

## FEATURES

- Peak efficiency: 92%
- Operating frequency: 6 MHz
- Typical quiescent current in auto mode: 36  $\mu$ A
- Fixed output voltage: 1.8 V, 1.82 V, 1.85 V, 1.875 V, 2.3 V
- Maximum guaranteed load current: 600 mA at  $V_{IN} = 2.7$  V to 5.5 V
- Input voltage: 2.3 V to 5.5 V
- Typical shutdown supply current: 0.3  $\mu$ A
- Automatic power-saving mode
- Compatible with tiny multilayer inductors
- Internal synchronous rectifier
- Internal compensation
- Internal soft start
- Output to ground short-circuit protection
- Cycle-by-cycle current-limit protection
- Enable/shutdown logic input
- Undervoltage lockout
- Thermal shutdown protection
- Ultrasmall 6-ball, 0.4 mm pitch, 1.17 mm<sup>2</sup> WLCSP

## APPLICATIONS

- Mobile phones
- Digital cameras
- Digital audio
- Portable equipment

## GENERAL DESCRIPTION

The ADP2121 is a high frequency, low quiescent current step-down dc-to-dc converter optimized for portable applications in which board area and battery life are critical constraints. The 6 MHz operating frequency enables the use of tiny ceramic inductors and capacitors. Additionally, the synchronous rectification improves efficiency and results in fewer external components.

At high load currents, the device uses a voltage regulating pulse-width modulation (PWM) mode that maintains a constant frequency with excellent stability and transient response. In forced PWM mode, the converter continues operating in PWM for light loads. At light load conditions in auto mode, the ADP2121 can automatically enter a power-saving mode that uses pulse-frequency modulation (PFM) to reduce the effective switching frequency and ensure the longest battery life in portable applications. During logic controlled shutdown ( $EN \leq 0.4$  V), the input is disconnected from the output and draws less than 0.3  $\mu$ A current (typical) from the source.

## TYPICAL APPLICATION CIRCUIT

\*FOR OUTPUT VOLTAGE = 2.3 V, INPUT VOLTAGE = 2.9 V TO 5.5 V.

Figure 1.

Figure 2. Efficiency vs. Load Current for Each Voltage Option

The ADP2121 has an input voltage range of 2.3 V to 5.5 V (2.9 V to 5.5 V for  $V_{OUT} = 2.3$  V), allowing the use of a single Li+/Li-polymer cell, 3-cell alkaline or Ni-MH cell, and other standard power sources. The converter can source up to 600 mA and is internally compensated to minimize external components. Other key features, such as cycle-by-cycle peak current limit, soft start, undervoltage lockout (UVLO), output-to-ground short-circuit protection, and thermal shutdown, protect the internal and external circuit components.

Table 1. Output Voltage Options

Input Voltage Range (V)	Typical Start-Up Time ( $\mu$ s)	Fixed Output Voltage (V)
2.3 to 5.5	75	1.8, 1.85, 1.875
2.3 to 5.5	275	1.82
2.9 to 5.5	100	2.3

<sup>1</sup> All limits at temperature extremes are guaranteed via correlation using standard statistical quality control (SQC); typical values are at  $T_A = 25^\circ\text{C}$ .

<sup>2</sup> Guaranteed by design. The maximum output current guarantee for  $2.3\text{ V}$  to  $2.5\text{ V}$  increases linearly from  $300\text{ mA}$  to  $500\text{ mA}$ . The maximum output current guarantee for  $2.5\text{ V}$  to  $2.7\text{ V}$  increases linearly from  $500\text{ mA}$  to  $600\text{ mA}$ . For greater than  $2.7\text{ V}$ , the maximum output current guarantee is  $600\text{ mA}$ .

<sup>3</sup> Transients not included in voltage accuracy specifications. For PFM mode, the  $V_{OUT}$  accuracy specification is for the upper point of the ripple.

<sup>4</sup> The load regulation typical value includes all voltage options. The typical value is different for each voltage option, but can be up to  $-0.2\%/A$ .

<sup>5</sup> Typical value characterized on bench. Maximum specification guaranteed by design.  $C_{IN} = 2.2\text{ }\mu\text{F}$  (GRM155R60J225M),  $L = 0.47\text{ }\mu\text{H}$  (LQM2HPNR47MG0L),  $C_{OUT} = 4.7\text{ }\mu\text{F}$  (GRM155R60J475ME87D).

## ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
VIN to GND	–0.3 V to +6 V
EN, MODE to GND	–0.3 V to VIN
FB, SW to GND	–0.3 V to VIN + 0.2 V
Operating Ambient Temperature Range ( $I_{LOAD} \leq 600$ mA)	–40°C to +85°C
Operating Junction Temperature Range	–40°C to +125°C
Storage Temperature	–45°C to +150°C
Soldering Conditions	JEDEC J-STD-020
ESD (Electrostatic Discharge) Human Body Model	±4 kV

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### THERMAL DATA

Absolute maximum ratings apply individually only, not in combination. The ADP2121 can be damaged when the junction temperature limits are exceeded. Monitoring ambient temperature does not guarantee that the junction temperature ( $T_J$ ) is within the specified temperature limits. In applications with high power dissipation and poor PCB thermal resistance, the maximum ambient temperature may need to be derated. In applications with moderate power dissipation and low PCB thermal resistance, the maximum ambient temperature can exceed the maximum limit as long as the junction temperature is within specification limits.

The junction temperature ( $T_J$ ) of the device is dependent on the ambient temperature ( $T_A$ ), the power dissipation of the device ( $P_D$ ), and the junction-to-ambient thermal resistance of the package ( $\theta_{JA}$ ). Maximum junction temperature ( $T_J$ ) is calculated from the ambient temperature ( $T_A$ ) and power dissipation ( $P_D$ ) using the following formula:

$$T_J = T_A + (P_D \times \theta_{JA})$$

The junction-to-ambient thermal resistance ( $\theta_{JA}$ ) of the package is based on modeling and calculation using a 2- and 4-layer board. The junction-to-ambient thermal resistance is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, close attention to thermal board design is required.

The value of  $\theta_{JA}$  may vary, depending on PCB material, layout, and environmental conditions. Refer to JEDEC JESD51-9 for detailed information about board construction.

### THERMAL RESISTANCE

The junction-to-ambient thermal resistance of the system ( $\theta_{JA}$ ) is specified for worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 4.

Package Type	$\theta_{JA}$	Unit
6-Ball WLCSP		
2-Layer Board	198	°C/W
4-Layer Board	105	°C/W

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 3. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
A1	MODE	Mode Select. This pin toggles between auto mode (PFM and PWM switching) and PWM mode. Set MODE low to allow the part to operate in auto mode. Pull MODE high to force the part to operate in PWM mode. The voltage applied to MODE must never be higher than the voltage applied to VIN. Do not leave this pin floating.
B1	SW	Switch Node.
C1	FB	Feedback Divider Input. Connect the output capacitor from FB to GND as close as possible to the ADP2121 to set the output voltage ripple and to complete the control loop.
A2	VIN	Power Supply Input. Connect the input capacitor from VIN to GND as close as possible to the ADP2121.
B2	EN	Enable. Pull this pin high to enable the part. Set this pin low to disable the part. Do not leave this pin floating.
C2	GND	Ground Pin.

## TYPICAL PERFORMANCE CHARACTERISTICS

$V_{IN} = 3.6\text{ V}$ ,  $V_{OUT} = 1.82\text{ V}$ ,  $L = 0.47\text{ }\mu\text{H}$  (1800 mA, 1008, LQM2HPNR47MG0L),  $C_{IN} = 2.2\text{ }\mu\text{F}$  (6.3 V, 0402, X5R, GRM155R60J225M),  $C_{OUT} = 4.7\text{ }\mu\text{F}$  (6.3 V, 0402, X5R, GRM155R60J475ME87D),  $EN = V_{IN}$ , and  $T_A = 25^\circ\text{C}$ , unless otherwise noted.

## THEORY OF OPERATION

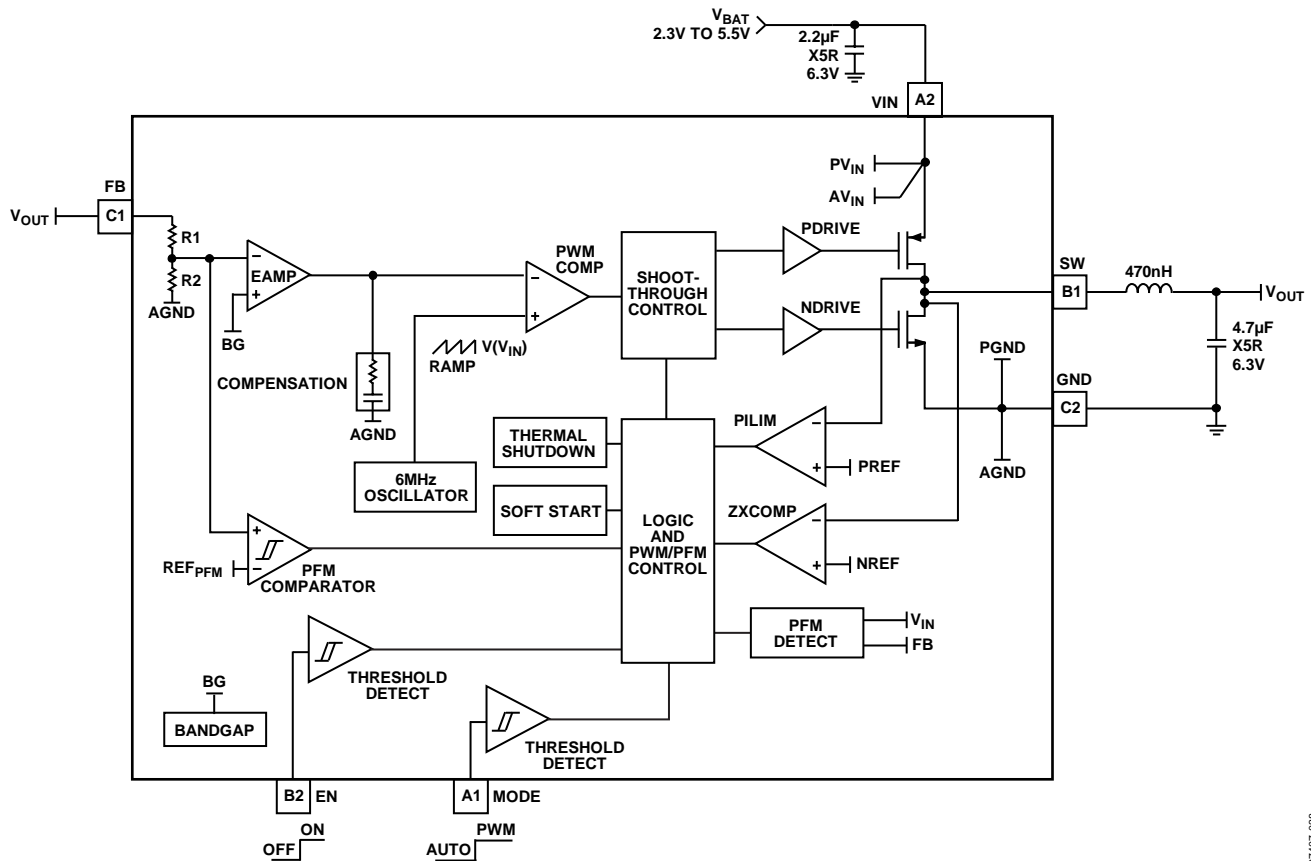

Figure 51. Internal Block Diagram

## OVERVIEW

The ADP2121 is a high efficiency, synchronous step-down dc-to-dc converter that provides up to 600 mA of continuous output current. It operates from a 2.3 V to 5.5 V input voltage for the 1.8 V, 1.82 V, 1.85 V, and 1.875 V (typical) fixed-output voltages, and from a 2.9 V to 5.5 V input voltage for the 2.3 V (typical) output voltage. The 6 MHz operating frequency enables the use of tiny external components. The internal control schemes of the ADP2121 give excellent stability and transient response. External control for mode selection and device enable provide power-saving options that are aided by internal features such as synchronous rectification and compensation. Other internal features, such as cycle-by-cycle peak current limit, soft start, undervoltage lockout, output-to-ground short-circuit protection, and thermal shutdown, protect the internal and external circuit components.

## MODE SELECTION

The ADP2121 has two modes of operation (PWM mode and auto mode), determined by the state of the MODE pin.

Pull the MODE pin high to force the converter to operate in PWM mode regardless of the output current. Otherwise, set MODE low to allow the converter to automatically enter the power-saving PFM mode at light load currents. Do not leave this pin floating. The MODE pin is not designed for dynamic control and must not be changed after the ADP2121 is enabled.

### Pulse-Width Modulation (PWM) Mode

The PWM mode forces the part to maintain a fixed frequency of 6 MHz (typical) over all load conditions. The ADP2121 uses a hybrid proprietary voltage mode control scheme to control the duty cycle over load current and line voltage variation. This control provides excellent stability, transient response, and output regulation but results in lower efficiencies at light load currents.

Figure 52. Typical PWM Operation

### Auto Mode (PFM and PWM Switching)

Auto mode is a power-saving feature that enables the converter to switch between PWM and PFM in response to the output load. Auto mode is enabled when the MODE pin is pulled low. In auto mode, the ADP2121 operates in PFM mode for light load currents and switches to PWM mode for medium and heavy load currents. Figure 53 uses the typical threshold values of the 1.82 V output voltage option to demonstrate the behavior of the ADP2121 in auto mode. The threshold values shift accordingly for other output voltages.

\*PFM AND PWM THRESHOLD VARIES WITH INPUT VOLTAGE.  
SEE FIGURE 22, FIGURE 23 and FIGURE 24 FOR TYPICAL VALUES.

Figure 53. PFM-to-PWM Transition Point,  $V_{OUT} = 1.82\text{ V}$ 

### Pulse Frequency Modulation (PFM)

When the converter is operating under light load conditions, the effective switching frequency and supply current are decreased and varied using PFM to regulate the output voltage. This results in improved efficiencies and lower quiescent currents. In PFM mode, the converter only switches when necessary to keep the output voltage within the PFM limits set by an internal comparator (see Figure 53). Switching stops when the upper limit is reached and resumes when the lower limit is reached.

When the upper level is reached, the output stage and oscillator turn off to reduce the quiescent current. During this stage, the output capacitor supplies the current to the load. As the output capacitor discharges and the output voltage reaches the lower PFM comparator threshold, switching resumes and the process

repeats. The output voltage, switching node voltage, and inductor current during this process are shown in Figure 54.

Figure 54. Typical PFM Operation

### Mode Transition

When the MODE pin is low, the converter switches between PFM and PWM modes automatically to maintain optimal transient response and efficiency. The mode transition point depends on the input voltage. Hysteresis exists in the transition point to prevent instability and decreased efficiencies that could result if the converter were able to oscillate between PFM and PWM for a fixed input voltage and load current. See Figure 22, Figure 23, and Figure 24 for typical values.

A switch from PFM to PWM occurs when the output voltage dips below the nominal value of the output voltage option. Switching to PWM allows the converter to maintain efficiency and supply a larger current to the load.

The switch from PWM to PFM occurs when the output current is below the PFM threshold for multiple consecutive switching cycles. Switching to PFM allows the converter to save power by supplying the lighter load current with fewer switching cycles.

Figure 53 shows that the output voltage in PFM mode is slightly higher to keep the ADP2121 from oscillating between modes, ensuring stable operation.

### ENABLE/SHUTDOWN

The EN input turns the ADP2121 on or off. Connect EN to GND or logic low to shut down the part and reduce the current consumption to 1.0  $\mu\text{A}$  (maximum). Connect EN to VIN or to logic high to enable the part. Do not leave this pin floating.

### INTERNAL CONTROL FEATURES

#### Overcurrent Protection

To ensure that excessively high currents do not damage the inductor, the ADP2121 incorporates cycle-by-cycle overcurrent protection. This function is accomplished by monitoring the instantaneous peak current on the power PMOS switch. If this current exceeds the maximum level (1 A typical), the PMOS is immediately turned off. This minimizes the potential for damage to power components during certain faults and transient events. The value listed in Table 2 is an open loop dc tested value. Inherent

delays in the current-limit comparator allow a slight increase and variation in this specification.

### Soft Start

To prevent excessive input inrush current at startup, the ADP2121 operates with an internal soft start. When EN goes high, or when the part recovers from a fault (UVLO, TSD, or short-circuit protection), a soft start timer begins. The soft start timer corresponds to the maximum soft start period for the given fixed output voltage. During this time, the peak current limit is gradually increased to its maximum. As seen in Figure 40 through Figure 45, the output voltage passes through several stages to ensure that the converter is able to start up effectively and in proper sequence. After the soft start period has expired, the peak current limit remains at 1 A (typical), and the part enters the operating mode determined by the MODE pin.

### Synchronous Rectification

In addition to the P-channel MOSFET switch, the ADP2121 includes an N-channel MOSFET switch to build the synchronous rectifier. The synchronous rectifier improves efficiency, especially for small load currents, and reduces cost and board space by eliminating the need for an external rectifier.

### Compensation

The control loop is internally compensated to deliver maximum performance with no additional external components. The ADP2121 is designed to work with 0.47  $\mu\text{H}$  chip inductors and 4.7  $\mu\text{F}$  capacitors (see Table 6, Table 7, and Table 8.) Other values may reduce performance and/or stability.

### Undervoltage Lockout (UVLO)

If the input voltage is below the UVLO threshold, the ADP2121 automatically turns off the power switches and places the part into a low power consumption mode. This prevents potentially erratic operation at low input voltages. The UVLO levels have approximately 100 mV of hysteresis to ensure glitch-free startup.

### Output Short-Circuit Protection

If the output voltage is inadvertently shorted to GND, a standard dc-to-dc controller delivers maximum power into that short. This may result in a potentially catastrophic failure. To prevent this, the ADP2121 senses when the output voltage is below the short-circuit protection threshold (typically 1.24 V).

At this point, the controller turns off for approximately 1.8 ms ( $V_{\text{OUT}} = 1.82\text{ V}$ ), 0.44 ms ( $V_{\text{OUT}} = 1.8\text{ V}$  and 1.85 V), or 0.48 ms ( $V_{\text{OUT}} = 2.3\text{ V}$ ), and then automatically initiates a soft start sequence. This cycle repeats until the short is removed or the part is disabled. This dramatically reduces the power delivered into the short circuit, yet still allows the converter to recover if the fault is removed.

Figure 55. Output Short-Circuit Protection,  $V_{\text{OUT}} = 1.82\text{ V}$

### Thermal Shutdown (TSD) Protection

The ADP2121 also includes TSD protection. If the die temperature exceeds 150°C (typical), the TSD protection activates and turns off the power devices. They remain off until the die temperature falls below 135°C (typical), at which point the converter restarts.

## APPLICATIONS INFORMATION

The external component selection for the ADP2121 applications circuit is driven by the load requirement and begins with the selection of the inductor. After the inductor is chosen,  $C_{IN}$  and  $C_{OUT}$  can be selected. Components can be identified using the selection guide and recommended selection tables in this section.

### INDUCTOR SELECTION

The high switching frequency of the ADP2121 allows for minimal output voltage ripple, even with small inductors. Inductor sizing is a trade-off between efficiency and transient response. A small inductor leads to a larger inductor current ripple, which provides better transient response but degrades efficiency. Due to the high switching frequency of the ADP2121, multilayer ceramic inductors can be used for an overall smaller solution size. Shielded ferrite core inductors are recommended for their low core losses and low electromagnetic interference (EMI).

As a guideline, the peak-to-peak current ripple of the inductor is typically set to

$$\Delta I_L = 0.45 \times I_{LOAD} \quad (1)$$

where  $I_{LOAD}$  is the maximum output current. The largest ripple current,  $\Delta I_L$ , occurs at the maximum input voltage.

It is important that the inductor be capable of handling the maximum peak inductor current,  $I_{PK}$ , determined by the following equation:

$$I_{PK} = I_{LOAD(MAX)} + \Delta I_L / 2 \quad (2)$$

The dc current rating of the inductor must be greater than the calculated  $I_{PK}$  to prevent core saturation. The ADP2121 is designed for applications with a 0.47  $\mu$ H inductor. Other values are not recommended, and stable operation over all conditions is not guaranteed with their use. Table 6 shows the available 0.47  $\mu$ H surface-mount inductors that have been tested with the ADP2121.

### INPUT CAPACITOR SELECTION

The input capacitor must be able to support the maximum input operating voltage and the maximum rms input current. Select an input capacitor capable of withstanding the rms input current for the maximum load current in the application using the following equation:

$$I_{rms} = I_{OUT(MAX)} \times \frac{\sqrt{V_{OUT} \times (V_{IN} - V_{OUT})}}{V_{IN}} \quad (3)$$

The input capacitor reduces the input voltage ripple caused by the switch currents on the VIN pin. Place the input capacitor as close as possible to the VIN pin.

In principle, different types of capacitors can be considered, but for battery-powered applications, the best choice is the multilayer

ceramic capacitor, due to its small size and low equivalent series resistance (ESR). Table 7 offers suggestions for suitable input capacitors. All capacitors listed in the table are multilayer ceramic capacitors.

It is recommended that the VIN pin be bypassed with a 2.2  $\mu$ F or larger ceramic input capacitor if the supply line has a distributed capacitance of at least 10  $\mu$ F. If not, then at least a 10  $\mu$ F capacitor is recommended on the input supply pin. The input capacitor can be increased without any limit for better input voltage filtering. X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended. Y5U and Z5U dielectrics are not recommended, due to their poor temperature and dc bias characteristics.

### OUTPUT CAPACITOR SELECTION

The output capacitor selection affects both the output voltage ripple and the loop dynamics of the converter. For a given loop crossover frequency (the frequency at which the loop gain drops to 0 dB), the maximum voltage transient excursion (overshoot) is inversely proportional to the value of the output capacitor. The ADP2121 has been designed to operate with small ceramic capacitors in the 4.7  $\mu$ F to 10  $\mu$ F range that have low ESR and equivalent series inductance (ESL). These components are able, therefore, to meet stringent output voltage ripple specifications. X5R or X7R dielectrics with a voltage rating of 6.3 V are recommended. Table 8 shows a list of output MLCC capacitors recommended for ADP2121 applications. The minimum effective capacitance required for stable operation is 1.5  $\mu$ F.

When choosing output capacitors, it is also important to account for the loss of capacitance due to output voltage dc bias. This may result in using a capacitor with a higher rated voltage to achieve the desired capacitance value. Additionally, if ceramic output capacitors are used, the capacitor rms ripple current rating must always meet the application requirements. The rms ripple current is calculated as

$$I_{rms(COUT)} = \frac{1}{2\sqrt{3}} \times \frac{V_{OUT} \times (V_{IN(MAX)} - V_{OUT})}{L \times f_{SW} \times V_{IN(MAX)}} \quad (4)$$

At nominal load currents, the converter operates in pulse frequency mode (PFM), and the overall output voltage ripple is the sum of the voltage spike caused by the output capacitor ESR plus the voltage ripple caused by charging and discharging the output capacitor.

$$\Delta V_{OUT} = \Delta I_L \times (ESR + 1/(8 \times C_{OUT} \times f_{SW})) \quad (5)$$

The largest voltage ripple occurs at the highest input voltage. At light load currents, if MODE is set low, then the converter operates in the power-saving mode (PFM), and the output voltage ripple increases.

Table 6. Recommended Inductor Selection

Manufacturer	Series	Inductance ( $\mu$ H)	DCR ( $m\Omega$ )	Current Rating (mA)	Size (L $\times$ W $\times$ H) (mm)	Package
Murata	LQM2HPNR47MG0L	$0.47 \pm 20\%$	$40 \pm 25\%$	1800	$2.50 \times 2.00 \times 0.90$	1008
	LQM21PNR47MC0D	$0.47 \pm 20\%$	$120 \pm 25\%$	1100	$2.00 \times 1.25 \times 0.50$	0805

## PCB LAYOUT GUIDELINES

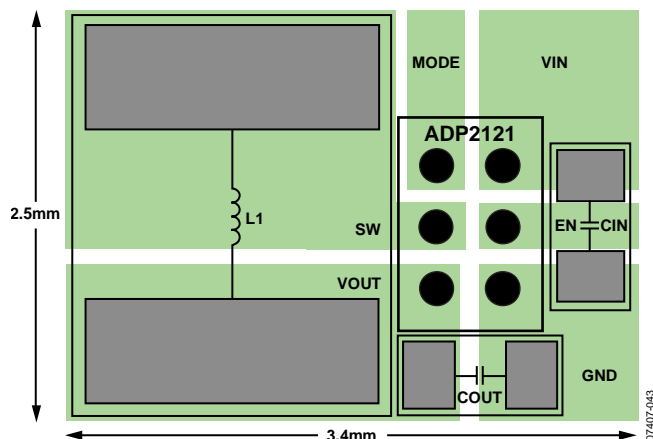

Figure 56. Solution Size with a 1008 Inductor

Figure 57. Solution Size with a 0805 Inductor

Figure 58. Solution Size with a 0603 Inductor

For high efficiency, good regulation, and stability with the ADP2121, a well-designed PCB is required.

Use the following guidelines when designing PCBs:

- Keep the low ESR input capacitor, CIN, close to VIN and GND.
- Keep high current traces as short and as wide as possible.
- Avoid routing high impedance traces near any node connected to SW or near the inductor to prevent radiated noise injection.
- Keep the low ESR output capacitor, COUT, close to FB and GND of the ADP2121. Long trace lengths from the part to the output capacitor add series inductance and may cause instability or increased ripple.
