Description

The IDT709149 is a high-speed 4K x 9 bit synchronous Dual-Port SRAM. The memory array is based on Dual-Port memory cells to allow simultaneous access from both ports. Registers on control, data, and address inputs provide low set-up and hold times. The timing latitude provided by this approach will allow systems to be designed with very short cycle times. This device has been optimized for applications having unidirectional data flow or bi-directional data flow in bursts, by utilizing input data registers.

The IDT709149 utilizes a 9-bit wide data path to allow for parity at the user's option. This feature is especially useful in data communication applications where it is necessary to use a parity bit for transmission/reception error checking.

Fabricated using IDT's CMOS high-performance technology, these Dual-Ports typically operate on only 800mW of power at maximum high-speed clock-to-data output times as fast as 8ns. An automatic power down feature, controlled by $\overline{CE}$, permits the on-chip circuitry of each port to enter a very low standby power mode.

The IDT709149 is packaged in an 80-pin TQFP.

NOTES:

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
- V_{TERM} must not exceed $V_{CC} + 10\%$ for more than 25% of the cycle time or 10ns maximum, and is limited to $\leq 20mA$ for the period of $V_{TERM} \geq V_{CC} + 10\%$.

Functional Description

The IDT709149 provides a true synchronous Dual-Port Static RAM interface. Registered inputs provide very short set-up and hold times on address, data, and all critical control inputs. All internal registers are clocked on the rising edge of the clock signal. An asynchronous output enable is provided to ease asynchronous bus interfacing.

The internal write pulse width is dependent only on the low to high transitions of the clock signal to initiate a write allowing the shortest

possible realized cycle times. Clock enable inputs are provided to stall the operation of the address and data input registers without introducing clock skew for very fast interleaved memory applications.

A HIGH on the $\overline{CE}$ input for one clock cycle will power down the internal circuitry to reduce static power consumption.

When pipelined mode is enabled, two cycles are required with $\overline{CE}$ LOW to reactivate the outputs.

NOTES:

1. 'H' = HIGH voltage level steady state, 'h' = HIGH voltage level one set-up time prior to the LOW-to-HIGH clock transition, 'L' = LOW voltage level steady state 'l' = LOW voltage level one set-up time prior to the LOW-to-HIGH clock transition, 'X' = Don't care, 'NC' = No change
2. $\overline{CLKEN}$ = V_{IL} must be clocked in during Power-Up.
3. Control signals are initiated and terminated on the rising edge of the CLK, depending on their input level. When R/W and $\overline{CE}$ are LOW, a write cycle is initiated on the LOW-to-HIGH transition of the CLK. Termination of a write cycle is done on the next LOW-to-HIGH transition of the CLK.
4. The register outputs are internal signals from the register inputs being clocked in or disabled by $\overline{CLKEN}$.
