W320-03

200 MHz Spread Spectrum Clock Synthesizer/Driver with Differential CPU Outputs

Features

- Compliant with Intel® CK-Titan Clock Synthesizer/Driver Specifications
- Multiple output clocks at different frequencies
- Three pairs of differential CPU outputs, up to 200 MHz
- Ten synchronous PCI clocks, three free-running
- Six 3V66 clocks
- Two 48 MHz clocks
- One reference clock at 14.318 MHz
- One VCH clock
- Spread Spectrum clocking (down spread)
- Power-down features (PCI_STOP#, CPU_STOP# PWR_DWN#)
- Three Select inputs (Mode select & IC Frequency Select)
- OE and Test Mode support
- 56-pin SSOP package and 56-pin TSSOP package

Benefits

- Supports next-generation Pentium® processors using differential clock drivers
- Motherboard clock generator
- Support Multiple CPUs and a chipset
- Support for PCI slots and chipset
- Supports AGP, DRCG reference and Hub Link
- Supports USB host controller and graphic controller
- Supports ISA slots and I/O chip
- Enables reduction of electromagnetic interference (EMI) and overall system cost
- Enables ACPI-compliant designs
- Supports up to four CPU clock frequencies
- Enables ATE and “bed of nails” testing
- Widely available, standard package enables lower cost

Notes:
1. TCLK is a test clock driven in on the XTALIN input in test mode.
2. “Normal” mode of operation.
3. Range of reference frequency allowed is min. = 14.316 nominal = 14.31818 MHz, max = 14.32 MHz.
4. Frequency accuracy of 48 MHz must be +167PPM to match USB default.
5. Mid is defined a Voltage level between 1.0V and 1.8V for 3 level input functionality. Low is below 0.8V. High is above 2.0V.
6. TCLK is a test clock over driven on the XTAL_IN input during test mode.
7. Required for DC output impedance verification.
8. These modes are to use the SAME internal dividers as the CPU = 200-MHz mode. The only change is to slow down the internal VCO to allow under clock margining.

Serial Data Interface (SMBus)

To enhance the flexibility and function of the clock synthesizer, a two signal SMBus interface is provided according to the SMBus specification. Through the Serial Data Interface (SDI), various device functions such as individual clock output buffers, etc can be individually enabled or disabled. W320-03 support both block read and block write operations.

The registers associated with the SDI initialize to their default setting upon power-up, and therefore use of this interface is optional. Clock device register changes are normally made upon system initialization, if any are required. The interface can also be used during system operation for power management functions.

Data Protocol

The clock driver serial protocol accepts only block writes from the controller. The bytes must be accessed in sequential order from lowest to highest byte, (most significant bit first) with the ability to stop after any complete byte has been transferred. Indexed bytes are not allowed.

A block write begins with a slave address and a WRITE condition. The R/W bit is used by the SMBus controller as a data direction bit. A zero indicates a WRITE condition to the clock device. The slave receiver address is 11010010 (D2h).

A command code of 0000 0000 (00h) and the byte count bytes are required for any transfer. After the command code, the core logic issues a byte count which describes number of additional bytes required for the transfer, not including the command code and byte count bytes. For example, if the host has 20 data bytes to send, the first byte would be the number 20 (14h), followed by the 20 bytes of data. The byte count byte is required to be a minimum of one byte and a maximum of 32 bytes It may not be 0. *Figure 1* shows an example of a block write.

A transfer is considered valid after the acknowledge bit corresponding to the byte count is read by the controller.

Notes:
10. All parameters specified with loaded outputs.
11. Duty cycle is measured at 1.5V when V_{DD} = 3.3V. When V_{DD} = 2.5V, duty cycle is measured at 1.25V.
12. The 1.0V test load is shown on test circuit page.
13. Determined as a fraction of 2*(Trp – Trn)/(Trp +Trn) Where Trp is a rising edge and Trp is an intersecting falling edge.
14. The 0.7V test load is R_s = 33.2Ω, R_p = 49.9Ω in test circuit.
