

ISL1539A

Dual Port VDSL2 Line Driver

FN6916

Rev 0.00

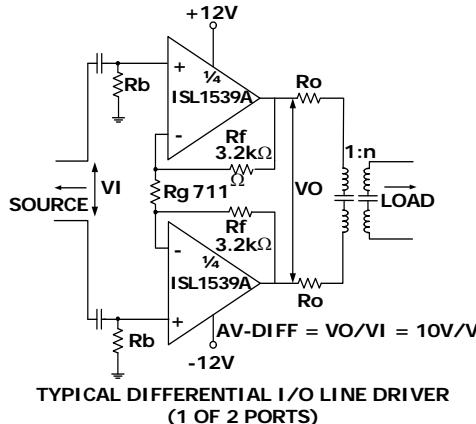

September 23, 2009

The ISL1539A provides 4 internal wideband op amps intended to be used as two pairs of differential line drivers. The ISL1539A's high bandwidth, 240MHz, and ultra low distortion, -89dBc @ 1MHz, 2V_{P-P}, support the demanding MTPR requirements of emerging VDSL2 line driver designs. Less demanding requirements can be met at very low quiescent powers using the supply current adjustment features.

Each of the 4 internal op amps is a wideband current feedback amplifier offering very high slew rate intrinsic to that design using low quiescent current levels. Each of the two pair of amplifiers (ports) can also be power optimized to the application using two external quiescent control logic pins. Full power is nominally 27.2mA/port with options of medium power cutback to 23mA/port, a low power condition at 13.5mA/port, and an off state at <0.5mA/port. Added quiescent power flexibility is provided through an external I_{ADJ} pin. Grounding the pin gives the nominal currents listed above while inserting a resistor from this pin to ground can be used to scale each of the settings downward.

High power push/pull line driver applications as illustrated in the example below are best supported using a low headroom, high output current device. On $\pm 12V$ supplies, the ISL1539A offers a 1.1V headroom with >360mA peak output current. Driving differentially this gives >41.8V_{P-P} swing to as low as 58Ω differential load. High SFDR operation is also supported for supplies as low as $\pm 7.5V$. Intended to be used as differential pairs, this two port device includes special circuitry to minimize common mode loop peaking while also reducing the common mode output noise spectrum. That circuitry links the two sides of each port, precluding their application as individual amplifiers.

Typical Application

Features

- 360mA Output Drive Capability
- 41.8V_{P-P} Differential Output Drive into 100Ω
- -89dBc THD @ 1MHz 2V_{P-P}
- -65dBc MTPR (VDSL 8b Profile)
- High Slew Rate of 3000V/μs Differential
- Bandwidth (240MHz @ $A_{V-DIFF} = 10$)
- Supply Current Control Pins
- Port Separation
 - 78dB @ 500kHz
 - 70dB @ 1MHz
 - 60dB @ 4MHz
- Pb-Free (RoHS Compliant)

Applications* (see page 21)

- 8MHz and 17MHz VDSL2 Profiles
- ADSL2+

NOTES:

1. Please refer to [TB347](#) for details on reel specifications.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), please see device information page for [ISL1539A](#). For more information on MSL please see techbrief [TB363](#).

Operating Conditions

Ambient Temperature Range	-40°C to +85°C
Junction Temperature Range	-40°C to +150°C

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

NOTES:

4. θ_{JA} is measured with the component mounted on a high effective thermal conductivity test board in free air. QFN and HTSSOP exposed pad soldered to PCB per JESD51-5. See Tech Brief TB379 for details.
5. For θ_{JC} , the "case temp" location is the center of the exposed metal pad on the package underside.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typ values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore: $T_J = T_C = T_A$

Electrical Specifications $V_S = \pm 12\text{V}$, $R_L = 100\Omega$ differential, $I_{ADJ} = C_0 = C_1 = 0\text{V}$, $A_V = 10\text{V/V}$, $R_F = 3.2\text{k}\Omega$, $T_A = +25^\circ\text{C}$. Amplifier pairs tested separately unless otherwise indicated.

Applications Information

Applying Wideband Current Feedback Op Amps as Differential Drivers

A current feedback amplifier (CFA) like the ISL1539A is particularly suited to the requirements of high output power, high full power bandwidth, differential drivers. This topology offers a very high slew rate on low quiescent power and the ability to hold relatively constant AC characteristics over a wide range of gains. The AC characteristics are principally set by the feedback resistor value in simple differential gain circuits as shown in Figure 44.

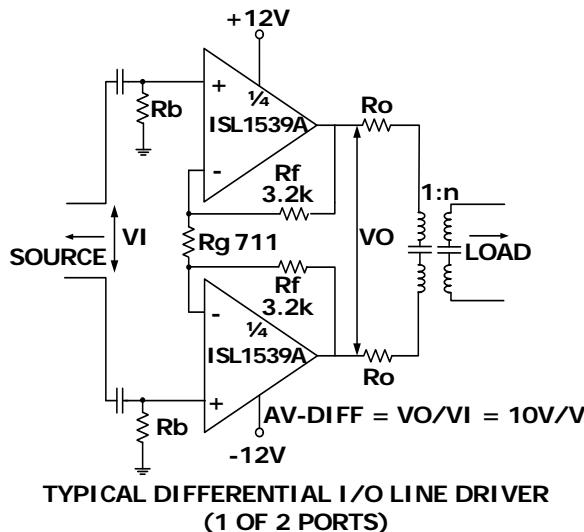

FIGURE 44. PASSIVE TERMINATION CIRCUIT

In this differential gain of 10 V/V circuit, the 3.2k feedback resistors are setting the bandwidth while the 711 gain resistor controls the gain. The V_o/V_i gain for this circuit is set by Equation 1:

$$\frac{V_o}{V_i} = 1 + 2 \frac{R_f}{R_g} = 1 + 2 \frac{3.2k\Omega}{711\Omega} = 10 \quad (\text{EQ. 1})$$

The effect of increasing or decreasing the feedback resistor value is shown in Figures 19, 24 and 29 (at the 3 power settings). Increasing R_f will tend to roll off the response while decreasing it will peak the frequency response up extending the bandwidth. R_g was adjusted in each of these plots to hold a constant gain of 10 (or 20dB). This shows the flexibility offered by the CFA topology - the frequency response can be controlled with the value of the feedback resistor with the R_g resistor then setting the desired gain.

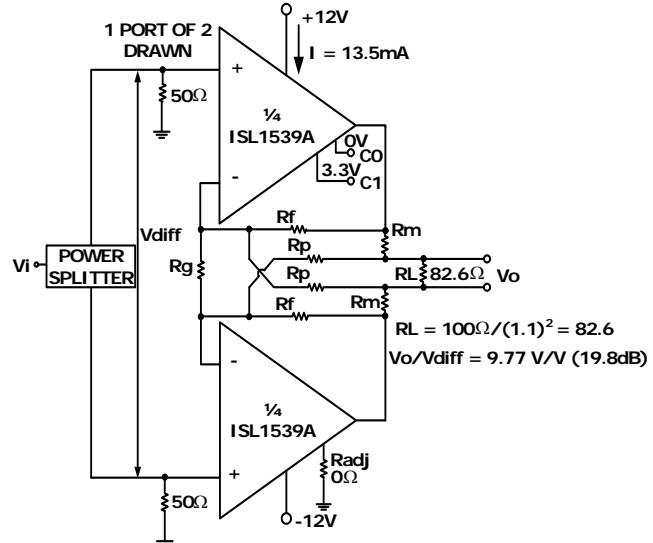

The ISL1539A provides 4 very power efficient, high output current, CFA's. These are intended to be connected as two pairs of differential drivers. The pinout diagrams of page two show that Channels A and B are intended to operate as a pair while Channels C and D comprise the other pair. Power control is also provided through two pairs of control pins which separately set the

power for Channels A and B together and then the other pair controls Channels C and D together.

Very low output distortion at low power can be provided by the differential configuration. The high slew rate intrinsic to the CFA topology also contributes to the exceptional performance shown in Figures 22, 27 and 32. These swept frequency distortion plots show extremely low distortion at 200kHz holding to very low levels up through 20MHz. At the lowest operating power (Figure 32, which is at low power, or 6.75mA per amplifier or 13.5mA/port) we still see $< -70\text{dBc}$ through 5MHz for a 5V_{p-p} differential output swing.

Advanced Configurations - Active Termination

Where the best power efficiency is required in a full duplex DSL line interface application, it is common to apply the circuit shown below to reduce the power loss in the matching element while retaining a higher impedance for the upstream signal coming into this output stage. This circuit acts to provide a higher apparent output impedance (through its cross-coupled positive feedback through the R_p resistors) while physically taking a smaller IR drop through the R_m resistors for the output signal.

This circuit is showing one of two ports configured in an active termination circuit used for some of the specification and characterization tests. This is showing the device operating in the low power mode, but data has been shown at the other power settings as well.

The 82.6Ω differential load is intended to emulate a 100Ω line load reflected through a 1:1.1 turns ratio transformer ($100\Omega/(1.1^2) = 82.6\Omega$ load). The gain and output impedance for this circuit can be described by the following equations.

The ideal transfer function is set by the open circuit gain ($RL = \infty$) and an equivalent output impedance Z_0 .

$$\frac{V_o}{V_i} = A_{oc} \frac{R_L}{R_L + Z_o} \quad (\text{EQ. 2})$$

The goal of the positive feedback resistor, R_p , is to provide some "gain" in the apparent output impedance over just the $2 \cdot R_M$. It also will act to increase the A_{OC} over the simple differential gain equation if a synthesis factor (SF) is defined as shown in Equation 3:

$$SF = \frac{1}{1 - \frac{R_f - R_m}{R_p}} \quad (\text{EQ. 3})$$

We can see this "gain" is achieved by letting R_p be $> R_f$. The closer R_p is to $R_f - R_M$, the more "gain" is achieved but at the risk of instability. With this SF defined as shown above, the exact A_{OC} and Z_O will be as shown in Equations 4 and 5:

$$A_{oc} = SF \left(1 + 2 \frac{R_f}{R_g} + \frac{R_f - R_m}{R_p} \right) \quad (\text{EQ. 4})$$

$$Z_O = SF(2R_m) \quad (\text{EQ. 5})$$

For test purposes, the circuit shown in Figure 45 was configured to achieve the following results.

$A_{OC} = 2.19$

$A_{OC} = 17.7V/V$

$Z_O = 66\Omega$

Putting these together into the gain to an 82.6Ω load gives the following test condition as shown by Equation 6.

$$\frac{V_o}{V_i} = A_{oc} \frac{R_L}{R_L + Z_o} = 17.7 \frac{82.6\Omega}{82.6\Omega + 66\Omega} = 9.84 \left(\frac{V}{V} \right) \quad (\text{EQ. 6})$$

The advantage offered by this technique is that for whatever swing we desire at the load, there is less rise through the physical output matching resistor than if we simply inserted two 33Ω R_M resistors to achieve the 66Ω output impedance achieved in this test circuit. Whatever load current is required in R_L will rise to the output pins through $2 \cdot R_M$. The rise from the load swing to the output pin swing is given by Equation 7:

$$\frac{R_L + 2R_m}{R_L} \quad (\text{EQ. 7})$$

This was only 1.36 for the test circuit shown above. In differential circuits the $\pm V_p$ at the output pins produces a $4V_p$ for the differential peak-to-peak voltage. Hence a $\pm 10V$ swing at each output in the above circuit will

produce a $40V_{p-p}$ differential swing which will drop to the load divided by 1.36 - or a $29.41V_{p-p}$ differential swing.

Distortion and MTPR

The ISL1539A is intended to provide very low distortion levels under the demanding conditions required by the discrete multi-tone (DMT) characteristic of modern DSL modulations. The standard test for linearity is the Multi-Tone Power Ratio (MTPR) test where a specified standard is loaded up with discrete carriers over the specified frequencies in such a way as to produce the maximum rated line power and Peak to Average Ratio (PAR) with some tones missing. The measure of linearity is the separation from the active tones vs. a missing tone. To the extent that the amplifier is slightly non-linear, it will fold a small amount of power into the missing tones through intermodulation products for the active tones. Figure 17 shows the circuit operating at the low power setting used to test ADSL2+ frequency plan and power. For this test the carriers are spaced at 5kHz.

This -60dBc MTPR is exceptional for the very low 13.5mA total quiescent current used in this configuration. Operating at reduced power targets on the line will improve MTPR as will operating the amplifiers at higher quiescent current.

The characteristic curves show the exceptional single tone performance available using the ISL1539A. At the highest quiescent power, operating at a simple differential gain of $10V/V$, Figure 22 shows the $5V_{p-p}$ distortion plot.

Figure 22 shows a better than -80dBc through 8MHz for the 2nd and 3rd harmonics. The rapid rise in the spurious above 10MHz is coming from the onset of fine scale slew limiting effects. By 20MHz, the output signal is requiring a differential slew rate of $300V/\mu\text{s}$ - a significant portion of the available $3000V/\mu\text{s}$ slew rate available at full power.

Power Control Function

Figure 46 shows a simplified schematic for the power control features included in the ISL1539A. Each of the 4 differential pairs shown in the drawing are used to steer control currents (I_{BIAS} terms) into additional current mirrors (not shown) that control the quiescent bias current for each of the two ports. This bias control shares the I_{ADJ} pin. When I_{ADJ} is grounded, the typical supply current levels shown in the "Electrical Specifications" tables on page 5 are produced. Inserting an external resistor to ground in the I_{ADJ} pin will scale the quiescent currents down, as shown in Figure 38.

It is also possible to scale the I_{ADJ} currents up by tying the I_{ADJ} pin through a resistor to a negative supply. As long as the resulting voltage divider between this external negative voltage and the internal $+0.4V$ on the other side of the 500Ω resistor stays above the maximum rated negative voltage on the I_{ADJ} pin ($-1V$). For instance, to double the typical quiescent current levels, the current in the I_{ADJ} pin must be doubled from its nominal $800\mu\text{A}$ level. Using a $-5V$ supply through an

external $2.88\text{k}\Omega$ resistor will double the current while leaving the I_{ADJ} pin voltage at approximately -0.4V , which is well within rated minimum. This approach should be used with great caution as very high internal power dissipations can easily be produced. However, it can be a useful approach to extend operation, particularly when operating on lower total supply voltages than the rated typical of $\pm 12\text{V}$.

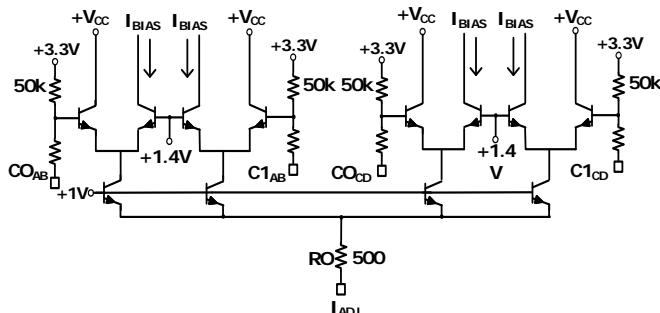

FIGURE 46. BIAS CONTROL CIRCUIT

The current in RO divides in 1/4 levels to form the bias current for the 4 pairs of differential switches. Each pair of switches controls the quiescent current for one port. For instance, CO_{AB} and $C1_{AB}$ control the quiescent current for the port constructed from amplifiers A and B. If both control lines are unconnected externally, the internal $50\text{k}\Omega$ pull-up will switch the differential pairs to divert the $100\mu\text{A}$ tail currents into the supply turning off the amplifiers. Taking both control pins low will pass both I_{BIAS} lines on into scaling current sources. With I_{REF} grounded, this will give the typical 27.2mA total quiescent current for a port shown in the "Electrical Specification" tables on page 5. Taking C_0 high ($>2\text{V}$) while leaving C_1 low ($<0.8\text{V}$) will reduce the current into a port to a typical 23mA . Taking C_1 high, while leaving C_0 low will reduce the current in a port to a typical 13.5mA supply current. Table 2 summarizes the operation modes for ISL1539A for each port.

TABLE 2. POWER MODES OF THE ISL1539A

C_1	C_0	OPERATION
0	0	I_S Full Power Mode
0	1	I_S Medium Power Mode
1	0	I_S Low Power Mode
1	1	Power-Down

Performance Considerations

Driving Capacitive Loads

All closed loop op amps are susceptible to reduced phase margin when driving capacitive loads. This shows up as peaking in the frequency response that can, in extreme situations, lead to oscillations. The ISL1539A is designed to operate successfully with small capacitive loads such as layout parasitics. As the parasitic capacitance increases, it is best consider a small resistor in series

with the output to isolate the phase margin effects of the capacitor. Figure 20 on page 10 shows the effect of capacitive load on the differential gain of 10 circuit. With 15pF on each output, we see about 5dB peaking. This will increase quickly at higher C_{loads} . If this degree of peaking is unacceptable, a small series resistor can be used to improve the flatness as shown in Figure 21.

Output DC Error Model

Often, non-inverting bias current (i_{bn}), inverting bias current (i_{bi}), and input offset voltage (V_{io}) are quite low for typical op amps.

V_{io} , i_{bn} , i_{bi} can be mapped to output offset both common and differential mode. Consider the circuit in Figure 47.

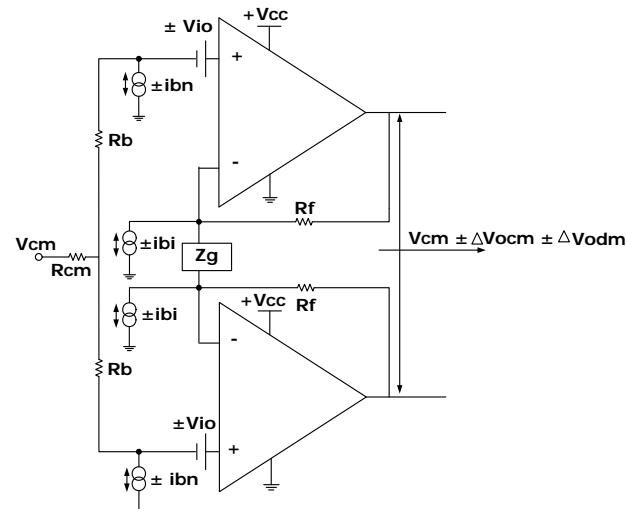

FIGURE 47. DC ERROR MODEL

The output common mode offset voltage (V_{o-cm}) is derived from the input common mode voltage (V_{i-cm}), as expressed in Equations 8 and 9:

$$V_{icm} = \pm 2 \times i_{bn} \times R_{cm} \pm i_{bn} \times R_b \pm V_{io} \quad (\text{EQ. 8})$$

$$V_{ocm} = \pm V_{icm} \pm R_f \times i_{bi} \quad (\text{EQ. 9})$$

The output differential mode offset voltage (V_{o-dm}) is derived from the input differential mode voltage (V_{i-dm}), as expressed in Equations 10 and 11:

$$V_{idm} = \pm \Delta i_{bn} \times R_b \pm \Delta V_{io} \quad (\text{EQ. 10})$$

$$V_{odm} = \pm V_{idm} \times \left(1 + \frac{2R_f}{R_g}\right) \pm \Delta i_{bi} \times R_f \quad (\text{EQ. 11})$$

Example:

Referring to the "Electrical Specification" tables on page 6:

$$i_{bn} = 8\mu\text{A}, \Delta i_{bn} = 2\mu\text{A}$$

$$i_{bi} = 75\mu\text{A}, \Delta i_{bi} = 35\mu\text{A}$$

$$V_{io} = 8\text{mV}, \Delta V_{io} = 2\text{mV}$$

Assuming $R_f = 3k\Omega$, $R_g = 333\Omega$, $R_b = 7.5k\Omega$, $R_{cm} = 5k\Omega$, the total output offset voltage derived is expressed in Equation 12:

$$V_{cm} = V_{ocm} + 0.5 \times V_{odm} = 434\text{mV} \quad (\text{EQ. 12})$$

Given the worst case DC errors, 434mV of DC shift will be at the output reducing the available output swing slightly. Actual operation should never see this much shift as the error terms are not completely independent.

Output Headroom Model

Driving high voltages into heavy loads will require a careful consideration of the available output swing vs. load. Figure 48 shows a useful model for predicting the available output swing. If the output is modeled as ideal NPN and PNP transistors, the output swing limits can be described as no load headrooms (V_p and V_N) and an equivalent impedance to the supplies (R_p and R_N)

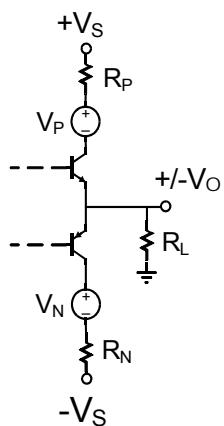

FIGURE 48. HEADROOM MODEL

The no load headrooms can be found in the "Electrical Specifications" table on page 5 as $12\text{V} - 10.9\text{V} = 1.1\text{V}$ and they are equal to each supply.

The equivalent impedances for this model can be extracted from the reduced swings shown in the specification table for the heavier loads. Looking at the typical 60Ω load swings, we see a $+9.8\text{V}$ and -9.7V swing. Solving for the two resistors in the Headroom model shown in Figure 48 gives:

$$R_p = 6.7\Omega \text{ and } R_N = 7.4\Omega$$

For the differential configuration, Figure 49 shows the Headroom model that can be used to predict the maximum available swing for a given supply voltage and load resistor, R_L .

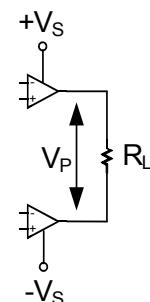

FIGURE 49. HEADROOM MODEL

For equal bipolar supplies, the available peak output swing will be given by Equation 13:

$$V_p = \frac{2(V_s - V_p - V_n)}{1 + \frac{R_p + R_n}{R_L}} \quad (\text{EQ. 13})$$

For example, to worst case the typical gain of 10 design using $\pm 12\text{V}$ supplies with $\pm 5\%$ supply tolerance and a minimum expected load of 90Ω , a maximum V_p can be calculated as shown in Equation 14:

$$V_p = \frac{2(V_s - V_p - V_n)}{1 + \frac{R_p + R_n}{R_L}} = \frac{2(11.4 - 2.2)}{1 + \frac{6.7\Omega + 7.4\Omega}{90\Omega}} = 15.9V_p \quad (\text{EQ. 14})$$

The minimum V_{p-p} would be twice this, or $31.8V_{p-p}$. While this extreme condition would normally not be encountered, it does show the importance of knowing your minimum expected load for high output swing conditions.

Output Noise Model

The full differential output noise model for the ISL1539A should include the 3 input noise terms for each device as well as the noise contributions due to the external resistors.

This necessarily becomes an involved model due to the number of terms, but if the terms that are the same on each side of the differential circuit can be assumed to be equal, it will simplify considerably. The noise model shown in Figure 50 includes all of the op amp terms and resistor terms. This model is directed at calculating the differential output spot noise for different values of the resistors in the simple differential gain circuit. It is assuming each amplifier term is independent and uncorrelated to the other terms.

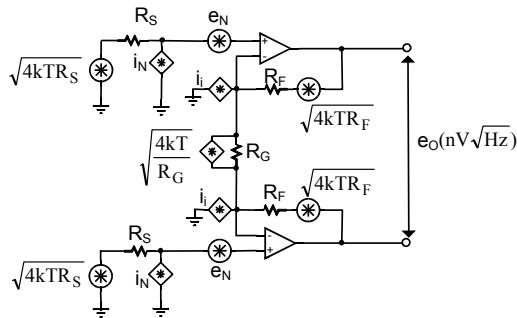

FIGURE 50. OUTPUT NOISE MODEL

In Figure 50, the circle sources are noise voltages while the diamonds are noise currents and $4kT$ is $1.6E - 20J$.

If the op amp terms are assumed to be equal for the two sides of the circuit and two R_F and R_S resistors are also equal, and the differential gain is defined as

$A_d = 1 + 2R_F/R_G$, the differential output noise expression becomes Equation 15.

$$e_o = \sqrt{2(A_d^2)(e_n^2 + (i_n R_s)^2 + 4kTR_s) + 2(i_i R_f)^2 + 2A_d(4kTR_f)} \quad (\text{EQ. 15})$$

Putting in numbers for the gain of 10 characterization circuit (with $R_S = 50\Omega$) gives a differential output noise of $e_o = 69\text{nV}/\sqrt{\text{Hz}}$. Dividing this by the differential gain of 10 gives an input noise of $e_i = 6.9\text{nV}/\sqrt{\text{Hz}}$ which is only slightly more than the RMS sum of the two 4nV input voltage noise terms for the op amps themselves ($5.7\text{nV}/\sqrt{\text{Hz}}$).

Board Design Recommendations

The feedback resistors need to be placed as close as possible to the output and inverting input pins to minimize parasitic capacitance in the feedback loop. This includes the R_F and R_P resistors in the active termination configuration. Keep the gain resistor also very close to the inverting inputs for its port and minimize parasitic capacitances to ground or power planes as well.

Close placement of the supply decoupling capacitors will minimize parasitic inductance in the supply path. High frequency load currents are typically pulled through these capacitors so close placement of $0.01\mu\text{F}$ capacitors on each of the supply pins will improve dynamic performance. Higher valued capacitors, $6.8\mu\text{F}$ typically, can be placed further from the package as they are providing more of the low frequency decoupling.

The thermal pad for the ISL1539A should be connected to either ground or the $-V_S$ power plane. The choice of which plane depends on which one would have the more accessible thermal area.

While the ISL1539A is relatively robust in driving parasitic capacitive loads, it is always preferred to get into any series output resistor needed in the design as physically close as possible to the output pins. Then trace capacitance on the other side of that resistor will have a much smaller effect on loop phase margin.

Protection devices that are intended to steer large load transients away from the ISL1539A output stage and into the power supplies or ground should have a short trace from their supply connections into the nearest supply capacitor - or should include their own supply capacitors to provide a low impedance path under fast transient conditions.

Products

Intersil Corporation is a leader in the design and manufacture of high-performance analog semiconductors. The Company's products address some of the industry's fastest growing markets, such as, flat panel displays, cell phones, handheld products, and notebooks. Intersil's product families address power management and analog signal processing functions. Go to www.intersil.com/products for a complete list of Intersil product families.

*For a complete listing of Applications, Related Documentation and Related Parts, please see the respective device information page on intersil.com: [ISL1539A](#)
