2kx8 Asynchronous CMOS Static RAM

FN3001
Rev.1.00
March 1997

Features

- This Circuit is Processed in Accordance to MIL-STD-883 and is Fully Conformant Under the Provisions of Paragraph 1.2.1.
- Fast Access Time 70/90ns Max
- Low Standby Current 50 μ A Max
- Low Operating Current 70mA Max
- Data Retention at 2.0V 20 μ A Max
- TTL Compatible Inputs and Outputs
- JEDEC Approved Pinout (2716, 6116 Type)
- No Clocks or Strobes Required
- Wide Temperature Range. -55 $^{\circ}$ C to +125 $^{\circ}$ C
- Equal Cycle and Access Time
- Single 5V Supply
- Gated Inputs
 - No Pull-Up or Pull-Down Resistors Required

Description

The HM-65162/883 is a CMOS 2048 x 8 Static Random Access Memory manufactured using the Intersil Advanced SAJ1 V process. The device utilizes asynchronous circuit design for fast cycle time and ease of use. The pinout is the JEDEC 24 pin DIP, and 32 pad 8-bit wide standard which allows easy memory board layouts flexible to accommodate a variety of industry standard PROMs, RAMs, ROMs and EPROMs. The HM-65162/883 is ideally suited for use in microprocessor based systems with its 8-bit word length organization. The convenient output enable also simplifies the bus interface by allowing the data outputs to be controlled independent of the chip enable. Gated inputs lower operating current and also eliminate the need for pull-up or pull-down resistors.

Timing Waveforms

NOTE:

1. $\overline{W}$ is High for a Read Cycle.

FIGURE 1. READ CYCLE

Addresses must remain stable for the duration of the read cycle. To read, $\overline{G}$ and $\overline{E}$ must be $\leq V_{IL}$ and $\overline{W} \geq V_{IH}$. The output buffers can be controlled independently by $\overline{G}$ while $\overline{E}$ is low. To execute consecutive read cycles, $\overline{E}$ may be tied low

continuously until all desired locations are accessed. When $\overline{E}$ is low, addresses must be driven by stable logic levels and must not be in the high impedance state.

NOTE:

1. $\overline{G}$ is Low throughout Write Cycle.

FIGURE 2. WRITE CYCLE I

To write, addresses must be stable, $\overline{E}$ low and $\overline{W}$ falling low for a period no shorter than TWLWH. Data in is referenced with the rising edge of $\overline{W}$, (TDVWH and TWHDX). While addresses are changing, $\overline{W}$ must be high. When $\overline{W}$ falls low, the I/O pins are still in the output state for a period of TWLQZ

and input data of the opposite phase to the outputs must not be applied, (Bus contention). If $\overline{E}$ transitions low simultaneously with the $\overline{W}$ line transitioning low or after the $\overline{W}$ transition, the output will remain in a high impedance state. $\overline{G}$ is held continuously low.

Timing Waveforms (Continued)

FIGURE 3. WRITE CYCLE II

In this write cycle $\overline{G}$ has control of the output after a period, TGHQZ. $\overline{G}$ switching the output to a high impedance state allows data in to be applied without bus contention after

TGHQZ. When $\overline{W}$ transitions high, the data in can change after TWHDX to complete the write cycle.

Low Voltage Data Retention

Intersil CMOS RAMs are designed with battery backup in mind. Data retention voltage and supply current are guaranteed over temperature. The following rules ensure data retention:

1. Chip Enable ($\overline{E}$) must be held high during data retention; within $V_{CC} - 0.3V$ to $V_{CC} + 0.3V$.
2. On RAMs which have selects or output enables (e.g., S , $\overline{G}$), one of the selects or output enables should be held in the deselected state

to keep the RAM outputs high impedance, minimizing power dissipation.

3. Inputs which are to be held high (e.g., $\overline{E}$) must be kept between $V_{CC} + 0.3V$ and 70% of V_{CC} during the power up and down transitions.
4. The RAM can begin operation > 55ns after V_{CC} reaches the minimum operating voltage (4.5V).
