

Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

MAX951-MAX954

General Description

The MAX951-MAX954 feature combinations of a micropower operational amplifier, comparator, and reference in an 8-pin package. In the MAX951 and MAX952, the comparator's inverting input is connected to an internal 1.2V $\pm 2\%$ bandgap reference. The MAX953 and MAX954 are offered without an internal reference. The MAX951/MAX952 operate from a single 2.7V to 7V supply with a typical supply current of 7 μ A, while the MAX953/MAX954 operate from 2.4V to 7V with a 5 μ A typical supply current. Both the op amp and comparator feature a common-mode input voltage range that extends from the negative supply rail to within 1.6V of the positive rail, as well as output stages that swing Rail-to-Rail®.

The op amps in the MAX951/MAX953 are internally compensated to be unity-gain stable, while the op amps in the MAX952/MAX954 feature 125kHz typical bandwidth, 66V/ms slew rate, and stability for gains of 10V/V or greater. These op amps have a unique output stage that enables them to operate with an ultra-low supply current while maintaining linearity under loaded conditions. In addition, they have been designed to exhibit good DC characteristics over their entire operating temperature range, minimizing input-referred errors.

The comparator output stage of these devices continuously sources as much as 40mA. The comparators eliminate power-supply glitches that commonly occur when changing logic states, minimizing parasitic feedback and making the devices easier to use. In addition, they contain ± 3 mV internal hysteresis to ensure clean output switching, even with slow-moving input signals.

Applications

Instruments, Terminals, and Bar-Code Readers
Battery-Powered Systems
Automotive Keyless Entry
Low-Frequency, Local-Area Alarms/Detectors
Photodiode Preamps
Smart Cards
Infrared Receivers for Remote Controls
Smoke Detectors and Safety Sensors

Features

- ◆ Op Amp + Comparator + Reference in an 8-Pin μ MAX Package (MAX951/MAX952)
- ◆ 7 μ A Typical Supply Current (Op Amp + Comparator + Reference)
- ◆ Comparator and Op Amp Input Range Includes Ground
- ◆ Outputs Swing Rail-to-Rail
- ◆ 2.4V to 7V Supply Voltage Range
- ◆ Unity-Gain Stable and 125kHz Decompensated $A_V \geq 10$ V/V Op Amp Options
- ◆ Internal 1.2V $\pm 2\%$ Bandgap Reference
- ◆ Internal Comparator Hysteresis
- ◆ Op Amp Capable of Driving up to 1000pF Load

6	—	REF	1.200V Reference Output. Also connected to inverting comparator input.
—	6	COMPIN-	Inverting Comparator Input
7	7	COMPOUT	Comparator Output
8	8	VDD	Positive Supply

Functional Diagrams

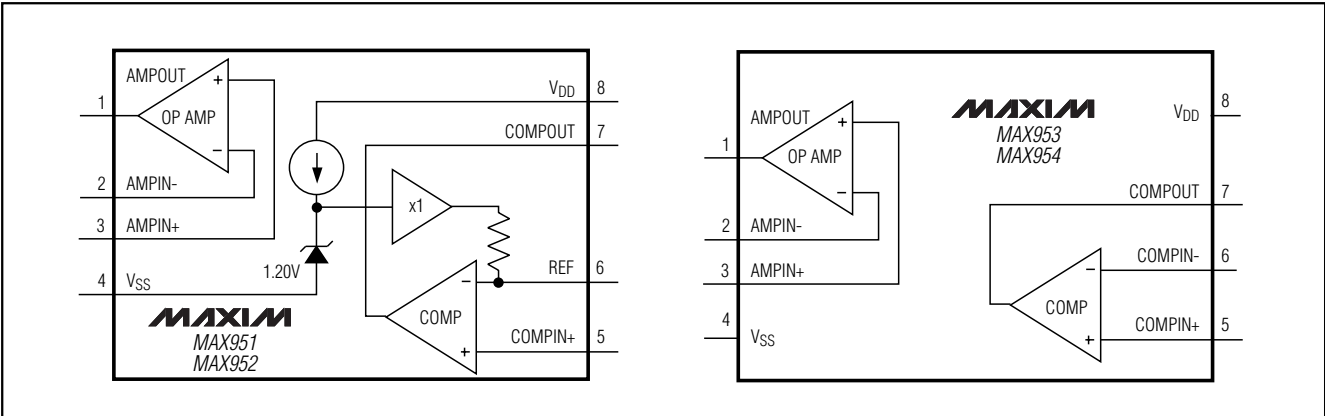

Figure 1. MAX951-MAX954 Functional Diagrams

Detailed Description

The MAX951-MAX954 are combinations of a micropower op amp, comparator, and reference in an 8-pin package, as shown in Figure 1. In the MAX951/MAX952, the comparator's negative input is connected to a 1.20V $\pm 2\%$ bandgap reference. All four devices are optimized to operate from a single supply. Supply current is less than 10 μ A (7 μ A typical) for the MAX951/MAX952 and less than 8 μ A (5 μ A typical) for the MAX953/MAX954.

Op Amp

The op amps in the MAX951/MAX953 are internally compensated to be unity-gain stable, while the op amps in the MAX952/MAX954 feature 125kHz typical gain bandwidth, 66V/ms slew rate, and stability for gains of 10V/V or greater. All these op amps feature

high-impedance differential inputs and a common-mode input voltage range that extends from the negative supply rail to within 1.6V of the positive rail. They have a CMOS output stage that swings rail to rail and is driven by a proprietary high gain stage, which enables them to operate with an ultra-low supply current while maintaining linearity under loaded conditions. Careful design results in good DC characteristics over their entire operating temperature range, minimizing input referred errors.

Comparator

The comparator in the MAX951-MAX954 has a high-impedance differential input stage with a common-mode input voltage range that extends from the negative supply rail to within 1.6V of the positive rail. Their CMOS output stage swings rail-to-rail and can

Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

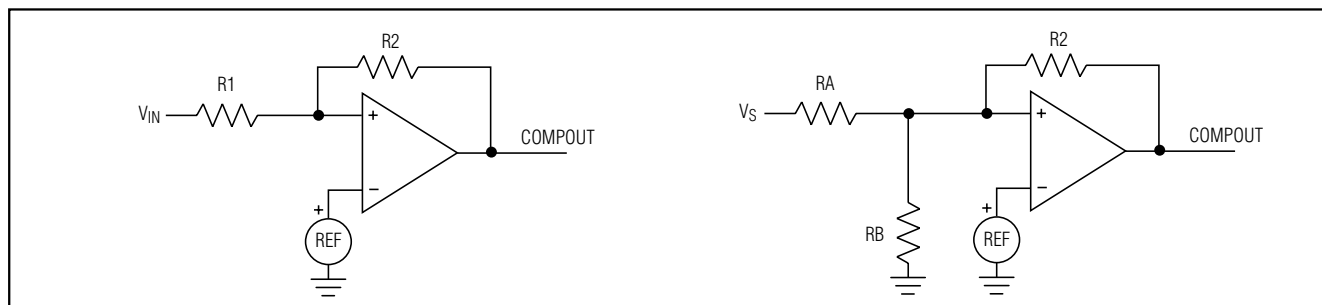

Figure 2. External Hysteresis

continuously source as much as 40mA. The comparators eliminate power-supply glitches that commonly occur when changing logic states, minimizing parasitic feedback and making them easier to use. In addition, they include internal hysteresis ($\pm 3\text{mV}$) to ensure clean output switching, even with slow-moving input signals. The inputs can be taken above and below the supply rails up to 300mV without damage. Input voltages beyond this range can forward bias the ESD-protection diodes and should be avoided.

The MAX951-MAX954 comparator outputs swing rail-to-rail (from V_{DD} to V_{SS}). TTL compatibility is assured by using a $5\text{V} \pm 10\%$ supply.

The MAX951-MAX954 comparators continuously output source currents as high as 40mA and sink currents of over 5mA, while keeping quiescent currents in the microampere range. The output can source 100mA (at $V_{DD} = 5\text{V}$) for short pulses, as long as the package's maximum power dissipation is not exceeded. The output stage does not generate crowbar switching currents during transitions; this minimizes feedback through the supplies and helps ensure stability without bypassing.

Reference

The internal reference in the MAX951/MAX952 has an output of 1.20V with respect to V_{SS} . Its accuracy is $\pm 2\%$ in the -40°C to $+85^\circ\text{C}$ temperature range. It is comprised of a trimmed bandgap reference fed by a proportional-to-absolute-temperature (PTAT) current source and buffered by a micropower unity-gain amplifier. The REF output is typically capable of sourcing and sinking $20\mu\text{A}$. Do not bypass the reference output. The reference is stable for capacitive loads less than 100pF .

Applications Information

The micropower MAX951-MAX954 are designed to extend battery life in portable instruments and add functionality in power-limited industrial controls. Following are some practical considerations for circuit design and layout.

Comparator Hysteresis

Hysteresis increases the comparator's noise immunity by increasing the upper threshold and decreasing the lower threshold. The comparator in these devices contain a $\pm 3\text{mV}$ wide internal hysteresis band to ensure clean output switching, even with slow-moving signals.

When necessary, hysteresis can be increased by using external resistors to add positive feedback, as shown in Figure 2. This circuit increases hysteresis at the expense of more supply current and a slower response. The design procedure is as follows:

- 1) Set R_2 . The leakage current in COMPIN^+ is less than 5nA (up to $+85^\circ\text{C}$), so current through R_2 can be as little as 500nA and still maintain good accuracy. If $R_2 = 2.4\text{M}\Omega$, the current through R_2 at the upper trip point is V_{REF}/R_2 or 500nA .
- 2) Choose the width of the hysteresis band. In this example choose $V_{\text{EHYST}} = 50\text{mV}$.

$$R_1 = R_2 \frac{[V_{\text{EHYST}} - 2V_{\text{IHYST}}]}{(V_{DD} + 2V_{\text{IHYST}})}$$

where the internal hysteresis is $V_{\text{IHYST}} = 3\text{mV}$.

- 3) Determine R_1 . If the supply voltage is 5V , then $R_1 = 24\text{k}\Omega$.
- 4) Check the hysteresis trip points. The upper trip point is

$$V_{\text{IN(H)}} = \frac{(R_1 + R_2)}{R_2} (V_{\text{REF}} + V_{\text{IHYST}})$$

or 1.22V in our example. The lower trip point is 50mV less, or 1.17V in our example.

If a resistor divider is used for R_1 , the calculations should be modified using a Thevenin equivalent model.

- 5) Determine R_A :

Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

Figure 3. Compensation for Feedback-Node Capacitance

$$R_A \approx R_2 \frac{V_{SHYST}}{V_{DD}}, \text{ for } V_{SHYST} \gg V_{IHYST}$$

In the example, R_A is again 24k Ω .

- 6) Select the upper trip point $V_{S(H)}$. Our example is set at 4.75V.
- 7) Calculate R_B .

$$R_B = \frac{(V_{REF} + V_{IHYST})(R_2)(R_A)}{(R_2)(V_{S(H)}) - (V_{REF} + V_{IHYST})(R_A + R_2)}$$

where R_B is 8.19k Ω , or approximately 8.2k Ω .

Input Noise Considerations

Because low power requirements often demand high-impedance circuits, effects from radiated noise are more significant. Thus, traces between the op amp or comparator inputs and any resistor networks attached should be kept as short as possible.

Crosstalk Reference

Internal crosstalk to the reference from the comparator is package dependent. Typical values ($V_{DD} = 5V$) are 45mV for the plastic DIP package and 32mV for the SO package. Applications using the reference for the op amp or external circuitry can eliminate this crosstalk by using a simple RC lowpass filter, as shown in Figure 5.

Op Amp

Internal crosstalk to the op amp from the comparator is package dependent, but not input-referred. Typical values ($V_{DD} = 5V$) are 4mV for the plastic DIP package and 280 μV for the SO package.

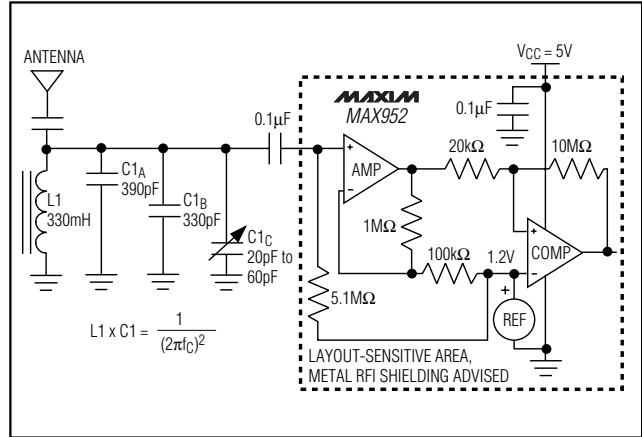

Figure 4. Low-Frequency Radio Receiver Application

Op Amp Stability and Board Layout Considerations

Unlike other industry-standard micropower CMOS op amps, the op amps in the MAX951-MAX954 maintain stability in their minimum gain configuration while driving heavy capacitive loads, as demonstrated in the MAX951/MAX953 Op Amp Percent Overshoot vs. Capacitive Load graph in the *Typical Operating Characteristics*.

Although this family is primarily designed for low-frequency applications, good layout is extremely important. Low-power, high-impedance circuits may increase the effects of board leakage and stray capacitance. For example, the combination of a 10M Ω resistance (from leakage between traces on a contaminated, poorly designed PC board) and a 1pF stray capacitance provides a pole at approximately 16kHz, which is near the amplifier's bandwidth. Board routing and layout should minimize leakage and stray capacitance. In some cases, stray capacitance may be unavoidable and it may be necessary to add a 2pF to 10pF capacitor across the feedback resistor to compensate; select the smallest capacitor value that ensures stability.

Input Overdrive

With 100mV overdrive, comparator propagation delay is typically 6 μs . The *Typical Operating Characteristics* show propagation delay for various overdrive levels.

Supply current can increase when the op amp in the MAX951-MAX954 is overdriven to the negative supply rail. For example, when connecting the op amp as a comparator and applying a -100mV input overdrive, supply current rises by around 15 μA and 32 μA for supply voltages of 2.8V and 7V, respectively.

Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

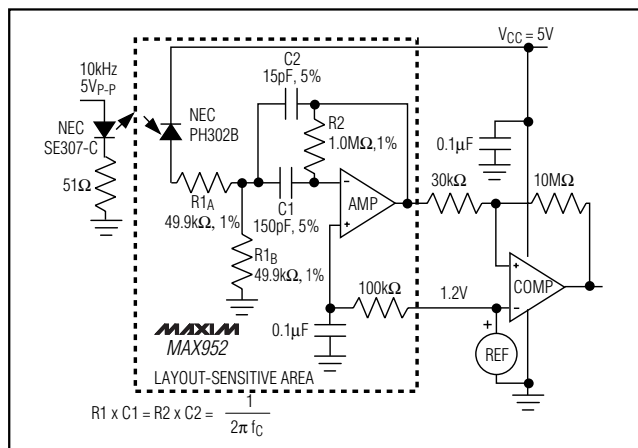

Figure 5. Infrared Receiver Application

Power-Supply Bypassing

Power-supply bypass capacitors are not required if the supply impedance is low. For single-supply applications, it is good general practice to bypass V_{DD} with a 0.1μF capacitor to ground. Do not bypass the reference output.

Applications Circuits

Low-Frequency Radio Receiver for Alarms and Detectors

The circuit in Figure 4 is useful as a front end for low-frequency RF alarms. The unshielded inductor (M7334-ND from Digikey) is used with capacitors C1A, C1B, and C1C in a resonant circuit to provide frequency selectivity. The op amp from a MAX952 amplifies the signal received. The comparator improves noise immunity, provides a signal strength threshold, and translates the received signal into a pulse train. Carrier frequencies are limited to around 10kHz. 10kHz is used in the example in Figure 4.

The layout and routing of components for the amplifier should be tight to minimize 60Hz interference and crosstalk from the comparator. Metal shielding is recommended to prevent RFI from the comparator or digital circuitry from exciting the receiving antenna. The transmitting antenna can be long parallel wires spaced about 7.2cm apart, with equal but opposite currents. Radio waves from this antenna will be detectable when the receiver is brought within close proximity, but cancel out at greater distances.

Infrared Receiver Front End for Remote Controls and Data Links

The circuit in Figure 5 uses the MAX952 as a pin photodiode preamplifier and discriminator for an infrared

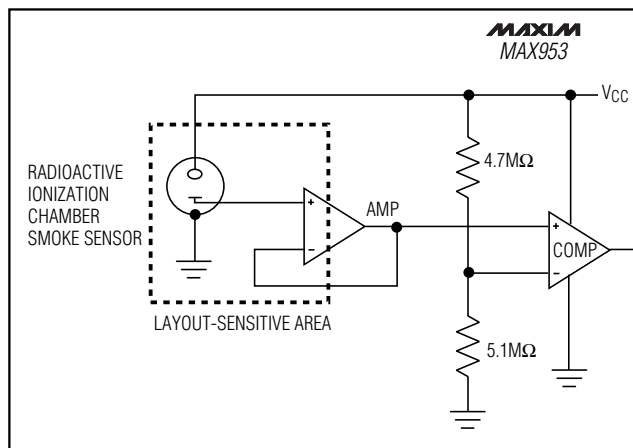

Figure 6. Sensor Preamp and Alarm Trigger Application

receiver. The op amp is configured as a Delyiannis-Friend bandpass filter to reduce disturbances from noise and eliminate low-frequency interference from sunlight, fluorescent lights, etc. This circuit is applicable for TV remote controls and low-frequency data links up to 20kbps. Carrier frequencies are limited to around 10kHz. 10kHz is used in the example circuit.

Component layout and routing for the amplifier should be tight to reduce stray capacitance, 60Hz interference, and RFI from the comparator. Crosstalk from comparator edges will distort the amplifier signal. In order to minimize the effect, a lowpass RC filter is added to the connection from the reference to the non-inverting input of the op amp.

Sensor Preamp and Alarm Trigger for Smoke Detectors

The high-impedance CMOS inputs of the MAX951–MAX954 op amps are ideal for buffering high-impedance sensors, such as smoke detector ionization chambers, piezoelectric transducers, gas detectors, and pH sensors. Input bias currents are typically less than 3pA at room temperature. A 5μA typical quiescent current for the MAX953 will minimize battery drain without resorting to complex sleep schemes, allowing continuous monitoring and immediate detection.

Ionization-type smoke detectors use a radioactive source, such as Americium, to ionize smoke particles. A positive voltage on a plate attached to the source repels the positive smoke ions and accelerates them toward an outer electrode connected to ground. Some ions collect on an intermediate plate. With careful design, the voltage on this plate will stabilize at a little less than one-half the supply voltage under normal conditions, but rise higher when smoke increases the ion current. This voltage is buffered

Ultra-Low-Power, Single-Supply Op Amp + Comparator + Reference

by the high-input-impedance op amp of a MAX951 (Figure 6). The comparator and resistor voltage divider set an alarm threshold to indicate a fire.

Design and fabrication of the connection from the intermediate plate of the ionization chamber to the noninverting input of the op amp is critical, since the impedance of this node must be well above 50MΩ. This connection must be as short and direct as possible to prevent charge leakage and 60Hz interference. Where possible, the grounded outer electrode or chassis of the ionization chamber should shield this connection to reduce 60Hz interference. Pay special attention to board cleaning, to prevent leakage due to ionic compounds such as chlorides, flux, and other contaminants from the manufacturing process. Where applicable, a coating of high-purity wax may be used to insulate this connection and prevent leakage due to surface moisture or an accumulation of dirt.

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX951C/D	0°C to +70°C	Dice*
MAX951EPA	-40°C to +85°C	8 Plastic Dip
MAX951ESA	-40°C to +85°C	8 SO
MAX951EUA	-40°C to +85°C	8 μMAX
MAX951MJA	-55°C to +125°C	8 Cerdip**
MAX952C/D	0°C to +70°C	Dice*
MAX952EPA	-40°C to +85°C	8 Plastic Dip
MAX952ESA	-40°C to +85°C	8 SO
MAX952EUA	-40°C to +85°C	8 μMAX
MAX952MJA	-55°C to +125°C	8 Cerdip**
MAX953C/D	0°C to +70°C	Dice*
MAX953EPA	-40°C to +85°C	8 Plastic Dip
MAX953ESA	-40°C to +85°C	8 SO
MAX953EUA	-40°C to +85°C	8 μMAX
MAX953MJA	-55°C to +125°C	8 Cerdip**
MAX954C/D	0°C to +70°C	Dice*
MAX954EPA	-40°C to +85°C	8 Plastic Dip
MAX954ESA	-40°C to +85°C	8 SO
MAX954EUA	-40°C to +85°C	8 μMAX
MAX954MJA	-55°C to +125°C	8 Cerdip**

*Dice are tested at $T_A = +25^\circ\text{C}$, DC parameters only.

**Contact factory for availability and processing to MIL-STD-883.
