## Phase-locked-loop with VCO

## 74HC/HCT4046A

### FEATURES

- Low power consumption
- Centre frequency of up to 17 MHz (typ.) at  $V_{CC} = 4.5\text{ V}$
- Choice of three phase comparators: EXCLUSIVE-OR; edge-triggered JK flip-flop; edge-triggered RS flip-flop
- Excellent VCO frequency linearity
- VCO-inhibit control for ON/OFF keying and for low standby power consumption
- Minimal frequency drift
- Operating power supply voltage range:  
VCO section 3.0 to 6.0 V  
digital section 2.0 to 6.0 V
- Zero voltage offset due to op-amp buffering
- Output capability: standard
- $I_{CC}$  category: MSI.

### GENERAL DESCRIPTION

The 74HC/HCT4046A are high-speed Si-gate CMOS devices and are pin compatible with the "4046" of the "4000B" series. They are specified in compliance with JEDEC standard no. 7A.

The 74HC/HCT4046A are phase-locked-loop circuits that comprise a linear voltage-controlled oscillator (VCO) and three different phase comparators (PC1, PC2 and PC3) with a common signal input amplifier and a common comparator input.

The signal input can be directly coupled to large voltage signals, or indirectly coupled (with a series capacitor) to small voltage signals. A self-bias input circuit keeps small voltage signals within the linear region of the input amplifiers. With a passive low-pass filter, the "4046A" forms a second-order loop PLL. The excellent VCO linearity is achieved by the use of linear op-amp techniques.

The VCO requires one external capacitor C1 (between C1<sub>A</sub> and C1<sub>B</sub>) and one external resistor R1 (between R<sub>1</sub> and GND) or two external resistors R1 and R2 (between R<sub>1</sub> and GND, and R<sub>2</sub> and GND). Resistor R1 and capacitor C1 determine the frequency range of the VCO. Resistor R2 enables the VCO to have a frequency offset if required.

The high input impedance of the VCO simplifies the design of low-pass filters by giving the designer a wide choice of resistor/capacitor ranges. In order not to load the low-pass filter, a demodulator output of the VCO input voltage is

provided at pin 10 (DEM<sub>OUT</sub>). In contrast to conventional techniques where the DEM<sub>OUT</sub> voltage is one threshold voltage lower than the VCO input voltage, here the DEM<sub>OUT</sub> voltage equals that of the VCO input. If DEM<sub>OUT</sub> is used, a load resistor (R<sub>S</sub>) should be connected from DEM<sub>OUT</sub> to GND; if unused, DEM<sub>OUT</sub> should be left open. The VCO output (VCO<sub>OUT</sub>) can be connected directly to the comparator input (COMP<sub>IN</sub>), or connected via a frequency-divider. The VCO output signal has a duty factor of 50% (maximum expected deviation 1%), if the VCO input is held at a constant DC level. A LOW level at the inhibit input (INH) enables the VCO and demodulator, while a HIGH level turns both off to minimize standby power consumption.

The only difference between the HC and HCT versions is the input level specification of the INH input. This input disables the VCO section. The sections of the comparator are identical, so that there is no difference in the SIG<sub>IN</sub> (pin 14) or COMP<sub>IN</sub> (pin 3) inputs between the HC and HCT versions.

### Phase comparators

The signal input (SIG<sub>IN</sub>) can be directly coupled to the self-biasing amplifier at pin 14, provided that the signal swing is between the standard HC family input logic levels. Capacitive coupling is required for signals with smaller swings.

#### Phase comparator 1 (PC1)

This is an EXCLUSIVE-OR network. The signal and comparator input frequencies ( $f_i$ ) must have a 50% duty factor to obtain the maximum locking range. The transfer characteristic of PC1, assuming ripple ( $f_r = 2f_i$ ) is

suppressed, is: 
$$V_{\text{DEMOUT}} = \frac{V_{CC}}{\pi} (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$$

where  $V_{\text{DEMOUT}}$  is the demodulator output at pin 10;  
 $V_{\text{DEMOUT}} = V_{\text{PC1OUT}}$  (via low-pass filter).

The phase comparator gain is: 
$$K_p = \frac{V_{CC}}{\pi} (V/r).$$

The average output voltage from PC1, fed to the VCO input via the low-pass filter and seen at the demodulator output at pin 10 ( $V_{\text{DEMOUT}}$ ), is the resultant of the phase differences of signals (SIG<sub>IN</sub>) and the comparator input (COMP<sub>IN</sub>) as shown in Fig.6. The average of  $V_{\text{DEMOUT}}$  is equal to  $\frac{1}{2}V_{CC}$  when there is no signal or noise at SIG<sub>IN</sub> and with this input the VCO oscillates at the centre frequency ( $f_o$ ). Typical waveforms for the PC1 loop locked at  $f_o$  are shown in Fig.7.

## Phase-locked-loop with VCO

## 74HC/HCT4046A

The frequency capture range ( $2f_c$ ) is defined as the frequency range of input signals on which the PLL will lock if it was initially out-of-lock. The frequency lock range ( $2f_L$ ) is defined as the frequency range of input signals on which the loop will stay locked if it was initially in lock. The capture range is smaller or equal to the lock range.

With PC1, the capture range depends on the low-pass filter characteristics and can be made as large as the lock range.

This configuration retains lock even with very noisy input signals. Typical behaviour of this type of phase comparator is that it can lock to input frequencies close to the harmonics of the VCO centre frequency.

### Phase comparator 2 (PC2)

This is a positive edge-triggered phase and frequency detector. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of  $SIG_{IN}$  and  $COMP_{IN}$  are not important. PC2 comprises two D-type flip-flops, control-gating and a 3-state output stage. The circuit functions as an up-down counter (Fig.5) where  $SIG_{IN}$  causes an up-count and  $COMP_{IN}$  a down-count. The transfer function of PC2, assuming ripple ( $f_r = f_i$ ) is suppressed,

$$\text{is: } V_{DEMOUT} = \frac{V_{CC}}{4\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

where  $V_{DEMOUT}$  is the demodulator output at pin 10;  
 $V_{DEMOUT} = V_{PC2OUT}$  (via low-pass filter).

$$\text{The phase comparator gain is: } K_p = \frac{V_{CC}}{4\pi} (V/r) .$$

$V_{DEMOUT}$  is the resultant of the initial phase differences of  $SIG_{IN}$  and  $COMP_{IN}$  as shown in Fig.8. Typical waveforms for the PC2 loop locked at  $f_o$  are shown in Fig.9.

When the frequencies of  $SIG_{IN}$  and  $COMP_{IN}$  are equal but the phase of  $SIG_{IN}$  leads that of  $COMP_{IN}$ , the p-type output driver at  $PC2_{OUT}$  is held "ON" for a time corresponding to the phase difference ( $\phi_{DEMOUT}$ ). When the phase of  $SIG_{IN}$  lags that of  $COMP_{IN}$ , the n-type driver is held "ON".

When the frequency of  $SIG_{IN}$  is higher than that of  $COMP_{IN}$ , the p-type output driver is held "ON" for most of the input signal cycle time, and for the remainder of the cycle both n and p- type drivers are "OFF" (3-state). If the  $SIG_{IN}$  frequency is lower than the  $COMP_{IN}$  frequency, then it is the n-type driver that is held "ON" for most of the cycle. Subsequently, the voltage at the capacitor (C2) of the low-pass filter connected to  $PC2_{OUT}$  varies until the signal

and comparator inputs are equal in both phase and frequency. At this stable point the voltage on C2 remains constant as the  $PC2$  output is in 3-state and the VCO input at pin 9 is a high impedance. Also in this condition, the signal at the phase comparator pulse output ( $PCP_{OUT}$ ) is a HIGH level and so can be used for indicating a locked condition.

Thus, for PC2, no phase difference exists between  $SIG_{IN}$  and  $COMP_{IN}$  over the full frequency range of the VCO. Moreover, the power dissipation due to the low-pass filter is reduced because both p and n-type drivers are "OFF" for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range and is independent of the low-pass filter. With no signal present at  $SIG_{IN}$  the VCO adjusts, via PC2, to its lowest frequency.

### Phase comparator 3 (PC3)

This is a positive edge-triggered sequential phase detector using an RS-type flip-flop. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of  $SIG_{IN}$  and  $COMP_{IN}$  are not important. The transfer characteristic of PC3, assuming ripple ( $f_r = f_i$ ) is suppressed,

$$\text{is: } V_{DEMOUT} = \frac{V_{CC}}{2\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

where  $V_{DEMOUT}$  is the demodulator output at pin 10;  
 $V_{DEMOUT} = V_{PC3OUT}$  (via low-pass filter).

$$\text{The phase comparator gain is: } K_p = \frac{V_{CC}}{2\pi} (V/r) .$$

The average output from PC3, fed to the VCO via the low-pass filter and seen at the demodulator output at pin 10 ( $V_{DEMOUT}$ ), is the resultant of the phase differences of  $SIG_{IN}$  and  $COMP_{IN}$  as shown in Fig.10. Typical waveforms for the PC3 loop locked at  $f_o$  are shown in Fig.11.

The phase-to-output response characteristic of PC3 (Fig.10) differs from that of PC2 in that the phase angle between  $SIG_{IN}$  and  $COMP_{IN}$  varies between  $0^\circ$  and  $360^\circ$  and is  $180^\circ$  at the centre frequency. Also PC3 gives a greater voltage swing than PC2 for input phase differences but as a consequence the ripple content of the VCO input signal is higher. The PLL lock range for this type of phase comparator and the capture range are dependent on the low-pass filter. With no signal present at  $SIG_{IN}$  the VCO adjusts, via PC3, to its lowest frequency.

## Phase-locked-loop with VCO

## 74HC/HCT4046A

## QUICK REFERENCE DATA

GND = 0 V;  $T_{amb} = 25\text{ }^{\circ}\text{C}$ 

SYMBOL	PARAMETER	CONDITIONS	TYPICAL		UNIT
			HC	HCT	
$f_o$	VCO centre frequency	$C_1 = 40\text{ pF}$ ; $R_1 = 3\text{ k}\Omega$ ; $V_{CC} = 5\text{ V}$	19	19	MHz
$C_I$	input capacitance (pin 5)		3.5	3.5	pF
$C_{PD}$	power dissipation capacitance per package	notes 1 and 2	24	24	pF

## Notes

- $C_{PD}$  is used to determine the dynamic power dissipation ( $P_D$  in  $\mu\text{W}$ ):  
 $P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o)$  where:  
 $f_i$  = input frequency in MHz.  
 $f_o$  = output frequency in MHz.  
 $C_L$  = output load capacitance in pF.  
 $V_{CC}$  = supply voltage in V.  
 $\sum (C_L \times V_{CC}^2 \times f_o)$  = sum of outputs.
- Applies to the phase comparator section only (VCO disabled). For power dissipation of the VCO and demodulator sections see Figs 22, 23 and 24.

## ORDERING INFORMATION

See *"74HC/HCT/HCU/HCMOS Logic Package Information"*.

## APPLICATIONS

- FM modulation and demodulation
- Frequency synthesis and multiplication
- Frequency discrimination
- Tone decoding
- Data synchronization and conditioning
- Voltage-to-frequency conversion
- Motor-speed control.

## PACKAGE OUTLINES

See *"74HC/HCT/HCU/HCMOS Logic Package Outlines"*.

AC WAVEFORMS

# Phase-locked-loop with VCO

74HC/HCT4046A

To obtain optimum temperature stability,  $C1$  must be as small as possible but larger than 100 pF.

Fig.18 Frequency stability of the VCO as a function of ambient temperature with supply voltage as a parameter.

— without offset ( $R2 = \infty$ ): (a)  $R1 = 3 \text{ k}\Omega$ ; (b)  $R1 = 10 \text{ k}\Omega$ ; (c)  $R1 = 300 \text{ k}\Omega$ .

- - - with offset ( $R1 = \infty$ ): (a)  $R2 = 3 \text{ k}\Omega$ ; (b)  $R2 = 10 \text{ k}\Omega$ ; (c)  $R2 = 300 \text{ k}\Omega$ .

In (b), the frequency stability for  $R1 = R2 = 10 \text{ k}\Omega$  at 5 V is also given (curve A). This curve is set by the total VCO bias current, and is not simply the addition of the two 10 k $\Omega$  stability curves.  $C1 = 100 \text{ pF}$ ;  $V_{VCO IN} = 0.5 V_{CC}$ .

Phase-locked-loop with VCO

74HC/HCT4046A

(d)  $R_2 = 3\text{ k}\Omega$   
 $R_1 = \infty$

(e)  $R_2 = 10\text{ k}\Omega$   
 $R_1 = \infty$

(f)  $R_2 = 300\text{ k}\Omega$   
 $R_1 = \infty$

To obtain optimum temperature stability, C1 must be as small as possible but larger than 100 pF.

Fig.18 Continued.

Phase-locked-loop with VCO

74HC/HCT4046A

(a)  $R_1 = 3\text{ k}\Omega$ ;  
 $C_1 = 40\text{ pF}$

(b)  $R_1 = 3\text{ k}\Omega$ ;  
 $C_1 = 100\text{ nF}$

(c)  $R_1 = 300\text{ k}\Omega$ ;  
 $C_1 = 40\text{ pF}$

(d)  $R_1 = 300\text{ k}\Omega$ ;  
 $C_1 = 100\text{ nF}$

To obtain optimum temperature stability,  $C_1$  must be as small as possible but larger than 100 pF.

Fig.19 Graphs showing VCO frequency ( $f_{VCO}$ ) as a function of the VCO input voltage ( $V_{COIN}$ ).

Phase-locked-loop with VCO

74HC/HCT4046A

APPLICATION INFORMATION

This information is a guide for the approximation of values of external components to be used with the 74HC/HCT4046A in a phase-lock-loop system.

References should be made to Figs 29, 30 and 31 as indicated in the table.

Values of the selected components should be within the following ranges:

- R1            between 3 kΩ and 300 kΩ;
- R2            between 3 kΩ and 300 kΩ;
- R1 + R2    parallel value > 2.7 kΩ;
- C1            greater than 40 pF.

## Phase-locked-loop with VCO

## 74HC/HCT4046A

To obtain optimum VCO performance,  $C_1$  must be as small as possible but larger than 100 pF.

Interpolation for various values of  $R_1$  can be easily calculated because a constant  $R_1 C_1$  product will produce almost the same VCO output frequency.

Fig.29 Typical value of VCO centre frequency ( $f_0$ ) as a function of  $C_1$ :  $R_2 = \infty$ ;  $V_{VCOIN} = 1/2 V_{CC}$ ; INH = GND;  $T_{amb} = 25^\circ\text{C}$ .

## Phase-locked-loop with VCO

## 74HC/HCT4046A

To obtain optimum VCO performance,  $C1$  must be as small as possible but larger than 100 pF.

Interpolation for various values of  $R2$  can be easily calculated because a constant  $R2C1$  product will produce almost the same VCO output frequency.

Fig.30 Typical value of frequency offset as a function of  $C1$ :  $R1 = \infty$ ;  $V_{\text{VCOIN}} = 1/2 V_{\text{CC}}$ ;  $\text{INH} = \text{GND}$ ;  $T_{\text{amb}} = 25\text{ }^{\circ}\text{C}$ .

Fig.31 Typical frequency lock range ( $2f_L$ ) versus the product  $R1C1$ :  $V_{VCOIN}$  range = 0.9 to  $(V_{CC} - 0.9)$  V;  $R2 = \infty$ ; VCO gain:

$$K_V = \frac{2f_L}{V_{VCOIN} \text{ range}} 2\pi \text{ (r/s/V)}.$$

## Phase-locked-loop with VCO

## 74HC/HCT4046A

**PLL design example**

The frequency synthesizer, used in the design example shown in Fig.32, has the following parameters:

Output frequency: 2 MHz to 3 MHz  
 frequency steps : 100 kHz  
 settling time : 1 ms  
 overshoot : < 20%

The open-loop gain is

$$H(s) \times G(s) = K_p \times K_f \times K_o \times K_n.$$

**Where:**

$K_p$  = phase comparator gain  
 $K_f$  = low-pass filter transfer gain  
 $K_o$  =  $K_v/s$  VCO gain  
 $K_n$  = 1/n divider ratio

The programmable counter ratio  $K_n$  can be found as follows:

$$N_{\min.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{2 \text{ MHz}}{100 \text{ kHz}} = 20$$

$$N_{\max.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{3 \text{ MHz}}{100 \text{ kHz}} = 30$$

The VCO is set by the values of R1, R2 and C1, R2 = 10 k $\Omega$  (adjustable). The values can be determined using the information in the section "DESIGN CONSIDERATIONS".

With  $f_o = 2.5$  MHz and  $f_L = 500$  kHz this gives the following values

( $V_{CC} = 5.0$  V):

R1 = 10 k $\Omega$

R2 = 10 k $\Omega$

C1 = 500 pF

The VCO gain is:

$$K_v = \frac{2f_L \times 2 \times \pi}{0.9 - (V_{CC} - 0.9)} =$$

$$= \frac{1 \text{ MHz}}{3.2} \times 2\pi \approx 2 \times 10^6 \text{ r/s/V}$$

The gain of the phase comparator is:

$$K_p = \frac{V_{CC}}{4 \times \pi} = 0.4 \text{ V/r.}$$

The transfer gain of the filter is given by:

$$K_f = \frac{1 + \tau_2 s}{1 + (\tau_1 + \tau_2) s}.$$

**Where:**

$$\tau_1 = R3C2 \text{ and } \tau_2 = R4C2.$$

The characteristics equation is:  
 $1 + H(s) \times G(s) = 0.$

This results in:

$$s^2 + \frac{1 + K_p \times K_v \times K_n \times \tau_2}{(\tau_1 + \tau_2)} s +$$

$$\frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)} = 0.$$

The natural frequency  $\omega_n$  is defined as follows:

$$\omega_n = \sqrt{\frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)}}.$$

and the damping value  $\zeta$  is defined as follows:

$$\zeta = \frac{1}{2\omega_n} \times \frac{1 + K_p \times K_v \times K_n \times \tau_2}{(\tau_1 + \tau_2)}$$

In Fig.33 the output frequency response to a step of input frequency is shown.

The overshoot and settling time percentages are now used to determine  $\omega_n$ . From Fig.33 it can be seen that the damping ratio  $\zeta = 0.45$  will produce an overshoot of less than 20% and settle to within 5% at  $\omega_n t = 5$ . The required settling time is 1 ms.

This results in:

$$\omega_n = \frac{5}{t} = \frac{5}{0.001} = 5 \times 10^3 \text{ r/s.}$$

Rewriting the equation for natural frequency results in:

$$(\tau_1 + \tau_2) = \frac{K_p \times K_v \times K_n}{\omega_n^2}.$$

The maximum overshoot occurs at  $N_{\max.}$ :

$$(\tau_1 + \tau_2) = \frac{0.4 \times 2 \times 10^6}{5000^2 \times 30} = 0.0011 \text{ s.}$$

When C2 = 470 nF, then

$$R4 = \frac{(\tau_1 + \tau_2) \times 2 \times \omega_n \times \zeta - 1}{K_p \times K_v \times K_n \times C2} = 315 \text{ } \Omega$$

now R3 can be calculated:

$$R3 = \frac{\tau_1}{C2} - R4 = 2 \text{ k}\Omega.$$

note

For an extensive description and application example please refer to application note ordering number 9398 649 90011.  
Also available a computer design program for PLL's ordering number 9398 961 10061.

Fig.33 Type 2, second order frequency step response.

Since the output frequency is proportional to the VCO control voltage, the PLL frequency response can be observed with an oscilloscope by monitoring pin 9 of the VCO. The average frequency response, as calculated by the Laplace method, is found experimentally by smoothing this voltage at pin 9 with a simple RC filter, whose time constant is long compared to the phase detector sampling rate but short compared to the PLL response time.

Fig.34 Frequency compared to the time response.

### SOLDERING

#### Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

#### DIP

##### SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $T_{stg\ max}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

##### REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

### SO, SSOP and TSSOP

#### REFLOW SOLDERING

Reflow soldering techniques are suitable for all SO, SSOP and TSSOP packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method.

Typical reflow temperatures range from 215 to 250 °C. Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

#### WAVE SOLDERING

Wave soldering can be used for all SO packages. Wave soldering is **not** recommended for SSOP and TSSOP packages, because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

If wave soldering is used - **and cannot be avoided for SSOP and TSSOP packages** - the following conditions must be observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow and must incorporate solder thieves at the downstream end.

#### Even with these conditions:

- **Only consider wave soldering SSOP packages that have a body width of 4.4 mm, that is SSOP16 (SOT369-1) or SSOP20 (SOT266-1).**
- **Do not consider wave soldering TSSOP packages with 48 leads or more, that is TSSOP48 (SOT362-1) and TSSOP56 (SOT364-1).**

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

#### REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

**DEFINITIONS**

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

**LIFE SUPPORT APPLICATIONS**

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
