERGYON mode may be lost.

### 19.3.4 Interrupts

The Ethernet Controller can generate an interrupt for one or more of the following conditions:

- A frame has been received into an empty RX FIFO
- A frame transmission error has occurred
- A frame has been transmitted successfully
- A frame has been received with inadequate room in the RX FIFO (overflow)
- A frame has been received with one or more error conditions (for example, FCS failed)
- An MII management transaction between the MAC and PHY layers has completed
- One or more of the following PHY layer conditions occurs:
  - Auto-Negotiate Complete
  - Remote Fault
  - Link Partner Acknowledge
  - Parallel Detect Fault
  - Page Received

Refer to **Ethernet PHY Management Register 29 - Interrupt Source Flags (MR29)** (see page 986) for additional details regarding PHY interrupts.

### 19.3.5 DMA Operation

The Ethernet peripheral provides request signals to the  $\mu$ DMA controller and has a dedicated channel for transmit and one for receive. The request is a single type for both channels. Burst requests are not supported. The RX channel request is asserted when a packet is received while the TX channel request is asserted when the transmit FIFO becomes empty.

No special configuration is needed to enable the Ethernet peripheral for use with the  $\mu$ DMA controller.

Because the size of a received packet is not known until the header is examined, it is best to set up the initial  $\mu$ DMA transfer to copy the first 4 words including the packet length plus the Ethernet

header from the RX FIFO when the RX request occurs. The  $\mu$ DMA causes an interrupt when this transfer is complete. Upon entering the interrupt handler, the packet length in the FIFO and the Ethernet header are in a buffer and can be examined. Once the packet length is known, then another  $\mu$ DMA transfer can be set up to transfer the remaining received packet payload from the FIFO into a buffer. This transfer should be initiated by software. Another interrupt occurs when this transfer is done.

Even though the TX channel generates a TX empty request, the recommended way to handle  $\mu$ DMA transfers for transmitting packets is to set up the transfer from the buffer containing the packet to the transmit FIFO, and then to initiate the transfer with a software request. An interrupt occurs when this transfer is complete. For both channels, the "auto-request" transfer mode should be used. See "Micro Direct Memory Access ( $\mu$ DMA)" on page 365 for more details about programming the  $\mu$ DMA controller.

## 19.4 Initialization and Configuration

The following sections describe the hardware and software configuration required to set up the Ethernet Controller.

### 19.4.1 Hardware Configuration

Figure 19-4 on page 942 shows the proper method for interfacing the Ethernet Controller to a 10/100BASE-T Ethernet jack.

**Figure 19-4. Interface to an Ethernet Jack**

The following isolation transformers have been tested and are known to successfully interface to the Ethernet PHY layer.

- Isolation Transformers
  - TDK TLA-6T103
  - TDK TLA-6T118
  - Bel-Fuse S558-5999-46
  - Halo TG22-3506ND

- Halo TG110-S050
  - PCA EPF8023G
  - Pulse PE-68515
  - Valor ST6118
  - YCL 20PMT04
- Isolation transformers with integrated RJ45 connector
    - TDK TLA-6T704
    - Delta RJS-1A08T089A
  - Isolation transformers with integrated RJ45 connector, LEDs and termination resistors
    - Pulse J0011D21B/E
    - Pulse J3011G21DNL

## 19.4.2 Software Configuration

To use the Ethernet Controller, it must be enabled by setting the **EPHY0** and **EMAC0** bits in the **RCGC2** register (see page 285). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module. See page 285. To find out which GPIO port to enable, refer to Table 23-4 on page 1165. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the Ethernet signals to the appropriate pins. See page 464 and Table 23-5 on page 1172.

The following steps can then be used to configure the Ethernet Controller for basic operation.

1. Program the **MACDIV** register to obtain a 2.5 MHz clock (or less) on the internal MII. Assuming a 20-MHz system clock, the **MACDIV** value should be 0x03 or greater.
2. Program the **MACIA0** and **MACIA1** register for address filtering.
3. Program the **MACTCTL** register for Auto CRC generation, padding, and full-duplex operation using a value of 0x16.
4. Program the **MACRCTL** register to flush the receive FIFO and reject frames with bad FCS using a value of 0x18.
5. Enable both the Transmitter and Receive by setting the LSB in both the **MACTCTL** and **MACRCTL** registers.
6. To transmit a frame, write the frame into the TX FIFO using the **Ethernet MAC Data (MACDATA)** register. Then set the **NEWTX** bit in the **Ethernet Mac Transmission Request (MACTR)** register to initiate the transmit process. When the **NEWTX** bit has been cleared, the TX FIFO is available for the next transmit frame.
7. To receive a frame, wait for the **NPR** field in the **Ethernet MAC Number of Packets (MACNP)** register to be non-zero. Then begin reading the frame from the RX FIFO by using the **MACDATA** register. To ensure that the entire packet is received, either use the DriverLib **EthernetPacketGet()** API or compare the number of bytes received to the Length field from the frame to determine when the packet has been completely read.

## 19.5 Register Map

Table 19-4 on page 944 lists the Ethernet MAC and MII Management registers. The MAC register addresses given are relative to the Ethernet base address of 0x4004.8000. The MII Management registers are accessed using the **MACMCTL** register. Note that the Ethernet controller clocks must

be enabled before the registers can be programmed (see page 285). There must be a delay of 3 system clocks after the Ethernet module clock is enabled before any Ethernet module registers are accessed. In addition, the Ethernet oscillator is powered down when the EPHY0 bit in the **Run Mode Clock Gating Control Register 2 (RCGC2)** register is clear. After setting the EPHY0 bit, software must wait 3.5 ms before accessing any of the MII Management registers.

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers and are detailed in Section 22.2.4 of the *IEEE 802.3 specification*. Table 19-4 on page 944 also lists these MII Management registers. All addresses given are absolute and are written directly to the REGADR field of the **Ethernet MAC Management Control (MACMCTL)** register. The format of registers 0 to 15 are defined by the IEEE specification and are common to all PHY layer implementations. The only variance allowed is for features that may or may not be supported by a specific PHY implementation. Registers 16 to 31 are vendor-specific registers, used to support features that are specific to a vendor's PHY implementation.

**Table 19-4. Ethernet Register Map**

| Offset                                                       | Name           | Type  | Reset       | Description                                           | See page |

## 19.6 Ethernet MAC Register Descriptions

The remainder of this section lists and describes the Ethernet MAC registers, in numerical order by address offset. Also see “MII Management Register Descriptions” on page 970.

## Register 1: Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK), offset 0x000

The **MACRIS/MACIACK** register is the interrupt status and acknowledge register. On a read, this register gives the current status value of the corresponding interrupt prior to masking. On a write, setting any bit clears the corresponding interrupt status bit.

### Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK)

Base 0x4004.8000

Offset 0x000

**Register 2: Ethernet MAC Interrupt Mask (MACIM), offset 0x004**

This register allows software to enable/disable Ethernet MAC interrupts. Clearing a bit disables the interrupt, while setting the bit enables it.

**Ethernet MAC Interrupt Mask (MACIM)**

**Register 3: Ethernet MAC Receive Control (MACRCTL), offset 0x008**

This register configures the receiver and controls the types of frames that are received.

It is important to note that when the receiver is enabled, all valid frames with a broadcast address of FF-FF-FF-FF-FF-FF in the Destination Address field are received and stored in the RX FIFO, even if the AMUL bit is not set.

**Register 5: Ethernet MAC Data (MACDATA), offset 0x010**

**Important:** This register is read-sensitive. See the register description for details.

This register enables software to access the TX and RX FIFOs.

Reads from this register return the data stored in the RX FIFO from the location indicated by the read pointer. The read pointer is then auto incremented to the next RX FIFO location. Reading from the RX FIFO when a frame has not been received or is in the process of being received returns indeterminate data and does not increment the read pointer.

Writes to this register store the data in the TX FIFO at the location indicated by the write pointer. The write pointer is then auto incremented to the next TX FIFO location. Writing more data into the TX FIFO than indicated in the length field results in the data being lost. Writing less data into the TX FIFO than indicated in the length field results in indeterminate data being appended to the end of the frame to achieve the indicated length. Attempting to write the next frame into the TX FIFO before transmission of the first has completed results in the data being lost.

Bytes may not be randomly accessed in either the RX or TX FIFOs. Data must be read from the RX FIFO sequentially and stored in a buffer for further processing. Once a read has been performed, the data in the FIFO cannot be re-read. Data must be written to the TX FIFO sequentially. If an error is made in placing the frame into the TX FIFO, the write pointer can be reset to the start of the TX FIFO by writing the TXER bit of the **MACIACK** register and then the data re-written.

**Register 8: Ethernet MAC Threshold (MACTHR), offset 0x01C**

In order to increase the transmission rate, it is possible to program the Ethernet Controller to begin transmission of the next frame prior to the completion of the transmission of the current frame.

**Caution – Extreme care must be used when implementing this function. Software must be able to guarantee that the complete frame is able to be stored in the transmission FIFO prior to the completion of the transmission frame.**

This register enables software to set the threshold level at which the transmission of the frame begins. If the THRESH bits are set to 0x3F, which is the reset value, the early transmission feature is disabled, and transmission does not start until the NEWTX bit is set in the **MACTR** register.

Writing the THRESH field to any value besides 0x3F enables the early transmission feature. Once the byte count of data in the TX FIFO reaches the value derived from the THRESH bits as shown below, transmission of the frame begins. When the THRESH field is clear, transmission of the frame begins after 4 bytes (a single write) are stored in the TX FIFO. Each increment of the THRESH bit field waits for an additional 32 bytes of data (eight writes) to be stored in the TX FIFO. Therefore, a value of 0x01 causes the transmitter to wait for 36 bytes of data to be written while a value of 0x02 makes the wait equal to 68 bytes of written data. In general, early transmission starts when:

$$\text{Number of Bytes} \geq 4 ((\text{THRESH} \times 8) + 1)$$

Reaching the threshold level has the same effect as setting the NEWTX bit in the **MACTR** register. Transmission of the frame begins, and then the number of bytes indicated by the Data Length field is transmitted. Because underrun checking is not performed, if any event, such as an interrupt, delays the filling of the FIFO, the tail pointer may reach and pass the write pointer in the TX FIFO. In this event, indeterminate values are transmitted rather than the end of the frame. Therefore, sufficient bus bandwidth for writing to the TX FIFO must be guaranteed by the software.

If a frame smaller than the threshold level must be sent, the NEWTX bit in the **MACTR** register must be set with an explicit write, which initiates the transmission of the frame even though the threshold limit has not been reached.

If the threshold level is set too small, it is possible for the transmitter to underrun. If this occurs, the transmit frame is aborted, and a transmit error occurs. Note that in this case, the TXER bit in the **MACRIS** is not set, meaning that the CPU receives no indication that a transmit error happened.

**Register 9: Ethernet MAC Management Control (MACMCTL), offset 0x020**

This register enables software to control the transfer of data to and from the MII Management registers in the Ethernet PHY layer. The address, name, type, reset configuration, and functional description of each of these registers can be found in Table 19-4 on page 944 and in “MII Management Register Descriptions” on page 970.

In order to initiate a *read* transaction from the MII Management registers, the WRITE bit must be cleared during the same cycle that the START bit is set.

In order to initiate a *write* transaction to the MII Management registers, the WRITE bit must be set during the same cycle that the START bit is set.

**Register 10: Ethernet MAC Management Divider (MACMDV), offset 0x024**

This register enables software to set the clock divider for the Management Data Clock (MDC). This clock is used to synchronize read and write transactions between the system and the MII Management registers. The frequency of the MDC clock can be calculated from the following formula:

$$F_{mdc} = \frac{F_{ipclk}}{2 \times (\text{MACMDV} + 1)}$$

The clock divider must be written with a value that ensures that the MDC clock does not exceed a frequency of 2.5 MHz.

**Register 13: Ethernet MAC Number of Packets (MACNP), offset 0x034**

This register holds the number of frames that are currently in the RX FIFO. When NPR is 0, there are no frames in the RX FIFO, and the RXINT bit is clear. When NPR is any other value, at least one frame is in the RX FIFO, and the RXINT bit in the **MACRIS** register is set.

**Note:** The FCS bytes are not included in the NPR value. As a result, the NPR value could be zero before the FCS bytes are read from the FIFO. In addition, a new packet could be received before the NPR value reaches zero. To ensure that the entire packet is received, either use the DriverLib EthernetPacketGet() API or compare the number of bytes received to the Length field from the frame to determine when the packet has been completely read.

**Register 16: Ethernet PHY MDIX (MDIX), offset 0x044**

This register enables the transmit and receive lines to be reversed in order to implement the MDI/MDI-X functionality. Software can implement the MDI/MDI-X configuration by using any available timer resource such as SysTick (see “System Timer (SysTick)” on page 119 for more information) to implement this functionality. Once the Ethernet Controller has been configured and enabled, software should check to see if the LINK bit in the **MR1** register has been set within approximately 1 s; if not, set the EN bit of the **MDIX** register to switch the reverse the transmit and receive lines to the PHY layer. Software should check the LINK bit again after approximately another 1 s and if no link has been established, the EN bit should be cleared. Software must continue to change the termination back and forth by setting and clearing the EN bit every 1 s until a link is established.

**19.7 MII Management Register Descriptions**

The *IEEE 802.3 standard* specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers. The **Ethernet MAC Management Control (MACMCTL)** register is used to access the MII Management registers, see page 961. All addresses given are absolute. Addresses not listed are reserved; these addresses should not be written to and any data read should be ignored. Also see “Ethernet MAC Register Descriptions” on page 945.

## Register 17: Ethernet PHY Management Register 0 – Control (MR0), address 0x00

This register enables software to configure the operation of the PHY layer. The default settings of these registers are designed to initialize the Ethernet Controller to a normal operational mode without configuration.

## Register 21: Ethernet PHY Management Register 4 – Auto-Negotiation Advertisement (MR4), address 0x04

This register provides the advertised abilities of the Ethernet Controller used during auto-negotiation. Bits 8:5 represent the Technology Ability Field bits. This field can be overwritten by software to auto-negotiate to an alternate common technology. Writing to this register has no effect until auto-negotiation is re-initiated by setting the RANEG bit in the **MR0** register.

## Register 22: Ethernet PHY Management Register 5 – Auto-Negotiation Link Partner Base Page Ability (MR5), address 0x05

This register provides the advertised abilities of the link partner's Ethernet Controller that are received and stored during auto-negotiation.

### Ethernet PHY Management Register 5 – Auto-Negotiation Link Partner Base Page Ability (MR5)

Base 0x4004.8000

Address 0x05

Type RO, reset 0x0001

## Register 23: Ethernet PHY Management Register 6 – Auto-Negotiation Expansion (MR6), address 0x06

This register enables software to determine the auto-negotiation and next page capabilities of the Ethernet Controller and the link partner after auto-negotiation.

### Ethernet PHY Management Register 6 – Auto-Negotiation Expansion (MR6)

Base 0x4004.8000

Address 0x06

Type RO, reset 0x0000

## Register 27: Ethernet PHY Management Register 29 – Interrupt Status (MR29), address 0x1D

This register contains information about the source of PHY layer interrupts. Reading this register clears any bits that are set. The PHYINT bit is set in the **MACRIS/MACIACK** register whenever any of the bits in this register are set.

## 20 Universal Serial Bus (USB) Controller

The Stellaris® USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 32 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 30 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing.  $\mu$ DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG standard's session request protocol (SRP) and host negotiation protocol (HNP).

The Stellaris USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation with integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 32 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 15 configurable IN endpoints and 15 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop and valid ID detection and interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to three IN endpoints and three OUT endpoints
  - Channel requests asserted when FIFO contains required amount of data

## 20.1 Block Diagram

Figure 20-1. USB Module Block Diagram

## 20.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 446) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 464) to assign the USB signal to the specified GPIO port pin. The USB0VBUS and USB0ID signals are configured by clearing the appropriate DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 423. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

Table 20-1. USB Signals (100LQFP)

| Pin Name  | Pin Number                             | Pin Mux / Pin Assignment                                                  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                   |

## 20.3 Functional Description

**Note:** A 9.1-kΩ resistor should be connected between the USB0RBIAS and ground. The 9.1-kΩ resistor should have a 1% tolerance and should be located in close proximity to the USB0RBIAS pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The Stellaris USB controller provides full OTG negotiation by supporting both the session request protocol (SRP) and the host negotiation protocol (HNP). The session request protocol allows devices on the B side of a cable to request the A side device turn on VBUS. The host negotiation protocol is used after the initial session request protocol has powered the bus and provides a method to determine which end of the cable will act as the Host controller. When the device is connected to non-OTG peripherals or devices, the controller can detect which cable end was used and provides a register to indicate if the controller should act as the Host or the Device controller. This indication and the mode of operation are handled automatically by the USB controller. This auto-detection allows the system to use a single A/B connector instead of having both A and B connectors in the system and supports full OTG negotiations with other OTG devices.

In addition, the USB controller provides support for connecting to non-OTG peripherals or Host controllers. The USB controller can be configured to act as either a dedicated Host or Device, in which case, the USB0VBUS and USB0ID signals can be used as GPIOs. However, when the USB controller is acting as a self-powered Device, a GPIO input or analog comparator input must be connected to VBUS and configured to generate an interrupt when the VBUS level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

**Note:** When the USB module is in operation, MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz.

### 20.3.1 Operation as a Device

This section describes the Stellaris USB controller's actions when it is being used as a USB Device. Before the USB controller's operating mode is changed from Device to Host or Host to Device, software must reset the USB controller by setting the USB0 bit in the **Software Reset Control 2 (SRCR2)** register (see page 299). IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of Start of Frame (SOF) are all described.

When in Device mode, IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB Device. However, in most cases the USB Device should use the dedicated control endpoint on the USB controller's endpoint 0.

### 20.3.1.1 Endpoints

When operating as a Device, the USB controller provides two dedicated control endpoints (IN and OUT) and 30 configurable endpoints (15 IN and 15 OUT) that can be used for communications with a Host controller. The endpoint number and direction associated with an endpoint is directly related to its register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining 30 endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as 15 configurable IN and 15 configurable OUT endpoints. The endpoint pairs are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 20.3.1.2 IN Transactions as a Device

When operating as a USB Device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the 15 configurable IN endpoints are determined by the **USB Transmit FIFO Start Address (USBTXFIFOADD)** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USB Maximum Transmit Data Endpoint n (USBTXMAXPn)** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while data is in the FIFO as unexpected results may occur.

**Single-Packet Buffering**

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the **USB Transmit Control and Status Endpoint n Low (USBTXCSSLn)** register must be set. If the AUTOSET bit in the **USB Transmit Control and Status Endpoint n High (USBTXCSRHn)** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

**Double-Packet Buffering**

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the **USBTXCSSLn** register must be set. If the AUTOSET bit in the **USBTXCSRHn** register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the **USBTXCSSLn** register at this point indicates how many packets may be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the **USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

**20.3.1.3 OUT Transactions as a Device**

When in Device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the 15 configurable OUT endpoints are determined by the **USB Receive FIFO Start Address (USBRXFIFOADD)** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USB Maximum Receive Data Endpoint n (USBRXMAXPn)** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

**Single-Packet Buffering**

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the **USB Receive Control and Status Endpoint n Low (USBRXCSSLn)** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet

has been unloaded, the RXRDY bit must be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the **USB Receive Control and Status Endpoint n High (USBXCSRHN)** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

#### **Double-Packet Buffering**

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the **USBXCSRLn** register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The FULL bit in **USBXCSRLn** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the **USBXCSRHN** register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the **USB Receive Double Packet Buffer Disable (USBXDPKTBUFDIS)** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### **20.3.1.4 Scheduling**

The Device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The Stellaris USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the Device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

### **20.3.1.5 Additional Actions**

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

#### **Stalled Control Transfer**

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the **USB Control and Status Endpoint 0 Low (USBCSRL0)** register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the Device request during the SETUP phase. This condition is detected by the USB controller

when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what should have been the last packet.

3. The Host sends more than **USBRXMAXP<sub>n</sub>** bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

#### **Zero Length OUT Data Packets**

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the Device request has been transferred.

However, if the Host sends a zero-length OUT data packet before the entire length of Device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the **USBCSRL0** register.

#### **Setting the Device Address**

When a Host is attempting to enumerate the USB Device, it requests that the Device change its address from zero to some other value. The address is changed by writing the value that the Host requested to the **USB Device Functional Address (USBFADDR)** register. However, care should be taken when writing to **USBFADDR** to avoid changing the address before the transaction is complete. This register should only be set after the SET\_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the Device has left the STATUS phase. In the case of a SET\_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the Device has responded to the IN request, the **USBFADDR** register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the **USBFADDR** register is set to the new value as soon as the Device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the Device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the Device.

### **20.3.1.6 Device Mode SUSPEND**

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the **USB Interrupt Enable (USBIE)** register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the **USB Power (USBPOWER)** register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling.

To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state. The USB controller is not able to Hibernate because all the internal states are lost as a result.

### 20.3.1.7 Start-of-Frame

When the USB controller is operating in Device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the **USB Frame Value (USBFRAME)** register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the **USBFRAME** register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

### 20.3.1.8 USB RESET

When the USB controller is in Device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USB Endpoint Index (USBEPIDX)** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a RESET interrupt.

When the application software driving the USB controller receives a RESET interrupt, any open pipes are closed and the USB controller waits for bus enumeration to begin.

### 20.3.1.9 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the **SOFTCONN** bit of the **USBPOWER** register. When the **SOFTCONN** bit is set, the PHY is placed in its normal mode, and the **USB0DP/USB0DM** lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it does not respond to any USB signaling except a USB RESET.

When the **SOFTCONN** bit is cleared, the PHY is put into non-driving mode, **USB0DP** and **USB0DM** are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the **SOFTCONN** bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the **SOFTCONN** bit has been set, the USB controller can be disconnected by clearing this bit.

**Note:** The USB controller does not generate an interrupt when the Device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

## 20.3.2 Operation as a Host

When the Stellaris USB controller is operating in Host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Before the USB controller's operating mode is changed from Host to Device or

Device to Host, software must reset the USB controller by setting the USB0 bit in the **Software Reset Control 2 (SRCR2)** register (see page 299). Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, isochronous, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in Device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint to communicate with a Device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a Device's endpoint 0.

### 20.3.2.1 Endpoints

The endpoint registers are used to control the USB endpoint interfaces which communicate with Device(s) that are connected. The endpoints consist of a dedicated control IN endpoint, a dedicated control OUT endpoint, 15 configurable OUT endpoints, and 15 configurable IN endpoints.

The dedicated control interface can only be used for control transactions to endpoint 0 of Devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of Devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, interrupt, or isochronous Device endpoints.

These USB interfaces can be used to simultaneously schedule as many as 15 independent OUT and 15 independent IN transactions to any endpoints on any Device. The IN and OUT controls are paired in three sets of registers. However, they can be configured to communicate with different types of endpoints and different endpoints on Devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a Device's bulk OUT endpoint 1, while the IN portion is communicating with a Device's interrupt IN endpoint 2.

Before accessing any Device, whether for point-to-point communications or for communications via a hub, the relevant **USB Receive Functional Address Endpoint n (USBRXFUNCADDRn)** or **USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn)** registers must be set for each receive or transmit endpoint to record the address of the Device being accessed.

The USB controller also supports connections to Devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

### 20.3.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in Device mode except that the transaction first must be initiated by setting the REQPKT bit in the **USBCSRL0** register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target Device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the **USBCSRL0** register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the **USBXCSRHn** register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in **USBXCSRHn** causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. The AUTOCL and AUTORQ bits can be used with  $\mu$ DMA accesses to perform complete bulk transfers without main processor intervention. When the RXRDY bit is cleared, the controller sends an acknowledge to the Device. When there is a known number of packets to be transferred, the **USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn)** register associated with the endpoint should be configured to the number of packets to be transferred. The USB controller decrements the value in the **USBRQPKTCOUNTn** register following each request. When the **USBRQPKTCOUNTn** value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, **USBRQPKTCOUNTn** should be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the **USBRXMAXPn** register) such as may occur at the end of a bulk transfer.

If the Device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target Device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the **USBCSRL0** register. If the target Device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the **USBCSRL0** register.

### 20.3.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in Device mode. The TXRDY bit in the **USBTXCSRLn** register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the **USBTXCSRHn** register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO. Furthermore, AUTOSET can be used with the  $\mu$ DMA controller to perform complete bulk transfers without software intervention.

If the target Device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target Device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the **USBTXCSRLn** register. If the target Device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target Device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the **USBTXCSRLn** register.

### 20.3.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every

255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a Device is not responding. Isochronous endpoints can be scheduled from every frame to every  $2^{16}$  frames, in powers of 2.

The USB controller maintains a frame counter. If the target Device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target Device is a low-speed device, a *K* state is transmitted on the bus to act as a *keep-alive* to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An isochronous or interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt or isochronous transaction occurs per endpoint every *n* frames, where *n* is the interval set via the **USB Host Transmit Interval Endpoint *n* (USBTXINTERVAL*n*)** or **USB Host Receive Interval Endpoint *n* (USBRXINTERVAL*n*)** register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target Device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target Device before the endpoint times out.

### 20.3.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed Device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding **USB Receive Hub Address Endpoint *n* (USBRXHUBADDR*n*)** and **USB Receive Hub Port Endpoint *n* (USBRXHUBPORT*n*)** or the **USB Transmit Hub Address Endpoint *n* (USBTXHUBADDR*n*)** and **USB Transmit Hub Port Endpoint *n* (USBTXHUBPORT*n*)** registers. In addition, the speed at which the Device operates (full or low) must be recorded in the **USB Type Endpoint 0 (USBTYPE0)** (endpoint 0), **USB Host Configure Transmit Type Endpoint *n* (USBTXTYPE*n*)**, or **USB Host Configure Receive Type Endpoint *n* (USBRXTYPE*n*)** registers for each endpoint that is accessed by the Device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB Devices. To maximize the number of Devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to Device functions must be made following the completion of any on-going transactions on the endpoints affected.

### 20.3.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target Device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

### 20.3.2.7 Host SUSPEND

If the SUSPEND bit in the **USBPOWER** register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20 ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

### 20.3.2.8 USB RESET

If the RESET bit in the **USBPOWER** register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to ensure correct resetting of the target Device. After the CPU has cleared the bit, the USB Host controller starts its frame counter and transaction scheduler.

### 20.3.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the **USB Device Control (USBDEVCTL)** register, enabling the USB controller to wait for a Device to be connected. When a Device is detected, a connect interrupt is generated. The speed of the Device that has been connected can be determined by reading the **USBDEVCTL** register where the FSDEV bit is set for a full-speed Device, and the LSDEV bit is set for a low-speed Device. The USB controller must generate a RESET to the Device, and then the USB Host controller can begin Device enumeration. If the Device is disconnected while a session is in progress, a disconnect interrupt is generated.

## 20.3.3 OTG Mode

To conserve power, the USB On-The-Go (OTG) supplement allows VBUS to only be powered up when required and to be turned off when the bus is not in use. VBUS is always supplied by the A device on the bus. The USB OTG controller determines whether it is the A device or the B device by sampling the ID input from the PHY. This signal is pulled Low when an A-type plug is sensed (signifying that the USB OTG controller should act as the A device) but taken High when a B-type plug is sensed (signifying that the USB controller is a B device). Note that when switching between OTG A and OTG B, the USB controller retains all register contents.

### 20.3.3.1 Starting a Session

When the USB OTG controller is ready to start a session, the SESSION bit must be set in the **USBDEVCTL** register. The USB OTG controller then enables ID pin sensing. The ID input is either taken Low if an A-type connection is detected or High if a B-type connection is detected. The DEV bit in the **USBDEVCTL** register is also set to indicate whether the USB OTG controller has adopted the role of the A device or the B device. The USB OTG controller also provides an interrupt to indicate that ID pin sensing has completed and the mode value in the **USBDEVCTL** register is valid. This interrupt is enabled in the **USBIDVIM** register, and the status is checked in the **USBIDVISC** register. As soon as the USB controller has detected that it is on the A side of the cable, it must enable VBUS power within 100ms or the USB controller reverts to Device mode.

If the USB OTG controller is the A device, then the USB OTG controller enters Host mode (the A device is always the default Host), turns on VBUS, and waits for VBUS to go above the VBUS Valid threshold, as indicated by the VBUS bit in the **USBDEVCTL** register going to 0x3. The USB OTG controller then waits for a peripheral to be connected. When a peripheral is detected, a Connect interrupt is signaled and either the FSDEV or LSDEV bit in the **USBDEVCTL** register is set, depending whether a full-speed or a low-speed peripheral is detected. The USB controller then issues a RESET

to the connected Device. The SESSION bit in the **USBDEVCTL** register can be cleared to end a session. The USB OTG controller also automatically ends the session if babble is detected or if VBUS drops below session valid.

**Note:** The USB OTG controller may not remain in Host mode when connected to high-current devices. Some devices draw enough current to momentarily drop VBUS below the VBUS-valid level causing the controller to drop out of Host mode. The only way to get back into Host mode is to allow VBUS to go below the Session End level. In this situation, the device is causing VBUS to drop repeatedly and pull VBUS back low the next time VBUS is enabled.

In addition, the USB OTG controller may not remain in Host mode when a device is told that it can start using its active configuration. At this point the device starts drawing more current and can also drop VBUS below VBUS valid.

If the USB OTG controller is the B device, then the USB OTG controller requests a session using the session request protocol defined in the USB On-The-Go supplement, that is, it first discharges VBUS. Then when VBUS has gone below the Session End threshold (VBUS bit in the **USBDEVCTL** register goes to 0x0) and the line state has been a single-ended zero for > 2 ms, the USB OTG controller pulses the data line, then pulses VBUS. At the end of the session, the SESSION bit is cleared either by the USB OTG controller or by the application software. The USB OTG controller then causes the PHY to switch out the pull-up resistor on D+, signaling the A device to end the session.

### 20.3.3.2 Detecting Activity

When the other device of the OTG setup wishes to start a session, it either raises VBUS above the Session Valid threshold if it is the A device, or if it is the B device, it pulses the data line then pulses VBUS. Depending on which of these actions happens, the USB controller can determine whether it is the A device or the B device in the current setup and act accordingly. If VBUS is raised above the Session Valid threshold, then the USB controller is the B device. The USB controller sets the SESSION bit in the **USBDEVCTL** register. When RESET signaling is detected on the bus, a RESET interrupt is signaled, which is interpreted as the start of a session.

The USB controller is in Device mode as the B device is the default mode. At the end of the session, the A device turns off the power to VBUS. When VBUS drops below the Session Valid threshold, the USB controller detects this drop and clears the SESSION bit to indicate that the session has ended, causing a disconnect interrupt to be signaled. If data line and VBUS pulsing is detected, then the USB controller is the A device. The controller generates a SESSION REQUEST interrupt to indicate that the B device is requesting a session. The SESSION bit in the **USBDEVCTL** register must be set to start a session.

### 20.3.3.3 Host Negotiation

When the USB controller is the A device, ID is Low, and the controller automatically enters Host mode when a session starts. When the USB controller is the B device, ID is High, and the controller automatically enters Device mode when a session starts. However, software can request that the USB controller become the Host by setting the HOSTREQ bit in the **USBDEVCTL** register. This bit can be set either at the same time as requesting a Session Start by setting the SESSION bit in the **USBDEVCTL** register or at any time after a session has started. When the USB controller next enters SUSPEND mode and if the HOSTREQ bit remains set, the controller enters Host mode and begins host negotiation (as specified in the USB On-The-Go supplement) by causing the PHY to disconnect the pull-up resistor on the D+ line, causing the A device to switch to Device mode and connect its own pull-up resistor. When the USB controller detects this, a Connect interrupt is generated and the RESET bit in the **USBPOWER** register is set to begin resetting the A device. The

USB controller begins this reset sequence automatically to ensure that RESET is started as required within 1 ms of the A device connecting its pull-up resistor. The main processor should wait at least 20 ms, then clear the RESET bit and enumerate the A device.

When the USB OTG controller B device has finished using the bus, the USB controller goes into SUSPEND mode by setting the SUSPEND bit in the **USBPOWER** register. The A device detects this and either terminates the session or reverts to Host mode. If the A device is USB OTG controller, it generates a Disconnect interrupt.

## 20.3.4 DMA Operation

The USB peripheral provides an interface connected to the  $\mu$ DMA controller with separate channels for 3 transmit endpoints and 3 receive endpoints. Software selects which endpoints to service with the  $\mu$ DMA channels using the **USB DMA Select (USBDMASEL)** register. The  $\mu$ DMA operation of the USB is enabled through the **USBTXCSRHn** and **USBRXCSRHn** registers, for the TX and RX channels respectively. When  $\mu$ DMA operation is enabled, the USB asserts a  $\mu$ DMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The  $\mu$ DMA channel must be configured to operate in Basic mode, and the size of the  $\mu$ DMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using  $\mu$ DMA must be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the  $\mu$ DMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If the DMAMOD bit in the **USBTXCSRHn/USBRXCSRHn** register is clear, an interrupt is generated after every packet is transferred, but the  $\mu$ DMA continues transferring data. If the DMAMOD bit is set, an interrupt is generated only when the entire  $\mu$ DMA transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and the  $\mu$ DMA is enabled, the USB interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

Care must be taken when using the  $\mu$ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of value of the MAXLOAD field in the **USBRXCSRHn** register. The RXRDY bit is cleared as follows.

**Table 20-3. Remainder (MAXLOAD/4)**

| Value | Description        |
|-------|--------------------|
| 0     | MAXLOAD = 64 bytes |
| 1     | MAXLOAD = 61 bytes |
| 2     | MAXLOAD = 62 bytes |
| 3     | MAXLOAD = 63 bytes |

**Table 20-4. Actual Bytes Read**

| Value | Description |
|-------|-------------|
| 0     | MAXLOAD     |
| 1     | MAXLOAD+3   |
| 2     | MAXLOAD+2   |
| 3     | MAXLOAD+1   |

Table 20-5. Packet Sizes That Clear RXRDY

| Value | Description                              |
|-------|------------------------------------------|
| 0     | MAXLOAD, MAXLOAD-1, MAXLOAD-2, MAXLOAD-3 |
| 1     | MAXLOAD                                  |
| 2     | MAXLOAD, MAXLOAD-1                       |
| 3     | MAXLOAD, MAXLOAD-1, MAXLOAD-2            |

To enable DMA operation for the endpoint receive channel, the DMAEN bit of the **USBXCSRHn** register should be set. To enable DMA operation for the endpoint transmit channel, the DMAEN bit of the **USBTXCSRHn** register must be set.

See “Micro Direct Memory Access (μDMA)” on page 365 for more details about programming the μDMA controller.

## 20.4 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled via the **RCGC2** register (see page 285). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module (see page 285). To find out which GPIO port to enable, refer to Table 23-4 on page 1165. Configure the PMCN fields in the **GPIOPCTL** register to assign the USB signals to the appropriate pins (see page 464 and Table 23-5 on page 1172).

The initial configuration in all cases requires that the processor enable the USB controller and USB controller's physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY. To ensure that voltage is not supplied to the bus incorrectly, the external power control signal, USB0EPEN, should be negated on start up by configuring the USB0EPEN and USB0PFLT pins to be controlled by the USB controller and not exhibit their default GPIO behavior.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

### 20.4.1 Pin Configuration

When using the Device controller portion of the USB controller in a system that also provides Host functionality, the power to VBUS must be disabled to allow the external Host controller to supply power. Usually, the USB0EPEN signal is used to control the external regulator and should be negated to avoid having two devices driving the USB0VBUS power pin on the USB connector.

When the USB controller is acting as a Host, it is in control of two signals that are attached to an external voltage supply that provides power to VBUS. The Host controller uses the USB0EPEN signal to enable or disable power to the USB0VBUS pin on the USB connector. An input pin, USB0PFLT, provides feedback when there has been a power fault on VBUS. The USB0PFLT signal can be

configured to either automatically negate the USB0EPEN signal to disable power, and/or it can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both USB0EPEN and USB0PFLT are fully configurable in the USB controller. The controller also provides interrupts on Device insertion and removal to allow the Host controller code to respond to these external events.

## 20.4.2 Endpoint Configuration

To start communication in Host or Device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a Device. In Device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because it is a fixed-function, fixed-FIFO-size endpoint. In Device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In Device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, interrupt or isochronous mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to 1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a Device, the USB Device controller's soft connect must be enabled when the Device is ready to start communications, indicating to the Host controller that the Device is ready to start the enumeration process. If operating as a Host controller, the Device soft connect must be disabled and power must be provided to VBUS via the USB0EPEN signal.

## 20.5 Register Map

Table 20-6 on page 1007 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 285). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Table 20-6. Universal Serial Bus (USB) Controller Register Map**

| Offset | Name     | Type | Reset  | Description                   | See page |
|--------|----------|------|--------|-------------------------------|----------|
| 0x000  | USBFADDR | R/W  | 0x00   | USB Device Functional Address | 1019     |
| 0x001  | USBPOWER | R/W  | 0x20   | USB Power                     | 1020     |
| 0x002  | USBTXIS  | RO   | 0x0000 | USB Transmit Interrupt Status | 1023     |
| 0x004  | USBRXIS  | RO   | 0x0000 | USB Receive Interrupt Status  | 1025     |
| 0x006  | USBTXIE  | R/W  | 0xFFFF | USB Transmit Interrupt Enable | 1027     |

Table 20-6. Universal Serial Bus (USB) Controller Register Map (*continued*)

| Offset | Name         | Type | Reset       | Description                                            | See page |
|--------|--------------|------|-------------|--------------------------------------------------------|----------|
| 0x008  | USBRXIE      | R/W  | 0xFFFE      | USB Receive Interrupt Enable                           | 1029     |
| 0x00A  | USBIS        | RO   | 0x00        | USB General Interrupt Status                           | 1031     |
| 0x00B  | USBIE        | R/W  | 0x06        | USB Interrupt Enable                                   | 1034     |
| 0x00C  | USBFRAME     | RO   | 0x0000      | USB Frame Value                                        | 1037     |
| 0x00E  | USBEPIDX     | R/W  | 0x00        | USB Endpoint Index                                     | 1038     |
| 0x00F  | USBTEST      | R/W  | 0x00        | USB Test Mode                                          | 1039     |
| 0x020  | USBFIFO0     | R/W  | 0x0000.0000 | USB FIFO Endpoint 0                                    | 1041     |
| 0x024  | USBFIFO1     | R/W  | 0x0000.0000 | USB FIFO Endpoint 1                                    | 1041     |
| 0x028  | USBFIFO2     | R/W  | 0x0000.0000 | USB FIFO Endpoint 2                                    | 1041     |
| 0x02C  | USBFIFO3     | R/W  | 0x0000.0000 | USB FIFO Endpoint 3                                    | 1041     |
| 0x030  | USBFIFO4     | R/W  | 0x0000.0000 | USB FIFO Endpoint 4                                    | 1041     |

## 20.6 Register Descriptions

The LM3S9B90 USB controller has On-The-Go (OTG) capabilities as specified in the USB0 bit field in the **DC6** register (see page 257).

**OTG B /  
Device**

This icon indicates that the register is used in OTG B or Device mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode.

**OTG A /  
Host**

This icon indicates that the register is used in OTG A or Host mode. Some registers are used for both Host and Device mode and may have different bit definitions depending on the mode. The USB controller is in OTG B or Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

**OTG**

This icon indicates that the register is used for OTG-specific functions such as ID detection and negotiation. Once OTG negotiation is complete, then the USB controller registers are used according to their Host or Device mode meanings depending on whether the OTG negotiations made the USB controller OTG A (Host) or OTG B (Device).

**Register 1: USB Device Functional Address (USBFADDR), offset 0x000****OTG B /  
Device**

**USBFADDR** is an 8-bit register that contains the 7-bit address of the Device part of the transaction.

When the USB controller is being used in Device mode (the HOST bit in the **USBDEVCTL** register is clear), this register must be written with the address received through a SET\_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

**Important:** See the section called “Setting the Device Address” on page 998 for special considerations when writing this register.

## USB Device Functional Address (USBFADDR)

**Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002****Important:** This register is read-sensitive. See the register description for details.**OTG A /  
Host**

**USBTXIS** is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–15. The meaning of the EPn bits in this register is based on the mode of the device. The EP1 through EP15 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints. The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt.

**OTG B /  
Device**

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

**Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006****OTG A /  
Host**

**USBTXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBTXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared, the interrupt in the **USBTXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

**OTG B /

|           |      |      |       | 1 An interrupt is sent to the interrupt controller when the EP0 bit in the <b>USBTXIS</b> register is set. |
|           |      |      |       | 0 The EP0 transmit and receive interrupt is suppressed and not sent to the interrupt controller.           |

**Register 6: USB Receive Interrupt Enable (USBRXIE), offset 0x008****OTG A /  
Host**

**USBRXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in the **USBRXIS** register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the **USBRXIS** register is set. When a bit is cleared, the interrupt in the **USBRXIS** register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

**OTG B /  
Device**

**Register 8: USB Interrupt Enable (USBIE), offset 0x00B**

OTG A /  
Host

**USBIE** is an 8-bit register that provides interrupt enable bits for each of the interrupts in **USBIS**. At reset interrupts 1 and 2 are enabled in Device mode.

OTG B /  
Device

| Bit/Field | Name   | Type | Reset | Description     |
|-----------|--------|------|-------|-----------------|
| 7         | FORCEH | R/W  | 0     | Force Host Mode |

**Value Description**

- 1 Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.

- 0 No effect.

While in this mode, status of the bus connection may be read using the DEV bit of the **USBDEVCTL** register. The operating speed is determined from the FORCEFS bit.

---

**Important:** This register is read-sensitive. See the register description for details.

---

**OTG A /  
Host**

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

**OTG B /  
Device**

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see the section called “Single-Packet Buffering” on page 996). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–15, the associated FIFO is completely flushed.

**Register 28: USB Device Control (USBDEVCTL), offset 0x060****OTG A /  
Host**

**USBDEVCTL** is an 8-bit register used for controlling and monitoring the USB VBUS line. If the PHY is suspended, no PHY clock is received and the VBUS is not sampled. In addition, in Host mode, **USBDEVCTL** provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

**USB Device Control (USBDEVCTL)**

Base 0x4005.0000

Offset 0x060

**Register 29: USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ), offset 0x062****Register 30: USB Receive Dynamic FIFO Sizing (USBRXFIFOSZ), offset 0x063****OTG A /  
Host**

These 8-bit registers allow the selected TX/RX endpoint FIFOs to be dynamically sized. **USBEPIDX** is used to configure each transmit endpoint's FIFO size.

**USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ)**

Base 0x4005.0000

Offset 0x062

Type R/W, reset 0x00

**OTG B /  
Device**

**Register 31: USB Transmit FIFO Start Address (USBTXFIFOADD), offset 0x064****Register 32: USB Receive FIFO Start Address (USBRXFIFOADD), offset 0x066**OTG A /  
Host

**USBTXFIFOADD** and **USBRXFIFOADD** are 16-bit registers that control the start address of the selected transmit and receive endpoint FIFOs.

USB Transmit FIFO Start Address (USBTXFIFOADD)

Base 0x4005.0000

Offset 0x064

Type R/W, reset 0x0000

OTG B /  
Device

| Bit/Field | Name     | Type | Reset | Description                                                                                                                                                                                   |

**USBRXHUBADDR<sub>n</sub>** is an 8-bit read/write register that, like **USBRXHUBPORT<sub>n</sub>**, only must be written when a full- or low-speed Device is connected to receive endpoint EP<sub>n</sub> via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

**Note:** **USBTXHUBADDR0** is used for both receive and transmit for endpoint 0.

**Register 144: USB Maximum Transmit Data Endpoint 15 (USBTXMAXP15), offset 0x1F0**

**OTG A /  
Host**

The **USBTXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

**OTG B /  
Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in **USBTXCSRLn**) after writing the new value to this register.

**Note:** **USBTXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic Mode.

|   |       |     |   |             |
|---|-------|-----|---|-------------|
| 7 | NAKTO | R/W | 0 | NAK Timeout |
|---|-------|-----|---|-------------|

Value Description

0 No timeout.

1 Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the **USBNAKLMT** register.

Software must clear this bit to allow the endpoint to continue.

|   |        |     |   |               |
|---|--------|-----|---|---------------|
| 6 | STATUS | R/W | 0 | STATUS Packet |
|---|--------|-----|---|---------------|

Value Description

0 No transaction.

1 Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set.

Setting this bit ensures that the DT bit is set in the **USBCSRH0** register so that a DATA1 packet is used for the STATUS stage transaction. This bit is automatically cleared when the STATUS stage is over.

|   |        |     |   |                |
|---|--------|-----|---|----------------|
| 5 | REQPKT | R/W | 0 | Request Packet |
|---|--------|-----|---|----------------|

Value Description

0 No request.

1 Requests an IN transaction.

This bit is cleared when the RXRDY bit is set.

| Bit/Field | Name  | Type | Reset | Description |
|-----------|-------|------|-------|-------------|
| 0         | FLUSH | R/W  | 0     | Flush FIFO  |

## Value Description

0 No effect.

1 Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.

This bit is automatically cleared after the flush is performed.

**Important:** This bit should only be set when TXRDY is clear and RXRDY is set. At other times, it may cause data to be corrupted.

## Value Description

0 No effect.

1 Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.

This bit is automatically cleared after the flush is performed.

**Important:** This bit should only be set when TXRDY is clear and RXRDY is set. At other times, it may cause data to be corrupted.

**Register 147: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108****OTG A /  
Host**

**USBCOUNT0** is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

**Register 149: USB NAK Limit (USBNAKLMT), offset 0x10B****OTG A /  
Host**

**USBNAKLMT** is an 8-bit register that sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their **USBTXINTERVALn** and **USBRXINTERVALn** registers.)

The number of frames selected is  $2^{(m-1)}$  (where  $m$  is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

**Note:** A value of 0 or 1 disables the NAK timeout function.

**USB NAK Limit (USBNAKLMT)**

OTG A /  
Host

**USBTXCSRHn** is an 8-bit register that provides additional control for transfers through the currently selected transmit endpoint.

**Register 194: USB Maximum Receive Data Endpoint 15 (USBRXMAXP15), offset 0x1F4**

**OTG A /  
Host**

The **USBRXMAXP<sub>n</sub>** is a 16-bit register which defines the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

**OTG B /  
Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operations.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the receive endpoint, and must not exceed half the FIFO size if double-buffering is required.

**Note:** **USBRXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Basic mode.

|---|--------|-----|---|------------|
| 7 | AUTOCL | R/W | 0 | Auto Clear |
|---|--------|-----|---|------------|

Value Description

0 No effect.

1 Enables the RXRDY bit to be automatically cleared when a packet of **USBRXMAXPn** bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using  $\mu$ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the value of the MAXLOAD field in the **USBRXMAXPn** register, see "DMA Operation" on page 1005.

|   |        |     |   |              |
|---|--------|-----|---|--------------|
| 6 | AUTORQ | R/W | 0 | Auto Request |
|---|--------|-----|---|--------------|

Value Description

0 No effect.

1 Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared.

**Note:** This bit is automatically cleared when a short packet is received.

|   |       |     |   |                    |
|---|-------|-----|---|--------------------|
| 5 | DMAEN | R/W | 0 | DMA Request Enable |
|---|-------|-----|---|--------------------|

Value Description

0 Disables the  $\mu$ DMA request for the receive endpoint.1 Enables the  $\mu$ DMA request for the receive endpoint.

**Note:** 3 TX and 3 RX endpoints can be connected to the  $\mu$ DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the **USB DMA Select (USBDMASEL)** register must be programmed correspondingly.

|   |        |    |   |           |
|---|--------|----|---|-----------|
| 4 | PIDERR | RO | 0 | PID Error |
|---|--------|----|---|-----------|

Value Description

0 No error.

1 Indicates a PID error in the received packet of an isochronous transaction.

This bit is ignored in bulk or interrupt transactions.

OTG A /  
Host

**Note:** The value returned changes as the FIFO is unloaded and is only valid while the RXRDY bit in the **USBXCSRLn** register is set.

**USBXCOUNTn** is a 16-bit read-only register that holds the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

**Register 253: USB Host Transmit Configure Type Endpoint 14 (USBTXTYPE14), offset 0x1EA**

**Register 254: USB Host Transmit Configure Type Endpoint 15 (USBTXTYPE15), offset 0x1FA**

**OTG A /  
Host**

**USBTXTYPE<sub>n</sub>** is an 8-bit register that must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected transmit endpoint, and its operating speed.

## USB Host Transmit Configure Type Endpoint 1 (USBTXTYPE1)

Base 0x4005.0000

Offset 0x11A

Type R/W, reset 0x00

Host**

**USBTXINTERVAL<sub>n</sub>** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBTXINTERVAL<sub>n</sub>** register value defines a number of frames, as follows:

| Transfer Type | Speed                   | Valid values (m) | Interpretation                                                                            |
|---------------|-------------------------|------------------|-------------------------------------------------------------------------------------------|
| Interrupt     | Low-Speed or Full-Speed | 0x01 – 0xFF      | The polling interval is $m$ frames.                                                       |
| Isochronous   | Full-Speed              | 0x01 – 0x10      | The polling interval is $2^{(m-1)}$ frames.                                               |
| Bulk          | Full-Speed              | 0x02 – 0x10      | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

## USB Host Transmit Interval Endpoint 1 (USBTXINTERVAL1)

Base 0x4005.0000

Offset 0x11B

Type R/W, reset 0x00

| Bit/Field | Name            | Type | Reset | Description            |
|-----------|-----------------|------|-------|------------------------|
| 7:0       | TXPOLL / NAKLMT | R/W  | 0x00  | TX Polling / NAK Limit |

The polling interval for interrupt/isochronous transfers; the NAK limit for bulk transfers. See table above for valid entries; other values are reserved.

**OTG A /  
Host**

**USBRTYPE<sub>n</sub>** is an 8-bit register that must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected receive endpoint, and its operating speed.

**OTG A /  
Host**

**USBRXINTERVAL<sub>n</sub>** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected receive endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBRXINTERVAL<sub>n</sub>** register value defines a number of frames, as follows:

| Transfer Type | Speed                   | Valid values (m) | Interpretation                              |
|---------------|-------------------------|------------------|---------------------------------------------|
| Interrupt     | Low-Speed or Full-Speed | 0x01 – 0xFF      | The polling interval is <i>m</i> frames.    |
| Isochronous   | Full-Speed              | 0x01 – 0x10      | The polling interval is $2^{(m-1)}$ frames. |

| Transfer Type | Speed      | Valid values (m) | Interpretation                                                                            |
|---------------|------------|------------------|-------------------------------------------------------------------------------------------|
| Bulk          | Full-Speed | 0x02 – 0x10      | The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function. |

**Register 314: USB Request Packet Count in Block Transfer Endpoint 15 (USBRQPKTCOUNT15), offset 0x33C**

**OTG A /  
Host**

This 16-bit read/write register is used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint n. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the **USBRXCSRHn** register has been set. See “IN Transactions as a Host” on page 1001.

**Note:** Multiple packets combined into a single bulk packet within the FIFO count as one packet.

**Register 317: USB External Power Control (USBEPD), offset 0x400****OTG A /  
Host**

This 32-bit register specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

## Value Description

1 A Power Fault status has been detected.

0 An interrupt has not occurred.

This bit is cleared by writing a 1 to the PF bit in the **USBEPKISC** register.

**Register 319: USB External Power Control Interrupt Mask (USBEPICIM), offset 0x408****OTG A /  
Host**

This 32-bit register specifies the interrupt mask of the two-pin external power interface.

### Value Description

- 1 The PF bits in the **USBEPICRIS** and **USBEPICIM** registers are set, providing an interrupt to the interrupt controller.
- 0 No interrupt has occurred or the interrupt is masked.

This bit is cleared by writing a 1. Clearing this bit also clears the PF bit in the **USBEPICRIS** register.

**Register 321: USB Device RESUME Raw Interrupt Status (USBDRRIS), offset 0x410****OTG A /  
Host**

The **USBDRRIS** 32-bit register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

**Value Description**

1 A RESUME status has been detected.

0 An interrupt has not occurred.

This bit is cleared by writing a 1 to the RESUME bit in the **USBDRISC** register.

**Register 322: USB Device RESUME Interrupt Mask (USBDRIM), offset 0x414****OTG A /  
Host**

The **USBDRIM** 32-bit register is the masked interrupt status register. On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

## Value Description

- 1 The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the **USBIS** register is set).
- 0 A detected RESUME does not affect the interrupt status.

## Register 323: USB Device RESUME Interrupt Status and Clear (USBDRISC), offset 0x418

OTG A /  
Host

The **USBDRISC** 32-bit register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

### Value Description

- |   |                                                                                                                                   |
|---|-----------------------------------------------------------------------------------------------------------------------------------|
| 1 | The RESUME bits in the <b>USBDRRIS</b> and <b>USBDRCIM</b> registers are set, providing an interrupt to the interrupt controller. |
| 0 | No interrupt has occurred or the interrupt is masked.                                                                             |

This bit is cleared by writing a 1. Clearing this bit also clears the RESUME bit in the **USBDRCRIS** register.

**Register 324: USB General-Purpose Control and Status (USBGPCS), offset 0x41C****OTG A /  
Host****OTG B /  
Device****USBGPCS** provides the state of the internal ID signal.

**Note:** When used in OTG mode, USB0VBUS and USB0ID do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the USB0VBUS and USB0ID inputs to fixed levels internally, freeing the PB0 and PB1 pins for GPIO use. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

**Register 325: USB VBUS Droop Control (USBVDC), offset 0x430****OTG A /  
Host**

This 32-bit register enables a controlled masking of VBUS to compensate for any in-rush current by a Device that is connected to the Host controller. The in-rush current can cause VBUS to droop, causing the USB controller's behavior to be unexpected. The USB Host controller allows VBUS to fall lower than the VBUS Valid level (4.75 V) but not below AValid (2.0 V) for 65 microseconds without signaling a VBUSERR interrupt in the controller. Without this, any glitch on VBUS would force the USB Host controller to remove power from VBUS and then re-enumerate the Device.

## 21 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 1131 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris<sup>®</sup> LM3S9B90 microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

Figure 21-1. Analog Comparator Module Block Diagram

## 21.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 446) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 464) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 423.

Table 21-1. Analog Comparators Signals (100LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                         |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------|
| C0+      | 90         | PB6                      | I        | Analog                   | Analog comparator 0 positive input. |
| C0-      | 92         | PB4                      | I        | Analog                   | Analog comparator 0 negative input. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 21.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$V_{IN-} < V_{IN+}$ ,  $V_{OUT} = 1$

$V_{IN-} > V_{IN+}$ ,  $V_{OUT} = 0$

As shown in Figure 21-2 on page 1133, the input source for VIN- is an external input, Cn-. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference,  $V_{\text{IREF}}$ .

**Figure 21-2. Structure of Comparator Unit**

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the ISEN bit in the **ACCTL** register. The output may also be used to drive an external pin, Co or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

### 21.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 21-3 on page 1133. The internal reference is controlled by a single configuration register (**ACREFCTL**).

**Figure 21-3. Comparator Internal Reference Structure**

The internal reference can be programmed in one of two modes (low range or high range) depending on the RNG bit in the **ACREFCTL** register. When RNG is clear, the internal reference is in high-range mode, and when RNG is set the internal reference is in low-range mode.

In each range, the internal reference,  $V_{IREF}$ , has 16 pre-programmed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the VREF field in the **ACREFCTL** register.

In the high-range mode, the  $V_{IREF}$  threshold voltages start at the ideal high-range starting voltage of  $V_{DDA}/3.875$  and increase in ideal constant voltage steps of  $V_{DDA}/31$ .

In the low-range mode, the  $V_{IREF}$  threshold voltages start at 0V and increase in ideal constant voltage steps of  $V_{DDA}/23$ . The ideal  $V_{IREF}$  step voltages for each mode and their dependence on the RNG and VREF fields are summarized in Table 21-3 on page 1134.

**Table 21-3. Internal Reference Voltage and ACREFTL Field Values**

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                                                                                                                                                       |
|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN Bit Value      | RNG Bit Value |                                                                                                                                                                                                                                                          |
| EN=0              | RNG=X         | 0 V (GND) for any value of VREF. It is recommended that RNG=1 and VREF=0 to minimize noise on the reference ground.                                                                                                                                      |
| EN=1              | RNG=0         | <p>Total resistance in ladder is 31 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{(VREF + 8)}{31}$ $V_{IREF} = 0.85 + 0.106 \times VREF$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p> |
|                   | RNG=1         | <p>Total resistance in ladder is 23 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{VREF}{23}$ $V_{IREF} = 0.143 \times VREF$ <p>The range of internal reference for this mode is 0-2.152 V.</p>                |

## 21.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module (see page 276).
2. Enable the clock to the appropriate GPIO modules via the **RCGC2** register (see page 285). To find out which GPIO ports to enable, refer to Table 23-5 on page 1172.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 23-4 on page 1165.
4. Configure the PMCN fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 464 and Table 23-5 on page 1172).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value of 0x0000.040C.
7. Delay for 10  $\mu$ s.
8. Read the comparator output value by reading the **ACSTATn** register's OVAL value.

Change the level of the comparator negative input signal C- to see the OVAL value change.

## 21.5 Register Map

Table 21-4 on page 1135 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 276). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 21-4. Analog Comparators Register Map**

| Offset | Name     | Type  | Reset       | Description                                 | See page |

**Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x008**

This register provides the interrupt enable for the comparators.

**Analog Comparator Interrupt Enable (ACINTEN)**

Base 0x4003.C000

Offset 0x008

Type R/W, reset 0x0000.0000

| 0         | A comparator 0 interrupt does not affect the interrupt status.             |      |       |                                                                                                                                                                                                                                                                                             |       |             |   |                                                                            |   |                                                                |

## Register 4: Analog Comparator Reference Voltage Control (ACREFCTL), offset 0x010

This register specifies whether the resistor ladder is powered on as well as the range and tap.

### Analog Comparator Reference Voltage Control (ACREFCTL)

Base 0x4003.C000

Offset 0x010

Type R/W, reset 0x0000.0000

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                            |       |             |     |                                                            |     |                                                                                |     |             |     |             |

## 22 Pin Diagram

The LM3S9B90 microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 23-5 on page 1172.

Figure 22-1. 100-Pin LQFP Package Pin Diagram

Figure 22-2. 108-Ball BGA Package Pin Diagram (Top View)

## 23 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 462) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 446) must be set. Further pin muxing options are provided through the PMCx bit field in the **GPIOPCTL** register (see page 464), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 23-1. GPIO Pins With Default Alternate Functions**

| GPIO Pin | Default State     | GPIOAFSEL Bit | GPIOPCTL PMCx Bit Field |
|----------|-------------------|---------------|-------------------------|
| PA[1:0]  | UART0             | 0             | 0x1                     |
| PA[5:2]  | SSI0              | 0             | 0x1                     |
| PB[3:2]  | I <sup>2</sup> C0 | 0             | 0x1                     |
| PC[3:0]  | JTAG/SWD          | 1             | 0x3                     |

Table 23-2 on page 1147 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 23-3 on page 1156 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMCx bit field in the **GPIOPCTL** register.

Table 23-4 on page 1165 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 23-5 on page 1172 lists the GPIO pins and their analog and digital alternate functions. The AINx and VREFA analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry (C0-, C0+, C1-, C1+, C2-, C2+, USB0VBUS, USB0ID). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMCx bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 23-6 on page 1175 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Stellaris® Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

## 23.1 100-Pin LQFP Package Pin Tables

### 23.1.1 Signals by Pin Number

Table 23-2. Signals by Pin Number

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |

|            | C1o      | O        | TTL                      | Analog comparator 1 output.                                                                                                                                                                                                                                                                                                              |
|            | U1CTS    | I        | TTL                      | UART module 1 Clear To Send modem flow control input signal.                                                                                                                                                                                                                                                                             |
| 3          | VDDA     | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 25-2 on page 1213, regardless of system implementation. |
| 4          | GNDA     | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
| 5          | PE5      | I/O      | TTL                      | GPIO port E bit 5.                                                                                                                                                                                                                                                                                                                       |
|            | AIN2     | I        | Analog                   | Analog-to-digital converter input 2.                                                                                                                                                                                                                                                                                                     |
|            | CCP5     | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                                                                                                                                                                                                                                                                   |
|            | I2S0TXSD | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit data.                                                                                                                                                                                                                                                                                                 |
| 6          | PE4      | I/O      | TTL                      | GPIO port E bit 4.                                                                                                                                                                                                                                                                                                                       |
|            | AIN3     | I        | Analog                   | Analog-to-digital converter input 3.                                                                                                                                                                                                                                                                                                     |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                                                                                                   |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                                                                                                                                                                                                                                                   |
|            | I2S0TXWS | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit word select.                                                                                                                                                                                                                                                                                          |
|            | U2Tx     | O        | TTL                      | UART module 2 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                                                                              |
| 7          | LDO      | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 µF or greater. The LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).                                                                                            |
| 8          | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
| 9          | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                 |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                           |
|------------|-----------|----------|--------------------------|---------------------------------------------------------------------------------------|
| 10         | PD0       | I/O      | TTL                      | GPIO port D bit 0.                                                                    |
|            | AIN15     | I        | Analog                   | Analog-to-digital converter input 15.                                                 |
|            | CAN0Rx    | I        | TTL                      | CAN module 0 receive.                                                                 |
|            | CCP6      | I/O      | TTL                      | Capture/Compare/PWM 6.                                                                |
|            | I2S0RXSCK | I/O      | TTL                      | I <sup>2</sup> S module 0 receive clock.                                              |
|            | U1CTS     | I        | TTL                      | UART module 1 Clear To Send modem flow control input signal.                          |
|            | U1Rx      | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.            |
| 11         | U2Rx      | I        | TTL                      | UART module 2 receive. When in IrDA mode, this signal has IrDA modulation.            |
|            | PD1       | I/O      | TTL                      | GPIO port D bit 1.                                                                    |
|            | AIN14     | I        | Analog                   | Analog-to-digital converter input 14.                                                 |
|            | CAN0Tx    | O        | TTL                      | CAN module 0 transmit.                                                                |
|            | CCP2      | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                |
|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                |
|            | I2S0RXWS  | I/O      | TTL                      | I <sup>2</sup> S module 0 receive word select.                                        |
| 12         | U1DCD     | I        | TTL                      | UART module 1 Data Carrier Detect modem status input signal.                          |
|            | U1Tx      | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.           |
|            | U2Tx      | O        | TTL                      | UART module 2 transmit. When in IrDA mode, this signal has IrDA modulation.           |
|            | PD2       | I/O      | TTL                      | GPIO port D bit 2.                                                                    |
|            | AIN13     | I        | Analog                   | Analog-to-digital converter input 13.                                                 |
|            | CCP5      | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                |
|            | CCP6      | I/O      | TTL                      | Capture/Compare/PWM 6.                                                                |
| 13         | EPI0S20   | I/O      | TTL                      | EPI module 0 signal 20.                                                               |
|            | U1Rx      | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.            |
|            | PD3       | I/O      | TTL                      | GPIO port D bit 3.                                                                    |
|            | AIN12     | I        | Analog                   | Analog-to-digital converter input 12.                                                 |
|            | CCP0      | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                |
|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                |
| 14         | EPI0S21   | I/O      | TTL                      | EPI module 0 signal 21.                                                               |
|            | U1Tx      | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.           |
|            | PJ0       | I/O      | TTL                      | GPIO port J bit 0.                                                                    |
| 15         | EPI0S16   | I/O      | TTL                      | EPI module 0 signal 16.                                                               |
|            | I2C1SCL   | I/O      | OD                       | I <sup>2</sup> C module 1 clock.                                                      |
| 16         | PH7       | I/O      | TTL                      | GPIO port H bit 7.                                                                    |
|            | EPI0S27   | I/O      | TTL                      | EPI module 0 signal 27.                                                               |
|            | SSI1Tx    | O        | TTL                      | SSI module 1 transmit.                                                                |
| 16         | XTALPPHY  | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input or external clock reference input. |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                 |
|------------|----------|----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17         | XTALNPHY | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output. Leave this pin unconnected when using a single-ended 25-MHz clock input connected to the XTALPPHY pin. |
| 18         | PG1      | I/O      | TTL                      | GPIO port G bit 1.                                                                                                                                          |
|            | EPI0S14  | I/O      | TTL                      | EPI module 0 signal 14.                                                                                                                                     |
|            | I2C1SDA  | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                                                                             |
|            | U2Tx     | O        | TTL                      | UART module 2 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                 |
| 19         | PG0      | I/O      | TTL                      | GPIO port G bit 0.                                                                                                                                          |
|            | EPI0S13  | I/O      | TTL                      | EPI module 0 signal 13.                                                                                                                                     |
|            | I2C1SCL  | I/O      | OD                       | I <sup>2</sup> C module 1 clock.                                                                                                                            |
|            | U2Rx     | I        | TTL                      | UART module 2 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                  |
|            | USB0EPEN | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                            |
| 20         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                     |
| 21         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                    |
| 22         | PC7      | I/O      | TTL                      | GPIO port C bit 7.                                                                                                                                          |
|            | C1o      | O        | TTL                      | Analog comparator 1 output.                                                                                                                                 |
|            | C2-      | I        | Analog                   | Analog comparator 2 negative input.                                                                                                                         |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                      |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                                                                                      |
|            | EPI0S5   | I/O      | TTL                      | EPI module 0 signal 5.                                                                                                                                      |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                 |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                   |
| 23         | PC6      | I/O      | TTL                      | GPIO port C bit 6.                                                                                                                                          |
|            | C2+      | I        | Analog                   | Analog comparator 2 positive input.                                                                                                                         |
|            | C2o      | O        | TTL                      | Analog comparator 2 output.                                                                                                                                 |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                      |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                                                                      |
|            | EPI0S4   | I/O      | TTL                      | EPI module 0 signal 4.                                                                                                                                      |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                  |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                   |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name   | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                      |
|------------|------------|----------|--------------------------|--------------------------------------------------------------------------------------------------|
| 24         | PC5        | I/O      | TTL                      | GPIO port C bit 5.                                                                               |
|            | C0o        | O        | TTL                      | Analog comparator 0 output.                                                                      |
|            | C1+        | I        | Analog                   | Analog comparator 1 positive input.                                                              |
|            | C1o        | O        | TTL                      | Analog comparator 1 output.                                                                      |
|            | CCP1       | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                           |
|            | CCP3       | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                           |
|            | EPI0S3     | I/O      | TTL                      | EPI module 0 signal 3.                                                                           |
|            | USB0EPEN   | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus. |
| 25         | PC4        | I/O      | TTL                      | GPIO port C bit 4.                                                                               |
|            | CCP1       | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                           |
|            | CCP2       | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                           |
|            | CCP4       | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                           |
|            | CCP5       | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                           |
|            | EPI0S2     | I/O      | TTL                      | EPI module 0 signal 2.                                                                           |
| 26         | PA0        | I/O      | TTL                      | GPIO port A bit 0.                                                                               |
|            | I2C1SCL    | I/O      | OD                       | I <sup>2</sup> C module 1 clock.                                                                 |
|            | U0Rx       | I        | TTL                      | UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.                       |
|            | U1Rx       | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                       |
| 27         | PA1        | I/O      | TTL                      | GPIO port A bit 1.                                                                               |
|            | I2C1SDA    | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                  |
|            | U0Tx       | O        | TTL                      | UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.                      |
|            | U1Tx       | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                      |
| 28         | PA2        | I/O      | TTL                      | GPIO port A bit 2.                                                                               |
|            | I2S0RXSD   | I/O      | TTL                      | I <sup>2</sup> S module 0 receive data.                                                          |
|            | SSI0C1k    | I/O      | TTL                      | SSI module 0 clock                                                                               |
| 29         | PA3        | I/O      | TTL                      | GPIO port A bit 3.                                                                               |
|            | I2S0RXMCLK | I/O      | TTL                      | I <sup>2</sup> S module 0 receive master clock.                                                  |
|            | SSI0Fss    | I/O      | TTL                      | SSI module 0 frame signal                                                                        |
| 30         | PA4        | I/O      | TTL                      | GPIO port A bit 4.                                                                               |
|            | CAN0Rx     | I        | TTL                      | CAN module 0 receive.                                                                            |
|            | I2S0TXSCK  | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit clock.                                                        |
|            | SSI0Rx     | I        | TTL                      | SSI module 0 receive                                                                             |
| 31         | PA5        | I/O      | TTL                      | GPIO port A bit 5.                                                                               |
|            | CAN0Tx     | O        | TTL                      | CAN module 0 transmit.                                                                           |
|            | I2S0TXWS   | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit word select.                                                  |
|            | SSI0Tx     | O        | TTL                      | SSI module 0 transmit                                                                            |
| 32         | VDD        | -        | Power                    | Positive supply for I/O and some logic.                                                          |
| 33         | ERBIAS     | O        | Analog                   | 12.4-kΩ resistor (1% precision) used internally for Ethernet PHY.                                |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                               |
|------------|----------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 43         | TX0P     | O        | TTL                      | TX0P of the Ethernet PHY.                                                                                                                                                                                                                                                 |
| 44         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                   |
| 45         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                  |
| 46         | TX0N     | O        | TTL                      | TX0N of the Ethernet PHY.                                                                                                                                                                                                                                                 |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name   | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                    |
|------------|------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 47         | PF0        | I/O      | TTL                      | GPIO port F bit 0.                                                                                                                                                                                                                             |
|            | CAN1Rx     | I        | TTL                      | CAN module 1 receive.                                                                                                                                                                                                                          |
|            | I2S0TXSD   | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit data.                                                                                                                                                                                                       |
|            | U1DSR      | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                                                                                                                                                                                        |
| 48         | OSC0       | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                                                                                                                                                                            |
| 49         | OSC1       | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                                      |
| 50         | WAKE       | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                               |
| 51         | HIB        | O        | OD                       | An output that indicates the processor is in Hibernate mode.                                                                                                                                                                                   |
| 52         | XOSC0      | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register. |
|            | XOSC1      | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                        |
| 54         | GND        | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| 55         | VBAT       | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                               |
| 56         | VDD        | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |
| 57         | GND        | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| 58         | MDIO       | I/O      | OD                       | MDIO of the Ethernet PHY.                                                                                                                                                                                                                      |
| 59         | PF3        | I/O      | TTL                      | GPIO port F bit 3.                                                                                                                                                                                                                             |
|            | LED0       | O        | TTL                      | Ethernet LED 0.                                                                                                                                                                                                                                |
|            | SSI1Fss    | I/O      | TTL                      | SSI module 1 frame signal.                                                                                                                                                                                                                     |
| 60         | PF2        | I/O      | TTL                      | GPIO port F bit 2.                                                                                                                                                                                                                             |

Table 23-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                   |
|------------|----------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 65         | PB3      | I/O      | TTL                      | GPIO port B bit 3.                                                                                                                                                                                                                                            |
|            | I2C0SDA  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                                               |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
| 66         | PB0      | I/O      | TTL                      | GPIO port B bit 0. This pin is not 5-V tolerant.                                                                                                                                                                                                              |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                                                                                                                        |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                    |
|            | USB0ID   | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| 67         | PB1      | I/O      | TTL                      | GPIO port B bit 1. This pin is not 5-V tolerant.                                                                                                                                                                                                              |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                                                                                                        |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                        |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                   |
|            | USB0VBUS | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |
| 68         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                       |
| 69         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                      |
| 70         | USB0DM   | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
| 71         | USB0DP   | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |

|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                                                                                                                                                                                                                                                     |
|            | I2S0TXSCK | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit clock.                                                                                                                                                                                                                                                                                  |
| 91         | VREFA     | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231. |
|            | PB5       | I/O      | TTL                      | GPIO port B bit 5.                                                                                                                                                                                                                                                                                                         |

|            | I2S0TXSCK  | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit clock.                                   |
|            | U2Tx       | O        | TTL                      | UART module 2 transmit. When in IrDA mode, this signal has IrDA modulation. |
| 100        | PD7        | I/O      | TTL                      | GPIO port D bit 7.                                                          |
|            | AIN4       | I        | Analog                   | Analog-to-digital converter input 4.                                        |
|            | C0o        | O        | TTL                      | Analog comparator 0 output.                                                 |
|            | CCP1       | I/O      | TTL                      | Capture/Compare/PWM 1.                                                      |
|            | EPI0S30    | I/O      | TTL                      | EPI module 0 signal 30.                                                     |
|            | I2S0TXWS   | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit word select.                             |
|            | U1DTR      | O        | TTL                      | UART module 1 Data Terminal Ready modem status input signal.                |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 23.1.2 Signals by Signal Name

Table 23-3. Signals by Signal Name

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                          |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------|
| AIN0     | 1          | PE7                      | I        | Analog                   | Analog-to-digital converter input 0. |
| AIN1     | 2          | PE6                      | I        | Analog                   | Analog-to-digital converter input 1. |

Table 23-3. Signals by Signal Name (continued)

| Pin Name | Pin Number                  | Pin Mux / Pin Assignment                            | Pin Type | Buffer Type <sup>a</sup> | Description                           |
|----------|-----------------------------|-----------------------------------------------------|----------|--------------------------|---------------------------------------|
| AIN2     | 5                           | PE5                                                 | I        | Analog                   | Analog-to-digital converter input 2.  |
| AIN3     | 6                           | PE4                                                 | I        | Analog                   | Analog-to-digital converter input 3.  |
| AIN4     | 100                         | PD7                                                 | I        | Analog                   | Analog-to-digital converter input 4.  |
| AIN5     | 99                          | PD6                                                 | I        | Analog                   | Analog-to-digital converter input 5.  |
| AIN6     | 98                          | PD5                                                 | I        | Analog                   | Analog-to-digital converter input 6.  |
| AIN7     | 97                          | PD4                                                 | I        | Analog                   | Analog-to-digital converter input 7.  |
| AIN8     | 96                          | PE3                                                 | I        | Analog                   | Analog-to-digital converter input 8.  |
| AIN9     | 95                          | PE2                                                 | I        | Analog                   | Analog-to-digital converter input 9.  |
| AIN10    | 92                          | PB4                                                 | I        | Analog                   | Analog-to-digital converter input 10. |
| AIN11    | 91                          | PB5                                                 | I        | Analog                   | Analog-to-digital converter input 11. |
| AIN12    | 13                          | PD3                                                 | I        | Analog                   | Analog-to-digital converter input 12. |

Table 23-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                      |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------------------|
| PA4      | 30         | -                        | I/O      | TTL                      | GPIO port A bit 4.                               |
| PA5      | 31         | -                        | I/O      | TTL                      | GPIO port A bit 5.                               |
| PA6      | 34         | -                        | I/O      | TTL                      | GPIO port A bit 6.                               |
| PA7      | 35         | -                        | I/O      | TTL                      | GPIO port A bit 7.                               |
| PB0      | 66         | -                        | I/O      | TTL                      | GPIO port B bit 0. This pin is not 5-V tolerant. |
| PB1      | 67         | -                        | I/O      | TTL                      | GPIO port B bit 1. This pin is not 5-V tolerant. |
| PB2      | 72         | -                        | I/O      | TTL                      | GPIO port B bit 2.                               |
| PB3      | 65         | -                        | I/O      | TTL                      | GPIO port B bit 3.                               |
| PB4      | 92         | -                        | I/O      | TTL                      | GPIO port B bit 4.                               |
| PB5      | 91         | -                        | I/O      | TTL                      | GPIO port B bit 5.                               |
| PB6      | 90         | -                        | I/O      | TTL                      | GPIO port B bit 6.                               |
| PB7      | 89         | -                        | I/O      | TTL                      | GPIO port B bit 7.                               |
| PC0      | 80         | -                        | I/O      | TTL                      | GPIO port C bit 0.                               |
| PC1      | 79         | -                        | I/O      | TTL                      | GPIO port C bit 1.                               |
| PC2      | 78         | -                        | I/O      | TTL                      | GPIO port C bit 2.                               |
| PC3      | 77         | -                        | I/O      | TTL                      | GPIO port C bit 3.                               |
| PC4      | 25         | -                        | I/O      | TTL                      | GPIO port C bit 4.                               |
| PC5      | 24         | -                        | I/O      | TTL                      | GPIO port C bit 5.                               |
| PC6      | 23         | -                        | I/O      | TTL                      | GPIO port C bit 6.                               |
| PC7      | 22         | -                        | I/O      | TTL                      | GPIO port C bit 7.                               |
| PD0      | 10         | -                        | I/O      | TTL                      | GPIO port D bit 0.                               |
| PD1      | 11         | -                        | I/O      | TTL                      | GPIO port D bit 1.                               |
| PD2      | 12         | -                        | I/O      | TTL                      | GPIO port D bit 2.                               |
| PD3      | 13         | -                        | I/O      | TTL                      | GPIO port D bit 3.                               |
| PD4      | 97         | -                        | I/O      | TTL                      | GPIO port D bit 4.                               |
| PD5      | 98         | -                        | I/O      | TTL                      | GPIO port D bit 5.                               |
| PD6      | 99         | -                        | I/O      | TTL                      | GPIO port D bit 6.                               |
| PD7      | 100        | -                        | I/O      | TTL                      | GPIO port D bit 7.                               |
| PE0      | 74         | -                        | I/O      | TTL                      | GPIO port E bit 0.                               |
| PE1      | 75         | -                        | I/O      | TTL                      | GPIO port E bit 1.                               |
| PE2      | 95         | -                        | I/O      | TTL                      | GPIO port E bit 2.                               |
| PE3      | 96         | -                        | I/O      | TTL                      | GPIO port E bit 3.                               |
| PE4      | 6          | -                        | I/O      | TTL                      | GPIO port E bit 4.                               |
| PE5      | 5          | -                        | I/O      | TTL                      | GPIO port E bit 5.                               |
| PE6      | 2          | -                        | I/O      | TTL                      | GPIO port E bit 6.                               |
| PE7      | 1          | -                        | I/O      | TTL                      | GPIO port E bit 7.                               |
| PF0      | 47         | -                        | I/O      | TTL                      | GPIO port F bit 0.                               |
| PF1      | 61         | -                        | I/O      | TTL                      | GPIO port F bit 1.                               |
| PF2      | 60         | -                        | I/O      | TTL                      | GPIO port F bit 2.                               |
| PF3      | 59         | -                        | I/O      | TTL                      | GPIO port F bit 3.                               |
| PF4      | 42         | -                        | I/O      | TTL                      | GPIO port F bit 4.                               |

Table 23-3. Signals by Signal Name (continued)

| Pin Name | Pin Number     | Pin Mux / Pin Assignment       | Pin Type | Buffer Type <sup>a</sup> | Description                |
|----------|----------------|--------------------------------|----------|--------------------------|----------------------------|
| PF5      | 41             | -                              | I/O      | TTL                      | GPIO port F bit 5.         |
| PG0      | 19             | -                              | I/O      | TTL                      | GPIO port G bit 0.         |
| PG1      | 18             | -                              | I/O      | TTL                      | GPIO port G bit 1.         |
| PG7      | 36             | -                              | I/O      | TTL                      | GPIO port G bit 7.         |
| PH0      | 86             | -                              | I/O      | TTL                      | GPIO port H bit 0.         |
| PH1      | 85             | -                              | I/O      | TTL                      | GPIO port H bit 1.         |
| PH2      | 84             | -                              | I/O      | TTL                      | GPIO port H bit 2.         |

| USB0DM   | 70                               | fixed                                                          | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
| USB0DP   | 71                               | fixed                                                          | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
| USB0EPEN | 19<br>24<br>34<br>72<br>83       | PG0 (7)<br>PC5 (6)<br>PA6 (8)<br>PB2 (8)<br>PH3 (4)            | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
| USB0ID   | 66                               | PB0                                                            | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |

Table 23-3. Signals by Signal Name (continued)

| Pin Name  | Pin Number                                  | Pin Mux / Pin Assignment                                                  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------|---------------------------------------------------------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB0PFLT  | 22<br>23<br>35<br>65<br>74<br>76<br>87      | PC7 (6)<br>PC6 (7)<br>PA7 (8)<br>PB3 (8)<br>PE0 (9)<br>PH4 (4)<br>PJ1 (9) | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                                                                                                 |
| USB0RBIAS | 73                                          | fixed                                                                     | O        | Analog                   | 9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.                                                                                                                                                                                                                                                                  |
| USB0VBUS  | 67                                          | PB1                                                                       | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                                                                                                        |
| VBAT      | 55                                          | fixed                                                                     | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                                                                                                          |
| VDD       | 8<br>20<br>32<br>44<br>56<br>68<br>81<br>93 | fixed                                                                     | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                   |
| VDDA      | 3                                           | fixed                                                                     | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 25-2 on page 1213 , regardless of system implementation. |
| VDDC      | 38<br>88                                    | fixed                                                                     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.3 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to the LDO pin and an external capacitor as specified in .                                                                 |
| VREFA     | 90                                          | PB6                                                                       | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231 .               |
| WAKE      | 50                                          | fixed                                                                     | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                                                                                                          |
| XOSC0     | 52                                          | fixed                                                                     | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register.                                                                                            |

Table 23-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                 |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XOSC1    | 53         | fixed                    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                     |
| XTALNPHY | 17         | fixed                    | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output. Leave this pin unconnected when using a single-ended 25-MHz clock input connected to the XTALPPHY pin. |
| XTALPPHY | 16         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input or external clock reference input.                                                                       |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 23.1.3 Signals by Function, Except for GPIO

Table 23-4. Signals by Function, Except for GPIO

| Function | Pin Name | Pin Number | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                 |
|----------|----------|------------|----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADC      | AIN0     | 1          | I        | Analog                   | Analog-to-digital converter input 0.                                                                                                                                                                                                                                                                                        |
|          | AIN1     | 2          | I        | Analog                   | Analog-to-digital converter input 1.                                                                                                                                                                                                                                                                                        |
|          | AIN2     | 5          | I        | Analog                   | Analog-to-digital converter input 2.                                                                                                                                                                                                                                                                                        |
|          | AIN3     | 6          | I        | Analog                   | Analog-to-digital converter input 3.                                                                                                                                                                                                                                                                                        |
|          | AIN4     | 100        | I        | Analog                   | Analog-to-digital converter input 4.                                                                                                                                                                                                                                                                                        |

|          | VREFA    | 90         | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231 . |

Table 23-4. Signals by Function, Except for GPIO (continued)

| Function                | Pin Name | Pin Number                  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                 |

Table 23-4. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number                                  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |
|----------|----------|---------------------------------------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power    | GND      | 9<br>21<br>45<br>54<br>57<br>69<br>82<br>94 | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                 |
|          | GNDA     | 4                                           | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
|          | LDO      | 7                                           | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. The LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).                                                                                       |
|          | VDD      | 8<br>20<br>32<br>44<br>56<br>68<br>81<br>93 | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
|          | VDDA     | 3                                           | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 25-2 on page 1213, regardless of system implementation. |
|          | VDDC     | 38<br>88                                    | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.3 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to the LDO pin and an external capacitor as specified in .                                                                |
| SSI      | SSI0Clk  | 28                                          | I/O      | TTL                      | SSI module 0 clock                                                                                                                                                                                                                                                                                                                       |

|          | USB0DP    | 71                                     | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0EPEN  | 19<br>24<br>34<br>72<br>83             | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
|          | USB0ID    | 66                                     | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
|          | USB0PFLT  | 22<br>23<br>35<br>65<br>74<br>76<br>87 | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
|          | USB0RBIAS | 73                                     | O        | Analog                   | 9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.                                                                                                                                                                                      |
|          | USB0VBUS  | 67                                     | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

|            | CCP1      | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                                                                                                                                                                     |
|            | CCP5      | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                                                                                                                                                                                                                                                     |
|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                                                                                                                                                                                                                                                     |
|            | I2S0TXSCK | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit clock.                                                                                                                                                                                                                                                                                  |
|            | VREFA     | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231. |
| A8         | PB7       | I/O      | TTL                      | GPIO port B bit 7.                                                                                                                                                                                                                                                                                                         |
|            | NMI       | I        | TTL                      | Non-maskable interrupt.                                                                                                                                                                                                                                                                                                    |

|            | EPI0S6     | I/O      | TTL                      | EPI module 0 signal 6.                                                                                                                                                                                                                                                                                                                    |
| C10        | PG7        | I/O      | TTL                      | GPIO port G bit 7.                                                                                                                                                                                                                                                                                                                        |
|            | CCP5       | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                                                                                                                                                                                                                                                                    |
|            | EPI0S31    | I/O      | TTL                      | EPI module 0 signal 31.                                                                                                                                                                                                                                                                                                                   |

Table 23-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                               |
|------------|----------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C11        | USB0DM   | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                                  |
| C12        | USB0DP   | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                                  |
| D1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |
| D2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |
| D3         | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.3 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to the LD0 pin and an external capacitor as specified in . |
| D10        | PH3      | I/O      | TTL                      | GPIO port H bit 3.                                                                                                                                                                                                                                                        |
|            | EPI0S0   | I/O      | TTL                      | EPI module 0 signal 0.                                                                                                                                                                                                                                                    |
|            | USB0EPEN | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                                          |
| D11        | PH2      | I/O      | TTL                      | GPIO port H bit 2.                                                                                                                                                                                                                                                        |
|            | C10      | O        | TTL                      | Analog comparator 1 output.                                                                                                                                                                                                                                               |
|            | EPI0S1   | I/O      | TTL                      | EPI module 0 signal 1.                                                                                                                                                                                                                                                    |
| D12        | PB1      | I/O      | TTL                      | GPIO port B bit 1. This pin is not 5-V tolerant.                                                                                                                                                                                                                          |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                                                                                                                    |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                                    |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                               |
|            | USB0VBUS | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                                        |
| E1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |
| E2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |
| E3         | LD0      | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. The LD0 pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).                        |
| E10        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                   |
| E11        | PB3      | I/O      | TTL                      | GPIO port B bit 3.                                                                                                                                                                                                                                                        |
|            | I2C0SDA  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                                                           |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                                 |
| E12        | PB0      | I/O      | TTL                      | GPIO port B bit 0. This pin is not 5-V tolerant.                                                                                                                                                                                                                          |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                                                                                                                                    |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                |
|            | USB0ID   | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).             |
| F1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |
| F2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                              |

Table 23-7. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                 |
|------------|-----------|----------|--------------------------|-----------------------------------------------------------------------------|
| F3         | PJ0       | I/O      | TTL                      | GPIO port J bit 0.                                                          |
|            | EPI0S16   | I/O      | TTL                      | EPI module 0 signal 16.                                                     |
|            | I2C1SCL   | I/O      | OD                       | I <sup>2</sup> C module 1 clock.                                            |
| F10        | PH5       | I/O      | TTL                      | GPIO port H bit 5.                                                          |
|            | EPI0S11   | I/O      | TTL                      | EPI module 0 signal 11.                                                     |
|            | SSI1Fss   | I/O      | TTL                      | SSI module 1 frame signal.                                                  |
| F11        | GND       | -        | Power                    | Ground reference for logic and I/O pins.                                    |
| F12        | GND       | -        | Power                    | Ground reference for logic and I/O pins.                                    |
| G1         | PD0       | I/O      | TTL                      | GPIO port D bit 0.                                                          |
|            | AIN15     | I        | Analog                   | Analog-to-digital converter input 15.                                       |
|            | CAN0Rx    | I        | TTL                      | CAN module 0 receive.                                                       |
|            | CCP6      | I/O      | TTL                      | Capture/Compare/PWM 6.                                                      |
|            | I2S0RXSCK | I/O      | TTL                      | I <sup>2</sup> S module 0 receive clock.                                    |
|            | U1CTS     | I        | TTL                      | UART module 1 Clear To Send modem flow control input signal.                |
|            | U1Rx      | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.  |
|            | U2Rx      | I        | TTL                      | UART module 2 receive. When in IrDA mode, this signal has IrDA modulation.  |
| G2         | PD1       | I/O      | TTL                      | GPIO port D bit 1.                                                          |
|            | AIN14     | I        | Analog                   | Analog-to-digital converter input 14.                                       |
|            | CAN0Tx    | O        | TTL                      | CAN module 0 transmit.                                                      |
|            | CCP2      | I/O      | TTL                      | Capture/Compare/PWM 2.                                                      |
|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                      |
|            | I2S0RXWS  | I/O      | TTL                      | I <sup>2</sup> S module 0 receive word select.                              |
|            | U1DCD     | I        | TTL                      | UART module 1 Data Carrier Detect modem status input signal.                |
|            | U1Tx      | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |
|            | U2Tx      | O        | TTL                      | UART module 2 transmit. When in IrDA mode, this signal has IrDA modulation. |
| G3         | PH6       | I/O      | TTL                      | GPIO port H bit 6.                                                          |
|            | EPI0S26   | I/O      | TTL                      | EPI module 0 signal 26.                                                     |
|            | SSI1Rx    | I        | TTL                      | SSI module 1 receive.                                                       |
| G10        | VDD       | -        | Power                    | Positive supply for I/O and some logic.                                     |
| G11        | VDD       | -        | Power                    | Positive supply for I/O and some logic.                                     |
| G12        | VDD       | -        | Power                    | Positive supply for I/O and some logic.                                     |
| H1         | PD3       | I/O      | TTL                      | GPIO port D bit 3.                                                          |
|            | AIN12     | I        | Analog                   | Analog-to-digital converter input 12.                                       |
|            | CCP0      | I/O      | TTL                      | Capture/Compare/PWM 0.                                                      |
|            | CCP7      | I/O      | TTL                      | Capture/Compare/PWM 7.                                                      |
|            | EPI0S21   | I/O      | TTL                      | EPI module 0 signal 21.                                                     |
|            | U1Tx      | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |

Table 23-7. Signals by Pin Number (continued)

| Pin Number | Pin Name   | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                 |
|------------|------------|----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H2         | PD2        | I/O      | TTL                      | GPIO port D bit 2.                                                                                                                                          |
|            | AIN13      | I        | Analog                   | Analog-to-digital converter input 13.                                                                                                                       |
|            | CCP5       | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                                                                                      |
|            | CCP6       | I/O      | TTL                      | Capture/Compare/PWM 6.                                                                                                                                      |
|            | EPI0S20    | I/O      | TTL                      | EPI module 0 signal 20.                                                                                                                                     |
|            | U1Rx       | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                  |
| H3         | PH7        | I/O      | TTL                      | GPIO port H bit 7.                                                                                                                                          |
|            | EPI0S27    | I/O      | TTL                      | EPI module 0 signal 27.                                                                                                                                     |
|            | SSI1Tx     | O        | TTL                      | SSI module 1 transmit.                                                                                                                                      |
| H10        | VDD        | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                     |
| H11        | RST        | I        | TTL                      | System reset input.                                                                                                                                         |

| L10        | GND       | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                         |
| L11        | OSC0      | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                                                                                                              |
| L12        | VBAT      | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| M1         | PC5       | I/O      | TTL                      | GPIO port C bit 5.                                                                                                                                                               |
|            | C0o       | O        | TTL                      | Analog comparator 0 output.                                                                                                                                                      |
|            | C1+       | I        | Analog                   | Analog comparator 1 positive input.                                                                                                                                              |
|            | C1o       | O        | TTL                      | Analog comparator 1 output.                                                                                                                                                      |
|            | CCP1      | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                           |
|            | CCP3      | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                                                                                           |
|            | EPI0S3    | I/O      | TTL                      | EPI module 0 signal 3.                                                                                                                                                           |
|            | USB0EPEN  | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                 |

Table 23-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                               |
|------------|----------|----------|--------------------------|-----------------------------------------------------------------------------------------------------------|
| M2         | PC6      | I/O      | TTL                      | GPIO port C bit 6.                                                                                        |
|            | C2+      | I        | Analog                   | Analog comparator 2 positive input.                                                                       |
|            | C2o      | O        | TTL                      | Analog comparator 2 output.                                                                               |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                    |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                    |
|            | EPI0S4   | I/O      | TTL                      | EPI module 0 signal 4.                                                                                    |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| M3         | PA1      | I/O      | TTL                      | GPIO port A bit 1.                                                                                        |
|            | I2C1SDA  | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                           |
|            | U0Tx     | O        | TTL                      | UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.                               |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                               |
| M4         | PA2      | I/O      | TTL                      | GPIO port A bit 2.                                                                                        |
|            | I2S0RXSD | I/O      | TTL                      | I <sup>2</sup> S module 0 receive data.                                                                   |
|            | SSI0Clk  | I/O      | TTL                      | SSI module 0 clock                                                                                        |
| M5         | PA5      | I/O      | TTL                      | GPIO port A bit 5.                                                                                        |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                                    |
|            | I2S0TXWS | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit word select.                                                           |
|            | SSI0Tx   | O        | TTL                      | SSI module 0 transmit                                                                                     |
| M6         | PA7      | I/O      | TTL                      | GPIO port A bit 7.                                                                                        |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                                    |

|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                                    |
|            | I2C1SDA  | I/O      | OD                       | I <sup>2</sup> C module 1 data.                                                                           |
|            | U1DCD    | I        | TTL                      | UART module 1 Data Carrier Detect modem status input signal.                                              |
|            | USB0PFLT | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source. |
| M7         | RXIP     | I        | Analog                   | RXIP of the Ethernet PHY.                                                                                 |
| M8         | TXOP     | O        | TTL                      | TXOP of the Ethernet PHY.                                                                                 |
| M9         | PF0      | I/O      | TTL                      | GPIO port F bit 0.                                                                                        |
|            | CAN1Rx   | I        | TTL                      | CAN module 1 receive.                                                                                     |
|            | I2S0TXSD | I/O      | TTL                      | I <sup>2</sup> S module 0 transmit data.                                                                  |
|            | U1DSR    | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                                                   |
| M10        | WAKE     | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                          |
| M11        | OSC1     | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.                 |
| M12        | HIB      | O        | OD                       | An output that indicates the processor is in Hibernate mode.                                              |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 23.2.2 Signals by Signal Name

Table 23-8. Signals by Signal Name

| Pin Name | Pin Number                  | Pin Mux / Pin Assignment                            | Pin Type | Buffer Type <sup>a</sup> | Description                           |
|----------|-----------------------------|-----------------------------------------------------|----------|--------------------------|---------------------------------------|
| AIN0     | B1                          | PE7                                                 | I        | Analog                   | Analog-to-digital converter input 0.  |
| AIN1     | A1                          | PE6                                                 | I        | Analog                   | Analog-to-digital converter input 1.  |
| AIN2     | B3                          | PE5                                                 | I        | Analog                   | Analog-to-digital converter input 2.  |
| AIN3     | B2                          | PE4                                                 | I        | Analog                   | Analog-to-digital converter input 3.  |
| AIN4     | A2                          | PD7                                                 | I        | Analog                   | Analog-to-digital converter input 4.  |
| AIN5     | A3                          | PD6                                                 | I        | Analog                   | Analog-to-digital converter input 5.  |
| AIN6     | C6                          | PD5                                                 | I        | Analog                   | Analog-to-digital converter input 6.  |
| AIN7     | B5                          | PD4                                                 | I        | Analog                   | Analog-to-digital converter input 7.  |
| AIN8     | B4                          | PE3                                                 | I        | Analog                   | Analog-to-digital converter input 8.  |
| AIN9     | A4                          | PE2                                                 | I        | Analog                   | Analog-to-digital converter input 9.  |
| AIN10    | A6                          | PB4                                                 | I        | Analog                   | Analog-to-digital converter input 10. |
| AIN11    | B7                          | PB5                                                 | I        | Analog                   | Analog-to-digital converter input 11. |
| AIN12    | H1                          | PD3                                                 | I        | Analog                   | Analog-to-digital converter input 12. |
| AIN13    | H2                          | PD2                                                 | I        | Analog                   | Analog-to-digital converter input 13. |
| AIN14    | G2                          | PD1                                                 | I        | Analog                   | Analog-to-digital converter input 14. |
| AIN15    | G1                          | PD0                                                 | I        | Analog                   | Analog-to-digital converter input 15. |

| USB0EPEN  | K1<br>M1<br>L6<br>A11<br>D10                      | PG0 (7)<br>PC5 (6)<br>PA6 (8)<br>PB2 (8)<br>PH3 (4)                       | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                                                                                                         |
| USB0ID    | E12                                               | PB0                                                                       | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).                                                                            |
| USB0PFLT  | L2<br>M2<br>M6<br>E11<br>B11<br>B10<br>B6         | PC7 (6)<br>PC6 (7)<br>PA7 (8)<br>PB3 (8)<br>PE0 (9)<br>PH4 (4)<br>PJ1 (9) | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                                                                                                |
| USB0RBIAS | B12                                               | fixed                                                                     | O        | Analog                   | 9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.                                                                                                                                                                                                                                                                 |
| USB0VBUS  | D12                                               | PB1                                                                       | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                                                                                                       |
| VBAT      | L12                                               | fixed                                                                     | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                                                                                                                         |
| VDD       | K7<br>G12<br>K8<br>K9<br>H10<br>G10<br>E10<br>G11 | fixed                                                                     | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
| VDDA      | C7                                                | fixed                                                                     | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 25-2 on page 1213, regardless of system implementation. |
| VDDC      | D3<br>C3                                          | fixed                                                                     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.3 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to the LDO pin and an external capacitor as specified in .                                                                |

Table 23-8. Signals by Signal Name (*continued*)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                |
|----------|------------|--------------------------|----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VREFA    | A7         | PB6                      | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231. |
| WAKE     | M10        | fixed                    | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                                                                                           |
| XOSC0    | K11        | fixed                    | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register.                                                                             |
| XOSC1    | K12        | fixed                    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                                                                                                    |
| XTALNPHY | J1         | fixed                    | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output. Leave this pin unconnected when using a single-ended 25-MHz clock input connected to the XTALPPHY pin.                                                                                                                                                                |
| XTALPPHY | J2         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input or external clock reference input.                                                                                                                                                                                                                                      |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 23.2.3 Signals by Function, Except for GPIO

Table 23-9. Signals by Function, Except for GPIO

| Function           | Pin Name | Pin Number                  | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                 |

|                    | VREFA    | A7                          | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 1023. The VREFA input is limited to the range specified in Table 25-27 on page 1231 . |

Table 23-9. Signals by Function, Except for GPIO (continued)

| Function     | Pin Name   | Pin Number           | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                             |
|--------------|------------|----------------------|----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hibernate    | HIB        | M12                  | O        | OD                       | An output that indicates the processor is in Hibernate mode.                                                                                                                                                                            |
|              | VBAT       | L12                  | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                        |
|              | WAKE       | M10                  | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                        |
|              | XOSC0      | K11                  | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the HIBCTL register. |
|              | XOSC1      | K12                  | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                 |
| I2C          | I2C0SCL    | A11                  | I/O      | OD                       | I <sup>2</sup> C module 0 clock.                                                                                                                                                                                                        |
|              | I2C0SDA    | E11                  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                         |

Table 23-9. Signals by Function, Except for GPIO (*continued*)

| Function | Pin Name | Pin Number                                        | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                              |
|----------|----------|---------------------------------------------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power    | GND      | C4<br>C5<br>K5<br>L10<br>K10<br>J10<br>F11<br>F12 | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                                                 |
|          | GNDA     | A5                                                | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                                                        |
|          | LD0      | E3                                                | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. The LD0 pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).                                                                                       |
|          | VDD      | K7<br>G12<br>K8<br>K9<br>H10<br>G10<br>E10<br>G11 | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                                  |
|          | VDDA     | C7                                                | -        | Power                    | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in Table 25-2 on page 1213, regardless of system implementation. |
|          | VDDC     | D3<br>C3                                          | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.3 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to the LD0 pin and an external capacitor as specified in .                                                                |

| Function | Pin Name  | Pin Number                                | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                   |
|----------|-----------|-------------------------------------------|----------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB      | USB0DM    | C11                                       | I/O      | Analog                   | Bidirectional differential data pin (D- per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0DP    | C12                                       | I/O      | Analog                   | Bidirectional differential data pin (D+ per USB specification) for USB0.                                                                                                                                                                                      |
|          | USB0EPEN  | K1<br>M1<br>L6<br>A11<br>D10              | O        | TTL                      | Optionally used in Host mode to control an external power source to supply power to the USB bus.                                                                                                                                                              |
|          | USB0ID    | E12                                       | I        | Analog                   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
|          | USB0PFLT  | L2<br>M2<br>M6<br>E11<br>B11<br>B10<br>B6 | I        | TTL                      | Optionally used in Host mode by an external power source to indicate an error state by that power source.                                                                                                                                                     |
|          | USB0RBIAS | B12                                       | O        | Analog                   | 9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.                                                                                                                                                                                      |
|          | USB0VBUS  | D12                                       | I/O      | Analog                   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.                                                                            |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 23.3 Connections for Unused Signals

Table 23-12 on page 1210 shows how to handle signals for functions that are not used in a particular system implementation for devices that are in a 100-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it

is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

**Table 23-12. Connections for Unused Signals (100-Pin LQFP)**

| Function       | Signal Name           | Pin Number | Acceptable Practice                        | Preferred Practice                                             |
|----------------|-----------------------|------------|--------------------------------------------|----------------------------------------------------------------|
| Ethernet       | ERBIAS                | 33         | Connect to GND through 12.4-kΩ resistor.   | Connect to GND through 12.4-kΩ resistor.                       |
|                | RXIN                  | 37         | NC                                         | GND                                                            |

|                | OSC1                  | 49         | NC                                         | NC                                                             |
|                | RST                   | 64         | Pull up as shown in Figure 5-1 on page 200 | Connect through a capacitor to GND as close to pin as possible |
| USB            | USB0DM                | 70         | NC                                         | GND                                                            |
|                | USB0DP                | 71         | NC                                         | GND                                                            |
|                | USB0RBIAS             | 73         | Connect to GND through 10-kΩ resistor.     | Connect to GND through 10-kΩ resistor.                         |

a. Note that the Ethernet PHY is powered up by default. The PHY cannot be powered down unless a clock source is provided and the MDIO pin is pulled up through a 10-kΩ resistor.

Table 23-13 on page 1211 shows how to handle signals for functions that are not used in a particular system implementation for devices that are in a 108-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

**Table 23-13. Connections for Unused Signals (108-Ball BGA)**

| Function       | Signal Name           | Pin Number | Acceptable Practice                        | Preferred Practice                                             |
|----------------|-----------------------|------------|--------------------------------------------|----------------------------------------------------------------|
| Ethernet       | ERBIAS                | J3         | Connect to GND through 12.4-kΩ resistor.   | Connect to GND through 12.4-kΩ resistor.                       |

| No Connects    | NC                    | -          | NC                                         | NC                                                             |
| System Control | OSC0                  | L11        | NC                                         | GND                                                            |
|                | OSC1                  | M11        | NC                                         | NC                                                             |
|                | RST                   | H11        | Pull up as shown in Figure 5-1 on page 200 | Connect through a capacitor to GND as close to pin as possible |
| USB            | USB0BIAS              | B12        | Connect to GND through 10-kΩ resistor.     | Connect to GND through 10-kΩ resistor.                         |
|                | USB0DM                | C11        | NC                                         | GND                                                            |
|                | USB0DP                | C12        | NC                                         | GND                                                            |

a. Note that the Ethernet PHY is powered up by default. The PHY cannot be powered down unless a clock source is provided and the MDIO pin is pulled up through a 10-kΩ resistor.

## 24 Operating Characteristics

**Table 24-1. Temperature Characteristics**

| Characteristic                         | Symbol | Value       | Unit |
|----------------------------------------|--------|-------------|------|
| Industrial operating temperature range | $T_A$  | -40 to +85  | °C   |
| Unpowered storage temperature range    | $T_S$  | -65 to +150 | °C   |

**Table 24-2. Thermal Characteristics**

| Characteristic                                        | Symbol        | Value                         | Unit |
|-------------------------------------------------------|---------------|-------------------------------|------|
| Thermal resistance (junction to ambient) <sup>a</sup> | $\Theta_{JA}$ | 35 (100LQFP)<br>33 (108BGA)   | °C/W |
| Junction temperature, -40 to +125 <sup>b</sup>        | $T_J$         | $T_A + (P \cdot \Theta_{JA})$ | °C   |

a. Junction to ambient thermal resistance  $\Theta_{JA}$  numbers are determined by a package simulator.

b. Power dissipation is a function of temperature.

**Table 24-3. ESD Absolute Maximum Ratings<sup>a</sup>**

| Parameter Name | Min | Nom | Max | Unit |
|----------------|-----|-----|-----|------|
| $V_{ESDHBM}$   | -   | -   | 2.0 | kV   |
| $V_{ESDCDM}$   | -   | -   | 500 | V    |

a. All Stellaris<sup>®</sup> parts are ESD tested following the JEDEC standard.

## 25 Electrical Characteristics

### 25.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 25-1. Maximum Ratings**

| Parameter             | Parameter Name <sup>a</sup>                                                    | Value |                       | Unit |
|-----------------------|--------------------------------------------------------------------------------|-------|-----------------------|------|
|                       |                                                                                | Min   | Max                   |      |
| V <sub>DD</sub>       | V <sub>DD</sub> supply voltage                                                 | 0     | 4                     | V    |
| V <sub>DDA</sub>      | V <sub>DDA</sub> supply voltage                                                | 0     | 4                     | V    |
| V <sub>BAT</sub>      | V <sub>BAT</sub> battery supply voltage                                        | 0     | 4                     | V    |
| V <sub>IN_GPIO</sub>  | Input voltage <sup>b</sup>                                                     | -0.3  | 5.5                   | V    |
|                       | Input voltage for PB0 and PB1 when configured as GPIO                          | -0.3  | V <sub>DD</sub> + 0.3 | V    |
| I <sub>GPIO MAX</sub> | Maximum current per output pin                                                 | -     | 25                    | mA   |
| V <sub>NON</sub>      | Maximum input voltage on a non-power pin when the microcontroller is unpowered | -     | 300                   | mV   |

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

**Important:** This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1209).

### 25.2 Recommended Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V<sub>OL</sub> value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package or BGA pin group with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 25-2. Recommended DC Operating Conditions**

| Parameter        | Parameter Name                            | Min   | Nom | Max   | Unit |
|------------------|-------------------------------------------|-------|-----|-------|------|
| V <sub>DD</sub>  | V <sub>DD</sub> supply voltage            | 3.0   | 3.3 | 3.6   | V    |
| V <sub>DDA</sub> | V <sub>DDA</sub> supply voltage           | 3.0   | 3.3 | 3.6   | V    |
| V <sub>DDC</sub> | V <sub>DDC</sub> supply voltage, run mode | 1.235 | 1.3 | 1.365 | V    |
| V <sub>IH</sub>  | High-level input voltage                  | 2.1   | -   | 5.0   | V    |
| V <sub>IL</sub>  | Low-level input voltage                   | -0.3  | -   | 1.2   | V    |

Table 25-2. Recommended DC Operating Conditions (continued)

| Parameter | Parameter Name                                     | Min  | Nom | Max | Unit |
|-----------|----------------------------------------------------|------|-----|-----|------|
| $V_{OH}$  | High-level output voltage                          | 2.4  | -   | -   | V    |
| $V_{OL}$  | Low-level output voltage                           | -    | -   | 0.4 | V    |
| $I_{OH}$  | High-level source current, $V_{OH}=2.4\text{ V}^a$ |      |     |     |      |
|           | 2-mA Drive                                         | -2.0 | -   | -   | mA   |
|           | 4-mA Drive                                         | -4.0 | -   | -   | mA   |
|           | 8-mA Drive                                         | -8.0 | -   | -   | mA   |
| $I_{OL}$  | Low-level sink current, $V_{OL}=0.4\text{ V}^a$    |      |     |     |      |
|           | 2-mA Drive                                         | 2.0  | -   | -   | mA   |
|           | 4-mA Drive                                         | 4.0  | -   | -   | mA   |
|           | 8-mA Drive                                         | 8.0  | -   | -   | mA   |
|           | 8-mA Drive, $V_{OL}=1.2\text{ V}$                  | 18.0 | -   | -   | mA   |

a.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

## 25.3 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

Figure 25-1. Load Conditions

## 25.4 JTAG and Boundary Scan

Table 25-3. JTAG Characteristics

| Parameter No. | Parameter       | Parameter Name                               | Min | Nom         | Max | Unit |
|---------------|-----------------|----------------------------------------------|-----|-------------|-----|------|
| J1            | $F_{TCK}$       | TCK operational clock frequency <sup>a</sup> | 0   | -           | 10  | MHz  |
| J2            | $T_{TCK}$       | TCK operational clock period                 | 100 | -           | -   | ns   |
| J3            | $T_{TCK\_LOW}$  | TCK clock Low time                           | -   | $t_{TCK}/2$ | -   | ns   |
| J4            | $T_{TCK\_HIGH}$ | TCK clock High time                          | -   | $t_{TCK}/2$ | -   | ns   |
| J5            | $T_{TCK\_R}$    | TCK rise time                                | 0   | -           | 10  | ns   |
| J6            | $T_{TCK\_F}$    | TCK fall time                                | 0   | -           | 10  | ns   |
| J7            | $T_{TMS\_SU}$   | TMS setup time to TCK rise                   | 20  | -           | -   | ns   |
| J8            | $T_{TMS\_HLD}$  | TMS hold time from TCK rise                  | 20  | -           | -   | ns   |
| J9            | $T_{TDI\_SU}$   | TDI setup time to TCK rise                   | 25  | -           | -   | ns   |
| J10           | $T_{TDI\_HLD}$  | TDI hold time from TCK rise                  | 25  | -           | -   | ns   |

Table 25-3. JTAG Characteristics (continued)

| Parameter No. | Parameter      | Parameter Name                                                            | Min | Nom | Max | Unit |
|---------------|----------------|---------------------------------------------------------------------------|-----|-----|-----|------|
| J11           | $T_{TDO\_ZDV}$ | TCK fall to Data Valid from High-Z, 2-mA drive                            | -   | 23  | 35  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 4-mA drive                            |     | 15  | 26  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 8-mA drive                            |     | 14  | 25  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control     |     | 18  | 29  | ns   |
| J12           | $T_{TDO\_DV}$  | TCK fall to Data Valid from Data Valid, 2-mA drive                        | -   | 21  | 35  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 4-mA drive                        |     | 14  | 25  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 8-mA drive                        |     | 13  | 24  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control |     | 18  | 28  | ns   |
| J13           | $T_{TDO\_DVZ}$ | TCK fall to High-Z from Data Valid, 2-mA drive                            | -   | 9   | 11  | ns   |
|               |                | TCK fall to High-Z from Data Valid, 4-mA drive                            |     | 7   | 9   | ns   |
|               |                | TCK fall to High-Z from Data Valid, 8-mA drive                            |     | 6   | 8   | ns   |
|               |                | TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control     |     | 7   | 9   | ns   |

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

## 25.5 Power and Brown-Out

Table 25-4. Power Characteristics

| Parameter No. | Parameter     | Parameter Name                                    | Min  | Nom | Max  | Unit    |
|---------------|---------------|---------------------------------------------------|------|-----|------|---------|
| P1            | $V_{TH}$      | Power-On Reset threshold                          | -    | 2   | -    | V       |
| P2            | $V_{BTH}$     | Brown-Out Reset threshold                         | 2.85 | 2.9 | 2.95 | V       |
| P3            | $T_{POR}$     | Power-On Reset timeout                            | 6    | -   | 18   | ms      |
| P4            | $T_{BOR}$     | Brown-Out timeout                                 | -    | 500 | -    | $\mu$ s |
| P5            | $T_{IRPOR}$   | Internal reset timeout after POR                  | -    | -   | 2    | ms      |
| P6            | $T_{IRBOR}$   | Internal reset timeout after BOR                  | -    | -   | 2    | ms      |
| P7            | $T_{VDDRISE}$ | Supply voltage ( $V_{DD}$ ) rise time (0V-3.0V)   | -    | -   | 10   | ms      |
| P8            | $T_{VDD2\_3}$ | Supply voltage ( $V_{DD}$ ) rise time (2.0V-3.0V) | -    | -   | 6    | ms      |

Figure 25-4. Power-On Reset Timing

Figure 25-5. Brown-Out Reset Timing

## 25.6 Reset

Table 25-5. Reset Characteristics

| Parameter No. | Parameter   | Parameter Name                                               | Min | Nom | Max | Unit    |
|---------------|-------------|--------------------------------------------------------------|-----|-----|-----|---------|
| R1            | $T_{IRHWR}$ | Internal reset timeout after hardware reset (RST pin)        | -   | -   | 2   | ms      |
| R2            | $T_{IRSWR}$ | Internal reset timeout after software-initiated system reset | -   | -   | 2   | ms      |
| R3            | $T_{IRWDR}$ | Internal reset timeout after watchdog reset                  | -   | -   | 2   | ms      |
| R4            | $T_{IRMFR}$ | Internal reset timeout after MOSC failure reset              | -   | -   | 2   | ms      |
| R5            | $T_{MIN}$   | Minimum RST pulse width <sup>a</sup>                         | 2   | -   | -   | $\mu$ s |

a. This specification must be met in order to guarantee proper reset operation.

Figure 25-10. MOSC Failure Reset Timing

## 25.7 On-Chip Low Drop-Out (LDO) Regulator

Table 25-6. LDO Regulator Characteristics

| Parameter | Parameter Name                                                        | Min   | Nom | Max   | Unit          |
|-----------|-----------------------------------------------------------------------|-------|-----|-------|---------------|
| $C_{LDO}$ | External filter capacitor size for internal power supply <sup>a</sup> | 1.0   | -   | 3.0   | $\mu\text{F}$ |
| $V_{LDO}$ | LDO output voltage                                                    | 1.235 | 1.3 | 1.365 | V             |

a. The capacitor should be connected as close as possible to pin 86.

## 25.8 Clocks

The following sections provide specifications on the various clock sources and mode.

### 25.8.1 PLL Specifications

The following tables provide specifications for using the PLL.

Table 25-7. Phase Locked Loop (PLL) Characteristics

| Parameter       | Parameter Name                        | Min                | Nom | Max               | Unit |
|-----------------|---------------------------------------|--------------------|-----|-------------------|------|
| $F_{REF\_XTAL}$ | Crystal reference <sup>a</sup>        | 3.579545           | -   | 16.384            | MHz  |
| $F_{REF\_EXT}$  | External clock reference <sup>a</sup> | 3.579545           | -   | 16.384            | MHz  |
| $F_{PLL}$       | PLL frequency <sup>b</sup>            | -                  | 400 | -                 | MHz  |
| $T_{READY}$     | PLL lock time                         | 0.562 <sup>c</sup> | -   | 1.38 <sup>d</sup> | ms   |

a. The exact value is determined by the crystal value programmed into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

c. Using a 16.384-MHz crystal

d. Using 3.5795-MHz crystal

Table 25-8 on page 1219 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

**Table 25-8. Actual PLL Frequency**

| XTAL | Crystal Frequency (MHz) | PLL Frequency (MHz) | Error   |
|------|-------------------------|---------------------|---------|
| 0x04 | 3.5795                  | 400.904             | 0.0023% |
| 0x05 | 3.6864                  | 398.1312            | 0.0047% |
| 0x06 | 4.0                     | 400                 | -       |
| 0x07 | 4.096                   | 401.408             | 0.0035% |
| 0x08 | 4.9152                  | 398.1312            | 0.0047% |
| 0x09 | 5.0                     | 400                 | -       |
| 0x0A | 5.12                    | 399.36              | 0.0016% |
| 0x0B | 6.0                     | 400                 | -       |
| 0x0C | 6.144                   | 399.36              | 0.0016% |
| 0x0D | 7.3728                  | 398.1312            | 0.0047% |
| 0x0E | 8.0                     | 400                 | -       |
| 0x0F | 8.192                   | 398.6773333         | 0.0033% |
| 0x10 | 10.0                    | 400                 | -       |
| 0x11 | 12.0                    | 400                 | -       |
| 0x12 | 12.288                  | 401.408             | 0.0035% |
| 0x13 | 13.56                   | 397.76              | 0.0056% |
| 0x14 | 14.318                  | 400.90904           | 0.0023% |
| 0x15 | 16.0                    | 400                 | -       |
| 0x16 | 16.384                  | 404.1386667         | 0.010%  |

## 25.8.2 PIOSC Specifications

**Table 25-9. PIOSC Clock Characteristics**

| Parameter              | Parameter Name                                                                                                           | Min | Nom    | Max | Unit |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|-----|--------|-----|------|
| F <sub>PIOSC25</sub>   | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C                                     | -   | ±0.25% | ±1% | -    |
| F <sub>PIOSCT</sub>    | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C, across specified temperature range | -   | -      | ±3% | -    |
| F <sub>PIOSCUCAL</sub> | Internal 16-MHz precision oscillator frequency variance, user calibrated at a chosen temperature                         | -   | ±0.25% | ±1% | -    |

## 25.8.3 Internal 30-kHz Oscillator Specifications

**Table 25-10. 30-kHz Clock Characteristics**

| Parameter              | Parameter Name                       | Min | Nom | Max | Unit |
|------------------------|--------------------------------------|-----|-----|-----|------|
| F <sub>IOSC30KHZ</sub> | Internal 30-KHz oscillator frequency | 15  | 30  | 45  | KHz  |

## 25.8.4 Hibernation Clock Source Specifications

**Table 25-11. Hibernation Clock Characteristics**

| Parameter                 | Parameter Name                                   | Min | Nom      | Max | Unit |
|---------------------------|--------------------------------------------------|-----|----------|-----|------|
| F <sub>HIBOSC</sub>       | Hibernation module oscillator frequency          | -   | 4.194304 | -   | MHz  |
| F <sub>HIBOSC_XTAL</sub>  | Crystal reference for hibernation oscillator     | -   | 4.194304 | -   | MHz  |
| T <sub>HIBOSC_START</sub> | Hibernation oscillator startup time <sup>a</sup> | -   | -        | 10  | ms   |
| F <sub>HIBOSC_EXT</sub>   | External clock reference for hibernation module  | -   | 32.768   | -   | KHz  |
| DC <sub>HIBOSC_EXT</sub>  | External clock reference duty cycle              | 45  | -        | 55  | %    |

a. This parameter is highly sensitive to PCB layout and trace lengths, which may make this parameter time longer. Care must be taken in PCB design to minimize trace lengths and RLC (resistance, inductance, capacitance).

**Table 25-12. HIB Oscillator Input Characteristics**

| Parameter             | Parameter Name                             | Min | Nom                                          | Max | Unit |
|-----------------------|--------------------------------------------|-----|----------------------------------------------|-----|------|
| F <sub>HIBOSC</sub>   | Hibernation module oscillator frequency    | -   | 4.194304                                     | -   | MHz  |
| TOL <sub>HIBOSC</sub> | Hibernation oscillator frequency tolerance | -   | Defined by customer application requirements | -   | PPM  |

## 25.8.5 Main Oscillator Specifications

**Table 25-13. Main Oscillator Clock Characteristics**

| Parameter                    | Parameter Name                                                                | Min  | Nom | Max    | Unit |
|------------------------------|-------------------------------------------------------------------------------|------|-----|--------|------|
| F <sub>MOSC</sub>            | Main oscillator frequency                                                     | 1    | -   | 16.384 | MHz  |
| T <sub>MOSC_PER</sub>        | Main oscillator period                                                        | 61   | -   | 1000   | ns   |
| T <sub>MOSC_SETTLE</sub>     | Main oscillator settling time <sup>a</sup>                                    | 17.5 | -   | 20     | ms   |
| F <sub>REF_XTAL_BYPASS</sub> | Crystal reference using the main oscillator (PLL in BYPASS mode) <sup>b</sup> | 1    | -   | 16.384 | MHz  |
| F <sub>REF_EXT_BYPASS</sub>  | External clock reference (PLL in BYPASS mode) <sup>b</sup>                    | 0    | -   | 50     | MHz  |
| DC <sub>MOSC_EXT</sub>       | External clock reference duty cycle                                           | 45   | -   | 55     | %    |

a. This parameter is highly sensitive to PCB layout and trace lengths, which may make this parameter time longer. Care must be taken in PCB design to minimize trace lengths and RLC (resistance, inductance, capacitance).

b. If the ADC is used, the crystal reference must be 16 MHz  $\pm$  .03% when the PLL is bypassed.

**Table 25-14. Supported MOSC Crystal Frequencies<sup>a</sup>**

| Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL |
|-------------------------------------------|---------------------------------------|
| 1.000 MHz                                 | reserved                              |
| 1.8432 MHz                                | reserved                              |
| 2.000 MHz                                 | reserved                              |
| 2.4576 MHz                                | reserved                              |
| 3.579545 MHz                              |                                       |

| 4 MHz (USB)                               |                                       |
| 4.096 MHz                                 |                                       |

Table 25-14. Supported MOSC Crystal Frequencies (continued)

| Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL |
|-------------------------------------------|---------------------------------------|
| 4.9152 MHz                                |                                       |
| 5 MHz (USB)                               |                                       |
| 5.12 MHz                                  |                                       |
| 6 MHz (reset value)(USB)                  |                                       |
| 6.144 MHz                                 |                                       |
| 7.3728 MHz                                |                                       |
| 8 MHz (USB)                               |                                       |
| 8.192 MHz                                 |                                       |
| 10.0 MHz (USB)                            |                                       |
| 12.0 MHz (USB)                            |                                       |
| 12.288 MHz                                |                                       |
| 13.56 MHz                                 |                                       |
| 14.31818 MHz                              |                                       |
| 16.0 MHz (USB)                            |                                       |
| 16.384 MHz                                |                                       |

a. Frequencies that may be used with the USB interface are indicated in the table.

## 25.8.6 System Clock Specification with ADC Operation

Table 25-15. System Clock Characteristics with ADC Operation

| Parameter           | Parameter Name                                                                               | Min     | Nom | Max     | Unit |
|---------------------|----------------------------------------------------------------------------------------------|---------|-----|---------|------|
| $F_{\text{sysadc}}$ | System clock frequency when the ADC module is operating (when PLL is bypassed). <sup>a</sup> | 15.9952 | 16  | 16.0048 | MHz  |

a. Clock frequency (plus jitter) must be stable inside specified range. ADC can be clocked from the PLL or directly from an external clock source, as long as frequency absolute precision is inside specified range.

## 25.8.7 System Clock Specification with USB Operation

Table 25-16. System Clock Characteristics with USB Operation

| Parameter           | Parameter Name                                                                                                                          | Min | Nom | Max | Unit |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----|-----|-----|------|
| $F_{\text{sysusb}}$ | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 30  | -   | -   | MHz  |

## 25.9 Sleep Modes

Table 25-17. Sleep Modes AC Characteristics<sup>a</sup>

| Parameter No | Parameter                 | Parameter Name                                                                          | Min | Nom | Max                | Unit          |
|--------------|---------------------------|-----------------------------------------------------------------------------------------|-----|-----|--------------------|---------------|
| D1           | $T_{\text{WAKE\_S}}$      | Time to wake from interrupt in sleep mode, not using the PLL <sup>b</sup>               | -   | -   | 2                  | system clocks |
|              | $T_{\text{WAKE\_DS}}$     | Time to wake from interrupt deep-sleep mode, not using the PLL <sup>b</sup>             | -   | -   | 7                  | system clocks |
| D2           | $T_{\text{WAKE\_PLL\_S}}$ | Time to wake from interrupt in sleep or deep-sleep mode when using the PLL <sup>b</sup> | -   | -   | $T_{\text{READY}}$ | ms            |

Table 25-17. Sleep Modes AC Characteristics (continued)

| Parameter No | Parameter             | Parameter Name                                   | Min | Nom | Max             | Unit |
|--------------|-----------------------|--------------------------------------------------|-----|-----|-----------------|------|
| D3           | T <sub>ENTER_DS</sub> | Time to enter deep-sleep mode from sleep request | -   | 0   | 35 <sup>c</sup> | ms   |

a. Values in this table assume the IOSC is the clock source during sleep or deep-sleep mode.

b. Specified from registering the interrupt to first instruction.

c. Nominal specification occurs 99.9995% of the time.

## 25.10 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 301.

Table 25-18. Hibernation Module Battery Characteristics

| Parameter           | Parameter Name             | Min | Nominal | Max | Unit |
|---------------------|----------------------------|-----|---------|-----|------|
| V <sub>BAT</sub>    | Battery supply voltage     | 2.4 | 3.0     | 3.6 | V    |
| V <sub>LOWBAT</sub> | Low battery detect voltage | 1.8 | -       | 2.2 | V    |

Table 25-19. Hibernation Module AC Characteristics

| Parameter No | Parameter                   | Parameter Name                                                                                                       | Min | Nom | Max             | Unit |
|--------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------|-----|-----|-----------------|------|
| H1           | T <sub>HIB_LOW</sub>        | Internal 32.768 KHz clock reference rising edge to HIB asserted                                                      | 20  | -   | -               | μs   |
| H2           | T <sub>HIB_HIGH</sub>       | Internal 32.768 KHz clock reference rising edge to HIB deasserted                                                    | -   | 30  | -               | μs   |
| H3           | T <sub>WAKE_TO_HIB</sub>    | WAKE assert to HIB desassert (wake up time), internal Hibernation oscillator running during hibernation <sup>a</sup> | 62  | -   | 124             | μs   |
| H4           | T <sub>WAKE_TO_HIB</sub>    | WAKE assert to HIB desassert (wake up time), internal Hibernation oscillator stopped during hibernation <sup>a</sup> | -   | -   | 10              | ms   |
| H5           | T <sub>WAKE_CLOCK</sub>     | WAKE assertion time, internal Hibernation oscillator running during hibernation                                      | 62  | -   | -               | μs   |
| H6           | T <sub>WAKE_NOCLOCK</sub>   | WAKE assertion time, internal Hibernation oscillator stopped during hibernation <sup>b</sup>                         | 10  | -   | -               | ms   |
| H7           | T <sub>HIB_REG_ACCESS</sub> | Time required for a write to a non-volatile register in the HIB module to complete                                   | 92  | -   | -               | μs   |
| H8           | T <sub>HIB_TO_HIB</sub>     | HIB high time between assertions                                                                                     | 100 | -   | -               | ms   |
| H9           | T <sub>ENTER_HIB</sub>      | Time to enter Hibernate mode from hibernation request                                                                | -   | 0   | 35 <sup>c</sup> | ms   |

a. Code begins executing after the time period specified by T<sub>IRPOR</sub> following the deassertion of HIB.

b. This mode is used when the PINWEN bit is set and the RTCEN bit is clear in the HIBCTL register.

c. Nominal specification occurs 99.998% of the time.

**Figure 25-11. Hibernation Module Timing with Internal Oscillator Running in Hibernation****Figure 25-12. Hibernation Module Timing with Internal Oscillator Stopped in Hibernation**

## 25.11 Flash Memory

**Table 25-20. Flash Memory Characteristics**

| Parameter          | Parameter Name                                                        | Min    | Nom | Max | Unit   |
|--------------------|-----------------------------------------------------------------------|--------|-----|-----|--------|
| PE <sub>CYC</sub>  | Number of guaranteed program/erase cycles before failure <sup>a</sup> | 15,000 | -   | -   | cycles |
| T <sub>RET</sub>   | Data retention, -40°C to +85°C                                        | 10     | -   | -   | years  |
| T <sub>PROG</sub>  | Word program time                                                     | -      | -   | 1   | ms     |
| T <sub>BPROG</sub> | Buffer program time                                                   | -      | -   | 1   | ms     |
| T <sub>ERASE</sub> | Page erase time                                                       | -      | -   | 12  | ms     |
| T <sub>ME</sub>    | Mass erase time                                                       | -      | -   | 16  | ms     |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

## 25.12 Input/Output Characteristics

**Note:** All GPIO signals are 5-V tolerant when configured as inputs except for PB0 and PB1, which are limited to 3.6 V. See “Signal Description” on page 423 for more information on GPIO configuration.

**Table 25-21. GPIO Module Characteristics<sup>a</sup>**

| Parameter           | Parameter Name                          | Min | Nom | Max | Unit |
|---------------------|-----------------------------------------|-----|-----|-----|------|
| R <sub>GPIOPU</sub> | GPIO internal pull-up resistor          | 100 | -   | 300 | kΩ   |
| R <sub>GPIOPD</sub> | GPIO internal pull-down resistor        | 200 | -   | 500 | kΩ   |
| I <sub>LKG</sub>    | GPIO input leakage current <sup>b</sup> | -   | -   | 2   | μA   |

Table 25-21. GPIO Module Characteristics (continued)

| Parameter   | Parameter Name                                                 | Min | Nom | Max | Unit |
|-------------|----------------------------------------------------------------|-----|-----|-----|------|
| $T_{GPIOR}$ | GPIO rise time, 2-mA drive <sup>c</sup>                        | -   | 14  | 20  | ns   |
|             | GPIO rise time, 4-mA drive <sup>c</sup>                        |     | 7   | 10  | ns   |
|             | GPIO rise time, 8-mA drive <sup>c</sup>                        |     | 4   | 5   | ns   |
|             | GPIO rise time, 8-mA drive with slew rate control <sup>c</sup> |     | 6   | 8   | ns   |
| $T_{GPIOF}$ | GPIO fall time, 2-mA drive <sup>d</sup>                        | -   | 14  | 21  | ns   |
|             | GPIO fall time, 4-mA drive <sup>d</sup>                        |     | 7   | 11  | ns   |
|             | GPIO fall time, 8-mA drive <sup>d</sup>                        |     | 4   | 6   | ns   |
|             | GPIO fall time, 8-mA drive with slew rate control <sup>d</sup> |     | 6   | 8   | ns   |

a.  $V_{DD}$  must be within the range specified in Table 25-2 on page 1213.

b. The leakage current is measured with GND or  $V_{DD}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pullup/pulldown resistor is disabled.

c. Time measured from 20% to 80% of  $V_{DD}$ .

d. Time measured from 80% to 20% of  $V_{DD}$ .

## 25.13 External Peripheral Interface (EPI)

When the EPI module is in SDRAM mode, the drive strength must be configured to 8 mA. Table 25-22 on page 1224 shows the rise and fall times in SDRAM mode with 16 pF load conditions. When the EPI module is in Host-Bus or General-Purpose mode, the values in “Input/Output Characteristics” on page 1223 should be used.

Table 25-22. EPI SDRAM Characteristics

| Parameter    | Parameter Name                               | Condition                 | Min | Nom | Max | Unit |
|--------------|----------------------------------------------|---------------------------|-----|-----|-----|------|
| $T_{SDRAMR}$ | EPI Rise Time (from 20% to 80% of $V_{DD}$ ) | 8-mA drive, $C_L = 16$ pF | -   | 2   | 3   | ns   |
| $T_{SDRAMF}$ | EPI Fall Time (from 80% to 20% of $V_{DD}$ ) | 8-mA drive, $C_L = 16$ pF | -   | 2   | 3   | ns   |

Table 25-23. EPI SDRAM Interface Characteristics<sup>a</sup>

| Parameter No | Parameter | Parameter Name         | Min | Nom | Max | Unit |
|--------------|-----------|------------------------|-----|-----|-----|------|
| E1           | $T_{CK}$  | SDRAM Clock period     | 20  | -   | -   | ns   |
| E2           | $T_{CH}$  | SDRAM Clock high time  | 10  | -   | -   | ns   |
| E3           | $T_{CL}$  | SDRAM Clock low time   | 10  | -   | -   | ns   |
| E4           | $T_{COV}$ | CLK to output valid    | -5  | -   | 5   | ns   |
| E5           | $T_{COI}$ | CLK to output invalid  | -5  | -   | 5   | ns   |
| E6           | $T_{COT}$ | CLK to output tristate | -5  | -   | 5   | ns   |
| E7           | $T_S$     | Input set up to CLK    | 10  | -   | -   | ns   |
| E8           | $T_H$     | CLK to input hold      | 0   | -   | -   | ns   |
| E9           | $T_{PU}$  | Power-up time          | 100 | -   | -   | μs   |
| E10          | $T_{RP}$  | Precharge all banks    | 20  | -   | -   | ns   |
| E11          | $T_{RFC}$ | Auto refresh           | 66  | -   | -   | ns   |
| E12          | $T_{MRD}$ | Program mode register  | 40  | -   | -   | ns   |

a. The EPI SDRAM interface must use 8-mA drive.

Figure 25-13. SDRAM Initialization and Load Mode Register Timing

Figure 25-14. SDRAM Read Timing

Figure 25-15. SDRAM Write Timing

Table 25-24. EPI Host-Bus 8 and Host-Bus 16 Interface Characteristics

| Parameter No | Parameter     | Parameter Name                            | Min | Nom | Max | Unit          |
|--------------|---------------|-------------------------------------------|-----|-----|-----|---------------|
| E14          | $T_{ISU}$     | Read data set up time                     | 10  | -   | -   | ns            |
| E15          | $T_{IH}$      | Read data hold time                       | 0   | -   | -   | ns            |
| E16          | $T_{DV}$      | WEn to write data valid                   | -   | -   | 5   | ns            |
| E17          | $T_{DI}$      | Data hold from WEn invalid                | 2   | -   | -   | EPI Clocks    |
| E18          | $T_{OV}$      | CSn to output valid                       | -5  | -   | 5   | ns            |
| E19          | $T_{OINV}$    | CSn to output invalid                     | -5  | -   | 5   | ns            |
| E20          | $T_{STLOW}$   | WEn / RDn strobe width low                | 2   | -   | -   | EPI Clocks    |
| E21          | $T_{FIFO}$    | FEMPTY and FFULL setup time to clock edge | 2   | -   | -   | System Clocks |
| E22          | $T_{ALEHIGH}$ | ALE width high                            | -   | 1   | -   | EPI Clocks    |

## 25.14 Analog-to-Digital Converter (ADC)

Table 25-26. ADC Characteristics<sup>a</sup>

| Parameter            | Parameter Name                                                                  | Min     | Nom | Max                 | Unit               |
|----------------------|---------------------------------------------------------------------------------|---------|-----|---------------------|--------------------|
| $V_{\text{ADCIN}}$   | Maximum single-ended, full-scale analog input voltage, using internal reference | -       | -   | 3.0                 | V                  |
|                      | Maximum single-ended, full-scale analog input voltage, using external reference | -       | -   | $V_{\text{REFA}}$   | V                  |
|                      | Minimum single-ended, full-scale analog input voltage                           | 0.0     | -   | -                   | V                  |
|                      | Maximum differential, full-scale analog input voltage, using internal reference | -       | -   | 1.5                 | V                  |
|                      | Maximum differential, full-scale analog input voltage, using external reference | -       | -   | $V_{\text{REFA}}/2$ | V                  |
|                      | Minimum differential, full-scale analog input voltage                           | 0.0     | -   | -                   | V                  |
| N                    | Resolution                                                                      | 10      |     |                     | bits               |
| $F_{\text{ADC}}$     | ADC internal clock frequency <sup>b</sup>                                       | 15.9952 | 16  | 16.0048             | MHz                |
| $T_{\text{ADCCONV}}$ | Conversion time <sup>c</sup>                                                    | 1       |     |                     | $\mu\text{s}$      |
| $F_{\text{ADCCONV}}$ | Conversion rate <sup>c</sup>                                                    | 1000    |     |                     | k samples/s        |
| $T_{\text{ADCSAMP}}$ | Sample time                                                                     | 187.5   | -   | -                   | ns                 |
| $T_{\text{LT}}$      | Latency from trigger to start of conversion                                     | -       | 2   | -                   | system clocks      |
| $I_{\text{L}}$       | ADC input leakage                                                               | -       | -   | 2.0                 | $\mu\text{A}$      |
| $R_{\text{ADC}}$     | ADC equivalent resistance                                                       | -       | -   | 10                  | k $\Omega$         |
| $C_{\text{ADC}}$     | ADC equivalent capacitance                                                      | 0.9     | 1.0 | 1.1                 | pF                 |
| $E_{\text{L}}$       | Integral nonlinearity (INL) error                                               | -       | -   | $\pm 3$             | LSB                |
| $E_{\text{D}}$       | Differential nonlinearity (DNL) error                                           | -       | -   | $\pm 3$             | LSB                |
| $E_{\text{O}}$       | Offset error                                                                    | -       | -   | $\pm 20$            | LSB                |
| $E_{\text{G}}$       | Full-scale gain error                                                           | -       | -   | $\pm 30$            | LSB                |
| $E_{\text{TS}}$      | Temperature sensor accuracy <sup>d</sup>                                        | -       | -   | $\pm 5$             | $^{\circ}\text{C}$ |

a. The ADC reference voltage is 3.0 V. This reference voltage is internally generated from the 3.3 VDDA supply by a band gap circuit.

b. The ADC must be clocked from the PLL or directly from an external clock source to operate properly.

c. The conversion time and rate scale from the specified number if the ADC internal clock frequency is any value other than 16 MHz.

d. Note that this parameter does not include ADC error.

Figure 25-22. ADC Input Equivalency Diagram

Table 25-27. ADC Module External Reference Characteristics<sup>a</sup>

| Parameter         | Parameter Name                                  | Min  | Nom | Max  | Unit          |
|-------------------|-------------------------------------------------|------|-----|------|---------------|
| $V_{\text{REFA}}$ | External voltage reference for ADC <sup>b</sup> | 2.97 | -   | 3.03 | V             |
| $I_L$             | External voltage reference leakage current      | -    | -   | 2.0  | $\mu\text{A}$ |

a. Care must be taken to supply a reference voltage of acceptable quality.

b. Ground is always used as the reference level for the minimum conversion value.

Table 25-28. ADC Module Internal Reference Characteristics

| Parameter         | Parameter Name                     | Min | Nom | Max | Unit |
|-------------------|------------------------------------|-----|-----|-----|------|
| $V_{\text{REFI}}$ | Internal voltage reference for ADC | -   | 3.0 | -   | V    |

## 25.15 Synchronous Serial Interface (SSI)

Table 25-29. SSI Characteristics

| Parameter No. | Parameter              | Parameter Name                     | Min | Nom | Max | Unit          |
|---------------|------------------------|------------------------------------|-----|-----|-----|---------------|
| S1            | $T_{\text{CLK\_PER}}$  | SSIClk cycle time <sup>a</sup>     | 40  | -   | -   | ns            |
| S2            | $T_{\text{CLK\_HIGH}}$ | SSIClk high time                   | -   | 0.5 | -   | t clk_per     |
| S3            | $T_{\text{CLK\_LOW}}$  | SSIClk low time                    | -   | 0.5 | -   | t clk_per     |
| S4            | $T_{\text{CLKRF}}$     | SSIClk rise/fall time <sup>b</sup> | -   | 4   | 6   | ns            |
| S5            | $T_{\text{DMD}}$       | Data from master valid delay time  | 0   | -   | 1   | system clocks |
| S6            | $T_{\text{DMS}}$       | Data from master setup time        | 1   | -   | -   | system clocks |
| S7            | $T_{\text{DMH}}$       | Data from master hold time         | 2   | -   | -   | system clocks |
| S8            | $T_{\text{DSS}}$       | Data from slave setup time         | 1   | -   | -   | system clocks |
| S9            | $T_{\text{DSH}}$       | Data from slave hold time          | 2   | -   | -   | system clocks |

a. In master mode, the system clock must be at least twice as fast as the SSIClk; in slave mode, the system clock must be at least 12 times faster than the SSIClk.

b. Note that the delays shown are using 8-mA drive strength.

## 25.16 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

Table 25-30. I<sup>2</sup>C Characteristics

| Parameter No.   | Parameter         | Parameter Name                                                               | Min | Nom | Max          | Unit          |
|-----------------|-------------------|------------------------------------------------------------------------------|-----|-----|--------------|---------------|
| 11 <sup>a</sup> | T <sub>SCH</sub>  | Start condition hold time                                                    | 36  | -   | -            | system clocks |
| 12 <sup>a</sup> | T <sub>LP</sub>   | Clock Low period                                                             | 36  | -   | -            | system clocks |
| 13 <sup>b</sup> | T <sub>SRT</sub>  | I2CSCL/I2CSDA rise time (V <sub>IL</sub> = 0.5 V to V <sub>IH</sub> = 2.4 V) | -   | -   | (see note b) | ns            |
| 14 <sup>a</sup> | T <sub>DH</sub>   | Data hold time                                                               | 2   | -   | -            | system clocks |
| 15 <sup>c</sup> | T <sub>SFT</sub>  | I2CSCL/I2CSDA fall time (V <sub>IH</sub> = 2.4 V to V <sub>IL</sub> = 0.5 V) | -   | 9   | 10           | ns            |
| 16 <sup>a</sup> | T <sub>HT</sub>   | Clock High time                                                              | 24  | -   | -            | system clocks |
| 17 <sup>a</sup> | T <sub>DS</sub>   | Data setup time                                                              | 18  | -   | -            | system clocks |
| 18 <sup>a</sup> | T <sub>SCSR</sub> | Start condition setup time (for repeated start condition only)               | 36  | -   | -            | system clocks |
| 19 <sup>a</sup> | T <sub>SCS</sub>  | Stop condition setup time                                                    | 24  | -   | -            | system clocks |

a. Values depend on the value programmed into the TPR bit in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register; a TPR programmed for the maximum I2CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I2CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.

b. Because I2CSCL and I2CSDA operate as open-drain-type signals, which the controller can only actively drive Low, the time I2CSCL or I2CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.

c. Specified at a nominal 50 pF load.

Figure 25-26. I<sup>2</sup>C Timing

## 25.17 Inter-Integrated Circuit Sound (I<sup>2</sup>S) Interface

Table 25-31. I<sup>2</sup>S Master Clock (Receive and Transmit)

| Parameter No. | Parameter              | Parameter Name | Min                                              | Nom | Max | Unit |
|---------------|------------------------|----------------|--------------------------------------------------|-----|-----|------|
| M1            | T <sub>MCLK_PER</sub>  | Cycle time     | 20.3                                             | -   | -   | ns   |

## 25.18 Ethernet Controller

Table 25-35. Ethernet Controller DC Characteristics

| Parameter          | Parameter Name                                    | Value       | Unit |
|--------------------|---------------------------------------------------|-------------|------|
| R <sub>EBIAS</sub> | Value of the pull-down resistor on the ERBIAS pin | 12.4K ± 1 % | Ω    |

**Table 25-36. 100BASE-TX Transmitter Characteristics<sup>a</sup>**

| Parameter Name            | Min | Nom | Max  | Unit |
|---------------------------|-----|-----|------|------|
| Peak output amplitude     | 950 | -   | 1050 | mVpk |
| Output amplitude symmetry | 98  | -   | 102  | %    |
| Output overshoot          | -   | -   | 5    | %    |
| Rise/Fall time            | 3   | -   | 5    | ns   |
| Rise/Fall time imbalance  | -   | -   | 500  | ps   |
| Duty cycle distortion     | -   | -   | ±250 | ps   |
| Jitter                    | -   | -   | 1.4  | ns   |

a. Measured at the line side of the transformer.

**Table 25-37. 100BASE-TX Transmitter Characteristics (informative)<sup>a</sup>**

| Parameter Name          | Min | Nom | Max | Unit |
|-------------------------|-----|-----|-----|------|
| Return loss             | 16  | -   | -   | dB   |
| Open-circuit inductance | 350 | -   | -   | μH   |

a. The specifications in this table are included for information only. They are mainly a function of the external transformer and termination resistors used for measurements.

**Table 25-38. 100BASE-TX Receiver Characteristics**

| Parameter Name                       | Min | Nom | Max  | Unit  |
|--------------------------------------|-----|-----|------|-------|
| Signal detect assertion threshold    | 600 | 700 | -    | mVppd |
| Signal detect de-assertion threshold | 350 | 425 | -    | mVppd |
| Differential input resistance        | -   | 3.6 | -    | kΩ    |
| Jitter tolerance (pk-pk)             | 4   | -   | -    | ns    |
| Baseline wander tracking             | -80 | -   | +80  | %     |
| Signal detect assertion time         | -   | -   | 1000 | μs    |
| Signal detect de-assertion time      | -   | -   | 4    | μs    |

**Table 25-39. 10BASE-T Transmitter Characteristics<sup>a</sup>**

| Parameter Name                        | Min | Nom | Max | Unit |
|---------------------------------------|-----|-----|-----|------|
| Peak differential output signal       | 2.2 | -   | 2.7 | V    |
| Harmonic content                      | 27  | -   | -   | dB   |
| Link pulse width                      | -   | 100 | -   | ns   |
| Start-of-idle pulse width, Last bit 0 | -   | 300 | -   | ns   |
| Start-of-idle pulse width, Last bit 1 | -   | 350 | -   | ns   |

a. The Manchester-encoded data pulses, the link pulse and the start-of-idle pulse are tested against the templates and using the procedures found in Clause 14 of *IEEE 802.3*.

**Table 25-40. 10BASE-T Transmitter Characteristics (informative)<sup>a</sup>**

| Parameter Name                  | Min            | Nom | Max | Unit |
|---------------------------------|----------------|-----|-----|------|
| Output return loss              | 15             | -   | -   | dB   |
| Output impedance balance        | 29-17log(f/10) | -   | -   | dB   |
| Peak common-mode output voltage | -              | -   | 50  | mV   |
| Common-mode rejection           | -              | -   | 100 | mV   |

**Table 25-40. 10BASE-T Transmitter Characteristics (informative) (continued)**

| Parameter Name               | Min | Nom | Max | Unit |
|------------------------------|-----|-----|-----|------|
| Common-mode rejection jitter | -   | -   | 1   | ns   |

a. The specifications in this table are included for information only. They are mainly a function of the external transformer and termination resistors used for measurements.

**Table 25-41. 10BASE-T Receiver Characteristics**

| Parameter Name                | Min | Nom | Max | Unit  |
|-------------------------------|-----|-----|-----|-------|
| Jitter tolerance (pk-pk)      | 30  | 26  | -   | ns    |
| Input squelched threshold     | 340 | 440 | 540 | mVppd |
| Differential input resistance | -   | 3.6 | -   | kΩ    |
| Common-mode rejection         | 25  | -   | -   | V     |

**Table 25-42. Isolation Transformers<sup>a</sup>**

| Name                      | Value         | Condition       |
|---------------------------|---------------|-----------------|
| Turns ratio               | 1 CT : 1 CT   | +/- 5%          |
| Open-circuit inductance   | 350 uH (min)  | @ 10 mV, 10 kHz |
| Leakage inductance        | 0.40 uH (max) | @ 1 MHz (min)   |
| Inter-winding capacitance | 25 pF (max)   |                 |
| DC resistance             | 0.9 Ohm (max) |                 |
| Insertion loss            | 0.4 dB (typ)  | 0-65 MHz        |
| HIPOT                     | 1500          | Vrms            |

a. Two simple 1:1 isolation transformers are required at the line interface. Transformers with integrated common-mode chokes are recommended for exceeding FCC requirements. This table gives the recommended line transformer characteristics.

**Note:** The 100Base-TX amplitude specifications assume a transformer loss of 0.4 dB.

**Table 25-43. Ethernet Reference Crystal**

| Parameter                  | Parameter Name                                           | Min                                  | Nom | Max | Unit |
|----------------------------|----------------------------------------------------------|--------------------------------------|-----|-----|------|
| F <sub>XTALPHYOSC</sub>    | Ethernet PHY oscillator frequency                        | -                                    | 25  | -   | MHz  |
| TOL <sub>XTALPHYOSC</sub>  | Ethernet PHY oscillator frequency tolerance <sup>a</sup> | -                                    | ±50 | -   | PPM  |
| MODE <sub>XTALPHYOSC</sub> | Ethernet PHY oscillation mode                            | Parallel resonance, fundamental mode |     |     | -    |

a. This tolerance provides a guard band for temperature stability and aging drift.

Figure 25-31. External XTLP Oscillator Characteristics

Table 25-44. External XTLP Oscillator Characteristics

| Parameter                       | Parameter Name              | Min      | Nom  | Max      | Unit |

| T <sub>R</sub> , T <sub>F</sub> | Rise/Fall Time              | -        | -    | 4.0      | ns   |
| T <sub>JITTER</sub>             | Absolute Jitter             | -        | -    | 0.1      | ns   |

a. IEEE 802.3 frequency tolerance  $\pm 50$  ppm.

## 25.19 Universal Serial Bus (USB) Controller

The Stellaris<sup>®</sup> USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the LM3S9B90 microcontroller and specific to the Stellaris microcontroller design. An external component resistor is needed as specified in Table 25-45.

Table 25-45. USB Controller Characteristics

| Parameter          | Parameter Name                                       | Value          | Unit     |
|--------------------|------------------------------------------------------|----------------|----------|
| R <sub>UBIAS</sub> | Value of the pull-down resistor on the USB0RBIAS pin | 9.1K $\pm$ 1 % | $\Omega$ |

## 25.20 Analog Comparator

Table 25-46. Analog Comparator Characteristics

| Parameter                           | Parameter Name                  | Min | Nom      | Max                  | Unit |
|-------------------------------------|---------------------------------|-----|----------|----------------------|------|

| A <sub>LR</sub> | Absolute accuracy low range  | -   | -                    | ±R <sub>LR</sub> /4 | V    |

## 25.21 Current Consumption

This section provides information on typical and maximum power consumption under various conditions. Unless otherwise indicated, current consumption numbers include use of the on-chip LDO regulator and therefore include I<sub>DDC</sub>.

### 25.21.1 Nominal Power Consumption

The following table provides nominal figures for current consumption.

**Table 25-48. Nominal Power Consumption**

| Parameter                 | Parameter Name                                                              | Conditions                                                                                                                                             | Nom                                  | Unit |
|---------------------------|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|------|
| I <sub>DD_RUN</sub>       | Run mode 1 (Flash loop)                                                     | V <sub>DD</sub> = 3.3 V<br>Code= while(1){} executed out of Flash<br>Peripherals = All ON<br>System Clock = 80 MHz (with PLL)<br>Temp = 25°C           | 101 <sup>a</sup><br>159 <sup>b</sup> | mA   |
| I <sub>DD_SLEEP</sub>     | Sleep mode                                                                  | V <sub>DD</sub> = 3.3 V<br>Peripherals = All clock gated<br>System Clock = 80 MHz (with PLL)<br>Temp = 25°C                                            | 20                                   | mA   |
| I <sub>DD_DEEPSLEEP</sub> | Deep-sleep mode                                                             | Peripherals = All OFF<br>System Clock = IOS30KHZ/64<br>Temp = 25°C                                                                                     | 550                                  | μA   |
| I <sub>HIB_NORTC</sub>    | Hibernate mode (external wake, RTC disabled, I/O not powered <sup>c</sup> ) | V <sub>BAT</sub> = 3.0 V<br>V <sub>DD</sub> = 0 V<br>V <sub>DDA</sub> = 0 V<br>Peripherals = All OFF<br>System Clock = OFF<br>Hibernate Module = 0 kHz | 30                                   | μA   |

Table 25-48. Nominal Power Consumption (*continued*)

| Parameter      | Parameter Name                                              | Conditions                                                                                                                                              | Nom | Unit          |
|----------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------------|
| $I_{HIB\_RTC}$ | Hibernate mode (RTC enabled, I/O not powered <sup>c</sup> ) | $V_{BAT} = 3.0\text{ V}$<br>$V_{DD} = 0\text{ V}$<br>$V_{DDA} = 0\text{ V}$<br>Peripherals = All OFF<br>System Clock = OFF<br>Hibernate Module = 32 kHz | 44  | $\mu\text{A}$ |

a. Ethernet MAC and PHY powered down by software.

b. Auto-negotiate enabled. If an Ethernet cable is attached to the connector, the consumption increases by 7-10 mA.

c. The VDD3ON mode must be disabled for the I/O ring to be unpowered.

## 25.21.2 Maximum Current Consumption

The current measurements specified in the table that follows are maximum values under the following conditions:

- $V_{DD} = 3.6\text{ V}$
- $V_{DDC} = 1.3\text{ V}$
- $V_{BAT} = 3.25\text{ V}$
- $V_{DDA} = 3.6\text{ V}$
- Temperature = 85°C
- Clock source (MOSC) = 16.348-MHz crystal oscillator

Table 25-49. Detailed Current Specifications

| Parameter     | Parameter Name          | Conditions                                                                                                                                           | Max                                  | Unit |
|---------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|------|

## B Ordering and Contact Information

### B.1 Ordering Information

**Table B-1. Part Ordering Information<sup>a</sup>**

| Orderable Part Number | Description                                                                          |
|-----------------------|--------------------------------------------------------------------------------------|
| LM3S9B90-IQC80-C5     | Stellaris® LM3S9B90 Microcontroller Industrial Temperature 100-pin LQFP              |
| LM3S9B90-IBZ80-C5     | Stellaris LM3S9B90 Microcontroller Industrial Temperature 108-ball BGA               |
| LM3S9B90-IQC80-C5T    | Stellaris LM3S9B90 Microcontroller Industrial Temperature 100-pin LQFP Tape-and-reel |
| LM3S9B90-IBZ80-C5T    | Stellaris LM3S9B90 Microcontroller Industrial Temperature 108-ball BGA Tape-and-reel |

a. NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

### B.2 Part Markings

The Stellaris microcontrollers are marked with an identifying number. This code contains the following information:

- The first line indicates the part number, for example, LM3S9B90.
- In the second line, the first eight characters indicate the temperature, package, speed, revision, and product status. For example in the figure below, IQC80C0X indicates an Industrial temperature (I), 100-pin LQFP package (QC), 80-MHz (80), revision C0 (C0) device. The letter immediately following the revision indicates product status. An X indicates experimental and requires a waiver; an S indicates the part is fully qualified and released to production.
- The remaining characters contain internal tracking numbers.

## B.3 Kits

The Stellaris Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the website at [www.ti.com/stellaris](http://www.ti.com/stellaris) for the latest tools available, or ask your distributor.

## B.4 Support Information

For support on Stellaris products, contact the TI Worldwide Product Information Center nearest you: <http://www-k.ext.ti.com/sc/technical-support/product-information-centers.htm>.

## C.2 108-Ball BGA Package

### C.2.1 Package Dimensions

Figure C-4. Stellaris LM3S9B90 108-Ball BGA Package Dimensions

**Note:** The following notes apply to the package drawing.

1. ALL DIMENSIONS ARE IN MILLIMETERS.
2. 'e' REPRESENTS THE BASIC SOLDER BALL GRID PITCH.
3. 'M' REPRESENTS THE BASIC SOLDER BALL MATRIX SIZE.  
AND SYMBOL 'N' IS THE NUMBER OF BALLS AFTER DEPOPULATING.
4. 'b' IS MEASURABLE AT THE MAXIMUM SOLDER BALL DIAMETER AFTER REFLOW  
PARALLEL TO PRIMARY DATUM [C].
5. DIMENSION 'ccc' IS MEASURED PARALLEL TO PRIMARY DATUM [C].
6. PRIMARY DATUM [C] AND SEATING PLANE ARE DEFINED BY THE SPHERICAL  
CROWNS OF THE SOLDER BALLS.
7. PACKAGE SURFACE SHALL BE MATTE FINISH CHARMILLES 24 TO 27.
8. SUBSTRATE MATERIAL BASE IS BT RESIN.
9. THE OVERALL PACKAGE THICKNESS "A" ALREADY CONSIDERS COLLAPSE BALLS
10. DIMENSIONING AND TOLERANCING PER ASME Y14.5M 1994.
11. EXCEPT DIMENSION b.

## C.2.2 Tray Dimensions

Figure C-5. 108-Ball BGA Tray Dimensions

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
