

FEATURES

- Monitors Two Voltages Simultaneously
- Adjustable UV and OV Trip Values
- Guaranteed Threshold Accuracy: $\pm 1.5\%$
- Input Glitch Rejection
- Adjustable Reset Timeout with Disable
- 55 μ A Quiescent Current
- Open-Drain $\overline{\text{OV}}$ and $\overline{\text{UV}}$ Outputs
- Guaranteed $\overline{\text{OV}}$ and $\overline{\text{UV}}$ for $V_{CC} \geq 1\text{V}$
- Available in 10-Lead MSOP and (3mm \times 3mm) DFN Packages

APPLICATIONS

- Desktop and Notebook Computers
- Network Servers
- Core, I/O Voltage Monitors

DESCRIPTION

The LTC[®]2913 is a dual input voltage monitor intended for multiple voltages in a variety of applications. Dual inputs for each voltage allow monitoring two separate undervoltage (UV) conditions and two separate overvoltage (OV) conditions. All monitors share a common undervoltage output and a common overvoltage output. The LTC2913-1 has latching capability for the overvoltage output. The LTC2913-2 has functionality to disable both the overvoltage and undervoltage outputs.

Glitch filtering ensures reliable reset operation without false or noisy triggering.

The LTC2913 provides a precise, versatile, space-conscious, micropower solution for voltage monitoring.

LT, LT, LTC and LTM are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All currents into pins are positive; all voltages are referenced to GND unless otherwise noted.

Note 3: V_{CC} maximum pin voltage is limited by input current. Since the V_{CC} pin has an internal 6.5V shunt regulator, a low impedance supply that exceeds 6V may exceed the rated terminal current. Operation from higher voltage supplies requires a series dropping resistor. See Applications Information.

PIN FUNCTIONS

DIS (Pin 8, LTC2913-2): Output Disable Input. Disables the $\overline{\text{OV}}$ and $\overline{\text{UV}}$ output pins. When DIS is pulled high, the $\overline{\text{OV}}$ and $\overline{\text{UV}}$ pins are not asserted except during a UVLO condition. DIS has a weak ($2\mu\text{A}$) internal pull-down to GND. Leave DIS open if unused.

Exposed Pad (Pin 11, DFN Package): Exposed Pad may be left open or connected to device ground.

GND (Pin 5): Device Ground.

$\overline{\text{LATCH}}$ (Pin 8, LTC2913-1): $\overline{\text{OV}}$ Latch Clear/Bypass Input. When pin is pulled low, $\overline{\text{OV}}$ is latched when asserted. When pulled high, $\overline{\text{OV}}$ latch is cleared. While held high, $\overline{\text{OV}}$ has the same delay and output characteristics as $\overline{\text{UV}}$.

$\overline{\text{OV}}$ (Pin 6): Overvoltage Logic Output. Asserts low when either VL input voltage is above threshold. Latched low (LTC2913-1). Held low for programmed delay time after both VL inputs are valid (LTC2913-2). $\overline{\text{OV}}$ has a weak pull-up to V_{CC} and may be pulled above V_{CC} using an external pull-up. Leave $\overline{\text{OV}}$ open if unused.

PIN FUNCTIONS

TMR (Pin 9): Reset Delay Timer. Attach an external capacitor (C_{TMR}) of at least 10pF to GND to set a reset delay time of 9ms/nF. A 1nF capacitor will generate an 8.5ms reset delay time. Tie TMR to V_{CC} to bypass timer.

UV (Pin 7): Undervoltage Logic Output. Asserts low when either VH input voltage is below threshold. Held low for a programmed delay time after both VH inputs are valid. UV has a weak pull-up to V_{CC} and may be pulled above V_{CC} using an external pull-up. Leave UV open if unused.

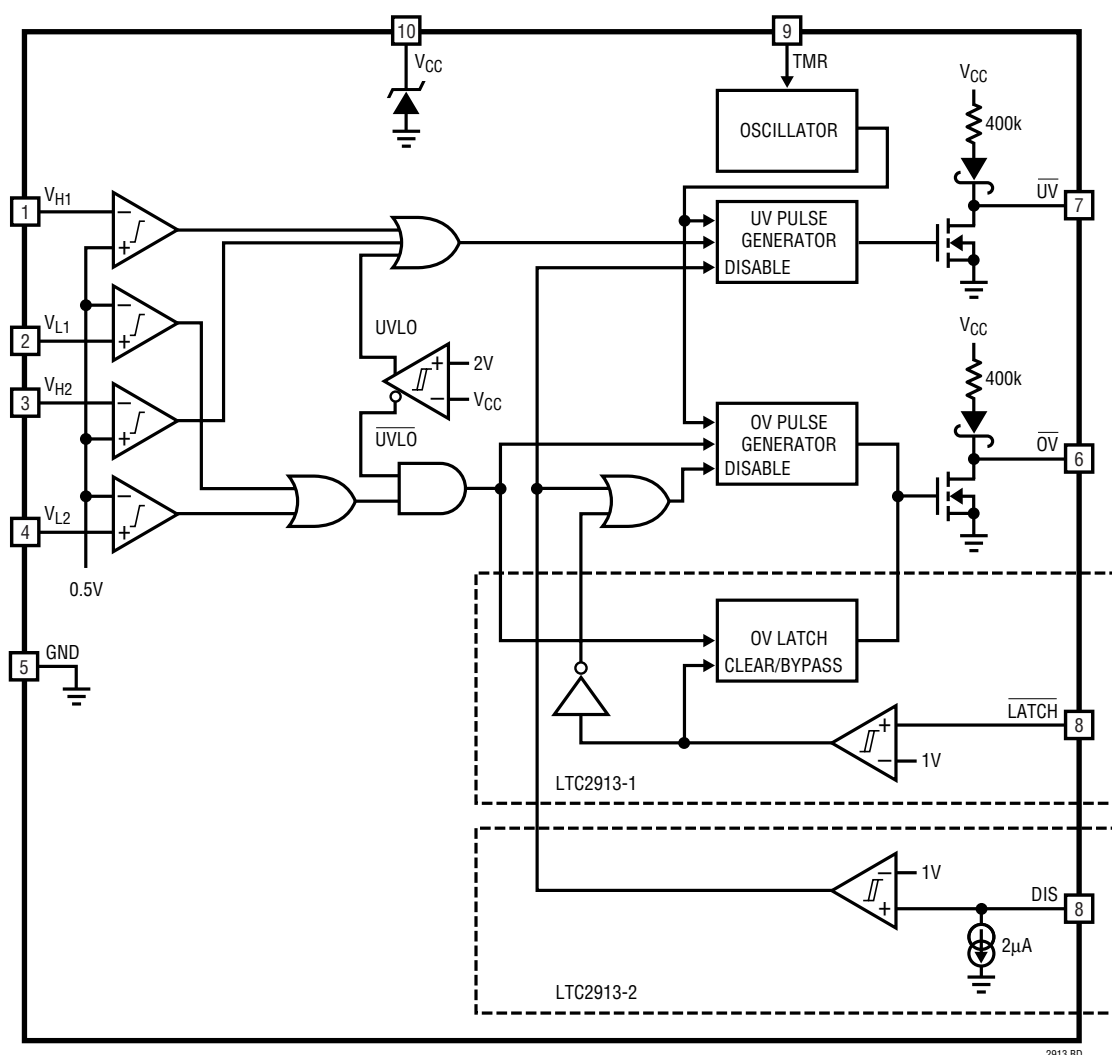

V_{CC} (Pin 10): Supply Voltage. Bypass this pin to GND with a 0.1 μ F (or greater) capacitor. Operates as a direct supply

input for voltages up to 6V. Operates as a shunt regulator for supply voltages greater than 6V and must have a resistance between the pin and the supply to limit input current to no greater than 10mA. When used without a current-limiting resistance, V_{CC} voltage must not exceed 6V.

VH1/VH2 (Pin 1/Pin 3): Voltage High Inputs 1 and 2. When the voltage on this pin is below 0.5V, an undervoltage condition is triggered. Tie pin to V_{CC} if unused.

VL1/VL2 (Pin 2/Pin 4): Voltage Low Inputs 1 and 2. When the voltage on this pin is above 0.5V, an overvoltage condition is triggered. Tie pin to GND if unused.

APPLICATIONS INFORMATION

Voltage Monitoring

The LTC2913 is a low power dual voltage monitoring circuit with two undervoltage and two overvoltage inputs. A timeout period that holds \overline{OV} and \overline{UV} asserted after all faults have cleared is adjustable using an external capacitor and is externally disabled.

Each voltage monitor has two inputs (V_{Hn} and V_{Ln}) for detecting undervoltage and overvoltage conditions. When configured to monitor a positive voltage V_n using the 3-resistor circuit configuration shown in Figure 1, V_{Hn} is connected to the high side tap of the resistive divider and V_{Ln} is connected to the low side tap of the resistive divider.

3-Step Design Procedure

The following 3-step design procedure determines appropriate resistances to obtain the desired UV and OV trip points for the voltage monitor circuit in Figure 1.

For supply monitoring, V_n is the desired nominal operating voltage, I_n is the desired nominal current through the resistive divider, V_{OV} is the desired overvoltage trip point and V_{UV} is the desired undervoltage trip point.

1. Choose R_A to obtain the desired OV trip point

R_A is chosen to set the desired trip point for the overvoltage monitor.

$$R_A = \left| \frac{0.5V}{I_n} \cdot \frac{V_n}{V_{OV}} \right| \quad (1)$$

Figure 1. 3-Resistor Positive UV/OV Monitoring Configuration

2. Choose R_B to obtain the desired UV trip point

Once R_A is known, R_B is chosen to set the desired trip point for the undervoltage monitor.

$$R_B = \left| \frac{0.5V}{I_n} \cdot \frac{V_n}{V_{UV}} \right| - R_A \quad (2)$$

3. Choose R_C to complete the design

Once, R_A and R_B are known, R_C is determined by:

$$R_C = \left| \frac{V_n}{I_n} \right| - R_A - R_B \quad (3)$$

If any of the variables V_n , I_n , V_{UV} or V_{OV} change, then each step must be recalculated.

Voltage Monitor Example

A typical voltage monitor application is shown in Figure 2. The monitored voltage is a $5V \pm 10\%$ supply. Nominal current in the resistive divider is $10\mu A$.

1. Find R_A to set the OV trip point of the monitor.

$$R_A = \left| \frac{0.5V}{10\mu A} \cdot \frac{5V}{5.5V} \right| \approx 45.3k$$

2. Find R_B to set the UV trip point of the monitor.

$$R_B = \left| \frac{0.5V}{10\mu A} \cdot \frac{5V}{4.5V} \right| - 45.3k \approx 10.2k$$

3. Determine R_C to complete the design.

$$R_C = \left| \frac{5V}{10\mu A} \right| - 45.3k - 10.2k \approx 442k$$

Figure 2. Typical Supply Monitor

APPLICATIONS INFORMATION

Power-Up/Power-Down

As soon as V_{CC} reaches 1V during power-up, the \overline{UV} output asserts low and the \overline{OV} output weakly pulls to V_{CC} .

The LTC2913 is guaranteed to assert \overline{UV} low and \overline{OV} high under conditions of low V_{CC} , down to $V_{CC} = 1V$. Above $V_{CC} = 2V$ (2.1V maximum), the V_H and V_L inputs take control.

Once both V_H inputs and V_{CC} are valid, an internal timer is started. After an adjustable delay time, \overline{UV} weakly pulls high.

Threshold Accuracy

Reset threshold accuracy is important in a supply-sensitive system. Ideally, such a system resets only if supply voltages fall outside the exact thresholds for a specified margin. All LTC2913 inputs have a relative threshold accuracy of $\pm 1.5\%$ over the full operating temperature range.

For example, when the LTC2913 is programmed to monitor a 5V input with a 10% tolerance, the desired UV trip point is 4.5V. Because of the $\pm 1.5\%$ relative accuracy of the LTC2913, the UV trip point is between 4.433V and 4.567V which is $4.5V \pm 1.5\%$.

Likewise, the accuracy of the resistances chosen for R_A , R_B and R_C can affect the UV and OV trip points as well. Using the example just given, if the resistances used to set the UV trip point have 1% accuracy, the UV trip range is between 4.354V and 4.650V. This is illustrated in the following calculations.

The UV trip point is given as:

$$V_{UV} = 0.5V \left(1 + \frac{R_C}{R_A + R_B} \right)$$

The two extreme conditions, with a relative accuracy of 1.5% and resistance accuracy of 1%, result in:

$$V_{UV(MIN)} = 0.5V \cdot 0.985 \cdot \left(1 + \frac{R_C \cdot 0.99}{(R_A + R_B) \cdot 1.01} \right)$$

and

$$V_{UV(MAX)} = 0.5V \cdot 1.015 \cdot \left(1 + \frac{R_C \cdot 1.01}{(R_A + R_B) \cdot 0.99} \right)$$

For a desired trip point of 4.5V, $\frac{R_C}{R_A + R_B} = 8$

Therefore,

$$V_{UV(MIN)} = 0.5V \cdot 0.985 \cdot \left(1 + 8 \frac{0.99}{1.01} \right) = 4.354V$$

and

$$V_{UV(MAX)} = 0.5V \cdot 1.015 \cdot \left(1 + 8 \frac{1.01}{0.99} \right) = 4.650V$$

Glitch Immunity

In any supervisory application, noise riding on the monitored DC voltage causes spurious resets. To solve this problem without adding hysteresis, which causes a new error term in the trip voltage, the LTC2913 lowpass filters the output of the first stage comparator at each input. This filter integrates the output of the comparator before asserting the UV or OV logic. A transient at the input of the comparator of sufficient magnitude and duration triggers the output logic. The Typical Performance Characteristics show a graph of the Transient Duration vs. Comparator Overdrive.

APPLICATIONS INFORMATION

UV/OV Timing

The LTC2913 has an adjustable timeout period (t_{UOTO}) that holds \overline{OV} or \overline{UV} asserted after all faults have cleared. This assures a minimum reset pulse width allowing a settling time delay for the monitored voltage after it has entered the valid region of operation.

When any V_H input drops below its designed threshold, the \overline{UV} pin asserts low. When all inputs recover above their designed thresholds, the UV output timer starts. If all inputs remain above their designed thresholds when the timer finishes, the \overline{UV} pin weakly pulls high. However, if any input falls below its designed threshold during this timeout period, the timer resets and restarts when all inputs are above the designed thresholds. The \overline{OV} output behaves as the \overline{UV} output when \overline{LATCH} is high (LTC2913-1).

Selecting the UV/OV Timing Capacitor

The UV and OV timeout period (t_{UOTO}) for the LTC2913 is adjustable to accommodate a variety of applications. Connecting a capacitor, C_{TMR} , between the TMR pin and ground sets the timeout period. The value of capacitor needed for a particular timeout period is:

$$C_{TMR} = t_{UOTO} \cdot 115 \cdot 10^{-9} \text{ [F/s]}$$

The Reset Timeout Period vs Capacitance graph found in the Typical Performance Characteristics shows the desired delay time as a function of the value of the timer capacitor that must be used. The TMR pin must have a minimum 10pF load or be tied to V_{CC} . For long timeout periods, the only limitation is the availability of a large value capacitor with low leakage. Capacitor leakage current must not exceed the minimum TMR charging current of 1.3 μ A. Tying the TMR pin to V_{CC} will bypass the timeout period.

Undervoltage Lockout

When V_{CC} falls below 2V, the LTC2913 asserts an undervoltage lockout (UVLO) condition. During UVLO, \overline{UV} is asserted and pulled low while \overline{OV} is cleared and blocked from asserting. When V_{CC} rises above 2V, \overline{UV} follows the same timing procedure as an undervoltage condition on any input.

Shunt Regulator

The LTC2913 has an internal shunt regulator. The V_{CC} pin operates as a direct supply input for voltages up to 6V. Under this condition, the quiescent current of the device remains below a maximum of 80 μ A. For V_{CC} voltages higher than 6V, the device operates as a shunt regulator and must have a resistance R_Z between the supply and the V_{CC} pin to limit the current to no greater than 10mA.

When choosing this resistance value, select an appropriate location on the I-V curve shown in the Typical Performance Characteristics to accommodate any variations in V_{CC} due to changes in current through R_Z .

\overline{UV} and \overline{OV} Output Characteristics

The DC characteristics of the \overline{UV} and \overline{OV} pull-down strength are shown in the Typical Performance Characteristics. Each pin has a weak internal pull-up to V_{CC} and a strong pull-down to ground. This arrangement allows these pins to have open-drain behavior while possessing several other beneficial characteristics. The weak pull-up eliminates the need for an external pull-up resistor when the rise time on the pin is not critical. On the other hand, the open-drain configuration allows for wired-OR connections, and is useful when more than one signal needs to pull down on the output. V_{CC} of 1V guarantees a maximum $V_{OL} = 0.15V$ at \overline{UV} .

At $V_{CC} = 1V$, the weak pull-up current on \overline{OV} is barely turned on. Therefore, an external pull-up resistor of no more than 100k is recommended on the \overline{OV} pin if the state and pull-up strength of the \overline{OV} pin is crucial at very low V_{CC} .

Note however, by adding an external pull-up resistor, the pull-up strength on the \overline{OV} pin is increased. Therefore, if it is connected in a wired-OR connection, the pull-down strength of any single device must accommodate this additional pull-up strength.

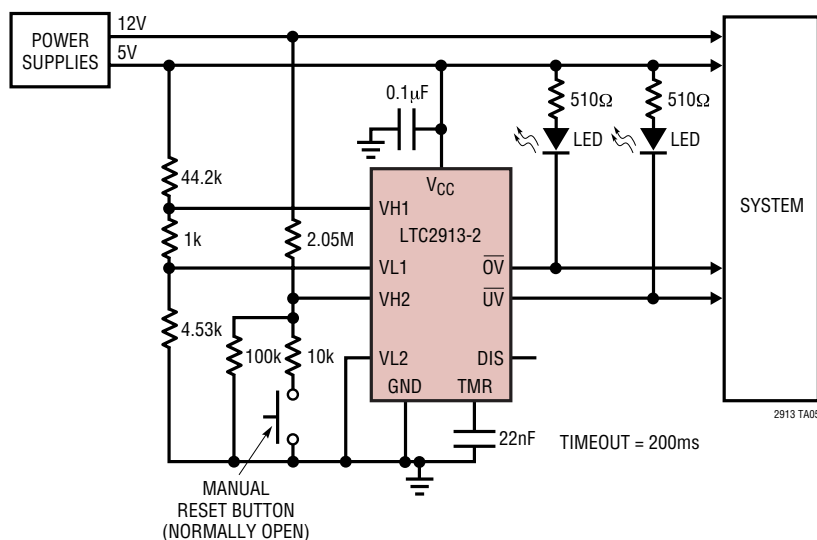

Output Rise and Fall Time Estimation

The \overline{UV} and \overline{OV} outputs have strong pull-down capability. The following formula estimates the output fall time (90% to 10%) for a particular external load capacitance (C_{LOAD}):

$$t_{FALL} \approx 2.2 \cdot R_{PD} \cdot C_{LOAD}$$
