

# DRV2625 Ultra Low Power Closed-Loop LRA/ERM Haptic Driver with Built-In Library

## 1 Features

- Ultra Low-Power Shutdown Mode
- Low-Power Standby State
- Resistance-Based Actuator Diagnostics
- SimpleDrive One-Wire Vibration Scheme
- Automatic Resonance Tracking and Reporting
- Automatic Overdrive and Braking
- Automatic Level Calibration
- Drive Compensation Over Battery Discharge
- Configurable Battery Monitor with Power Preservation
- Off-Resonance Driving with Auto-Braking
- LRA Waveform Shape Selection
- Licensed Immersion TouchSense® 2200
- Built-In Library with Loopable Waveform Sequencer
- Real-Time Playback (RTP) Mode
- I<sup>2</sup>C-Controlled Digital Playback Engine
- Hardware and Software Trigger Option
- Automatic Transition to Standby with Auto-Brake
- Optional Interrupt Pin
- 1.8V Compatible, VDD Tolerant Digital Interface <sup>1</sup>

## 2 Applications

- Mobile Phones and Tablets
- Fitness Bands and Wearable Devices
- Remote Controls, Mice, and Peripheral Devices
- Touch-Enabled Devices
- Human-Machine Interfaces

## 3 Description

The DRV2625 device is a haptic driver that relies on a proprietary closed-loop architecture to deliver sharp, strong, and consistent haptic effects while optimizing power consumption.

The internal library and loopable waveform sequencer, together with the automatic overdrive and braking simplifies the process of generating crisp and optimum haptic effects, reducing the burden imposed into the processing unit.

The DRV2625 device features an automatic go-to-standby state and a battery preservation function to help reduce power consumption without user intervention. The NRST pin allows for a full shutdown state for additional power savings.

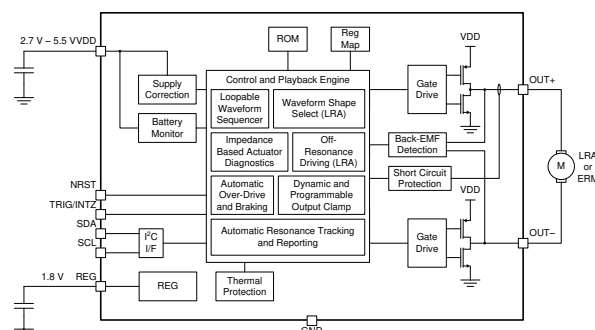

The waveform shape selection allows for sine-wave and square-wave drive to customize the haptic feel as well as the audible performance. Off-resonance driving with automatic braking simplifies the implementation of non-resonant haptic designs.

### Device Information <sup>(1)</sup>

DEVICE NAME	PACKAGE	PACKAGE SIZE (NOM) <sup>(2)</sup>
DRV2625	DSBGA (9)	1.498mm × 1.361mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

(2) The package size (length × width) is a nominal value and includes pins, where applicable.

## 4 Pin Configuration and Functions

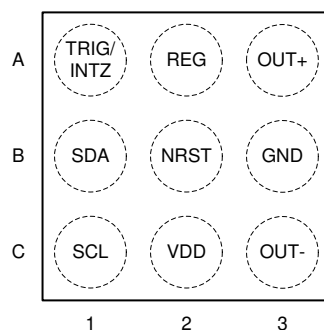

Figure 4-1. YFF Package 9-Pin DSBGA Top View

**Table 4-1. Pin Functions**

PIN		I/O	DESCRIPTION
NAME	NO.		
VDD	C2	P	Supply input (2.7V to 5.5V). A 0.1µF capacitor is required.
GND	B3	P	Supply ground
REG	A2	O	1.8V regulator output. A 0.1µF capacitor is required
OUT-	C3	O	Negative haptic driver differential output
OUT+	A3	O	Positive haptic driver differential output
SDA	B1	I/O	I <sup>2</sup> C data
SCL	C1	I	I <sup>2</sup> C clock
TRIG/INTZ	A1	I/O	Multi-mode pin. Selectable as input trigger (pulse), input enable, or output interrupt. This pin has an internal pull-down. If pin is not used, the pin is connected to ground.
NRST	B2	I	Device reset pin (shutdown mode). If pin is not used, the pin is connected to VDD (no internal pull-up or pull-down).

## 5 Specifications

### 5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) <sup>(1)</sup>

		MIN	MAX	UNIT
Supply Voltage	V <sub>DD</sub>	–0.3	6	V
Input voltage	NRST	–0.3	6	V
	SDA	–0.3	6	V
	SCL	–0.3	6	V
	TRIG/INTZ	–0.3	6	V
Operating free-air temperature range, T <sub>A</sub>		–40	85	°C
Operating junction temperature range, T <sub>J</sub>		–40	150	°C
Storage temperature, T <sub>stg</sub>		–65	150	°C

- (1) Operation outside the *Absolute Maximum Ratings* may cause permanent device damage. *Absolute Maximum Ratings* do not imply functional operation of the device at these or any other conditions beyond those listed under *Recommended Operating Conditions*. If used outside the *Recommended Operating Conditions* but within the *Absolute Maximum Ratings*, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.

### 5.2 ESD Ratings

		MIN	MAX	UNIT
V <sub>(ESD)</sub> Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	–1500	1500	V
	Charged device model (CDM), per JEDEC specification JESD22-C101, all pins <sup>(2)</sup>	–500	500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V <sub>DD</sub>	Supply voltage	2.7		5.5	V
R <sub>L</sub>	Load impedance	8			Ω
C <sub>L</sub>	Load capacitance			100	pF
f <sub>(LRA)</sub>	LRA frequency	45		300	Hz

### 5.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		DRV2625	UNIT
		DSBGA	
		9 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	107	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	0.9	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	18.1	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	3.8	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	18.1	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	—	°C/W

- (1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).

## 5.5 Electrical Characteristics

$T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{DD} = 3.6\text{ V}$  (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
$V_{(REG)}$	Voltage at the REG pin		1.84		V
$I_{IL}$	Digital low-level input current NRST, TRIG/INTZ, SDA, SCL $V_{DD} = 5.5\text{ V}$ , $V_I = 0\text{ V}$			100	nA
$I_{IH}$	SDA, SCL $V_{DD} = 5.5\text{ V}$ , $V_I = V_{DD}$			0.1	$\mu\text{A}$
	NRST $V_{DD} = 5.5\text{ V}$ , $V_I = V_{DD}$			1	
	TRIG/INTZ $V_{DD} = 5.5\text{ V}$ , $V_I = V_{DD}$		2.7	3.5	
$V_{IL}$	Digital low-level input voltage NRST, TRIG/INTZ, SDA, SCL			0.4	V
$V_{IH}$	Digital high-level input voltage NRST, TRIG/INTZ, SDA, SCL	1.41			V
$V_{OL}$	Digital low-level output voltage TRIG/INTZ, SDA 3-mA sink current			0.4	V
$R_{DS(on)}$	Drain-source on-state resistance (LS + HS)		0.75		$\Omega$
$I_{(SD)}$	Shutdown current $V_{(NRST)} = 0\text{ V}$		105	180	nA
$I_{(STBY)}$	Standby current $V_{(NRST)} = V_{DD}$ In stand-by mode		1.55	2	$\mu\text{A}$
$I_{(Q)}$	Quiescent current $V_{(NRST)} = V_{DD}$ In idle mode - no signal		2.5		mA
$Z_{O(SD)}$	Output impedance in shutdown OUT+ to GND, OUT- to GND		15		k $\Omega$
$Z_{O(STBY)}$	Output impedance in standby OUT+ to GND, OUT- to GND		15		k $\Omega$
$Z_{LOAD(th)}$	Load impedance threshold for over-current detection OUT+ to GND, OUT- to GND		4		$\Omega$

## 5.6 Timing Requirements

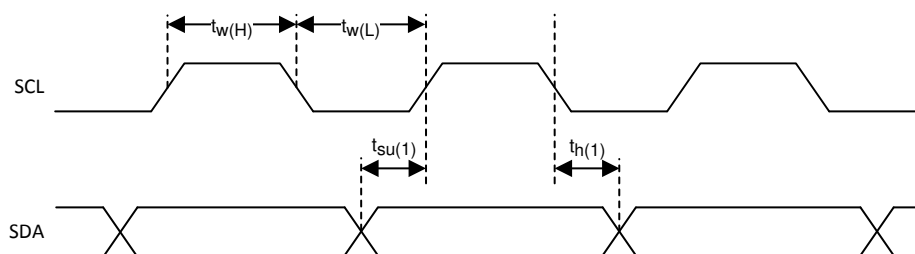

$T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{DD} = 3.6\text{ V}$  (unless otherwise noted)

	MIN	NOM	MAX	UNIT
$f_{(SCL)}$			400	kHz
$t_{w(H)}$	0.6			$\mu\text{s}$
$t_{w(L)}$	1.3			$\mu\text{s}$
$t_{su(1)}$	100			ns
$t_{h(1)}$	10			ns
$t_{(BUF)}$	1.3			$\mu\text{s}$
$t_{su(2)}$	0.6			$\mu\text{s}$
$t_{h(2)}$	0.6			$\mu\text{s}$
$t_{su(3)}$	0.6			$\mu\text{s}$

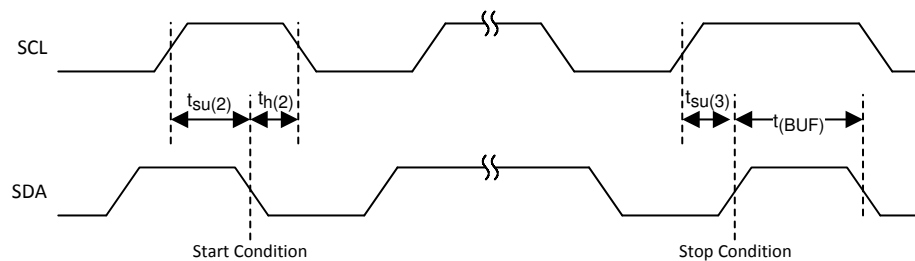

## 5.7 Switching Characteristics

$T_A = 25\text{ }^{\circ}\text{C}$ ,  $V_{DD} = 3.6\text{ V}$  (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
$t_{(on)}$	Device startup time from shutdown standby		1		ms
$t_{(start)}$	Waveform startup time from trigger to output signal		1		ms
$f_{O(PWM)}$	PWM output frequency (in OUT+ and OUT-)		20.5		kHz

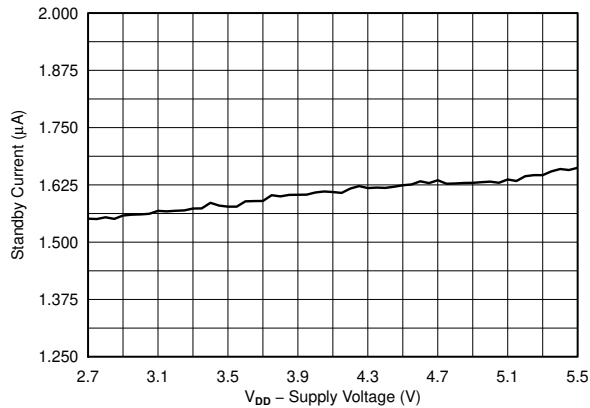

**Figure 5-1. SCL and SDA Timing**

ERM Click (Open-Loop) with Automatic Braking** $V_{DD} = 3.6\text{ V}$ **Figure 5-13. LRA SimpleDrive with Closed-Loop** $V_{DD} = 3.6\text{ V}$ **Figure 5-14. LRA SimpleDrive with Sinewave**

## 6 Parameter Measurement Information

### 6.1 Test Setup for Graphs

To capture the graphs displayed in the [Typical Characteristics](#) section, the following first-order RC-filter setup is used with the exception of the waveform in [Figure 6-1](#) which is captured without any output filter. The filter is used when viewing output signals on an oscilloscope because output PWM modulation is present in all modes. Maintain that effective impedance of the filter is not too low because the closed-loop and auto resonance-tracking features can be affected. Therefore, TI recommends that this exact filter be used for output measurement. Most oscilloscopes have an input impedance of  $1\text{M}\Omega$  on each channel and therefore have an approximately 1% loss in measured amplitude because of the voltage-divider effect with the filter.

**Figure 6-1. Test Setup**

#### 6.1.1 Default Test Conditions

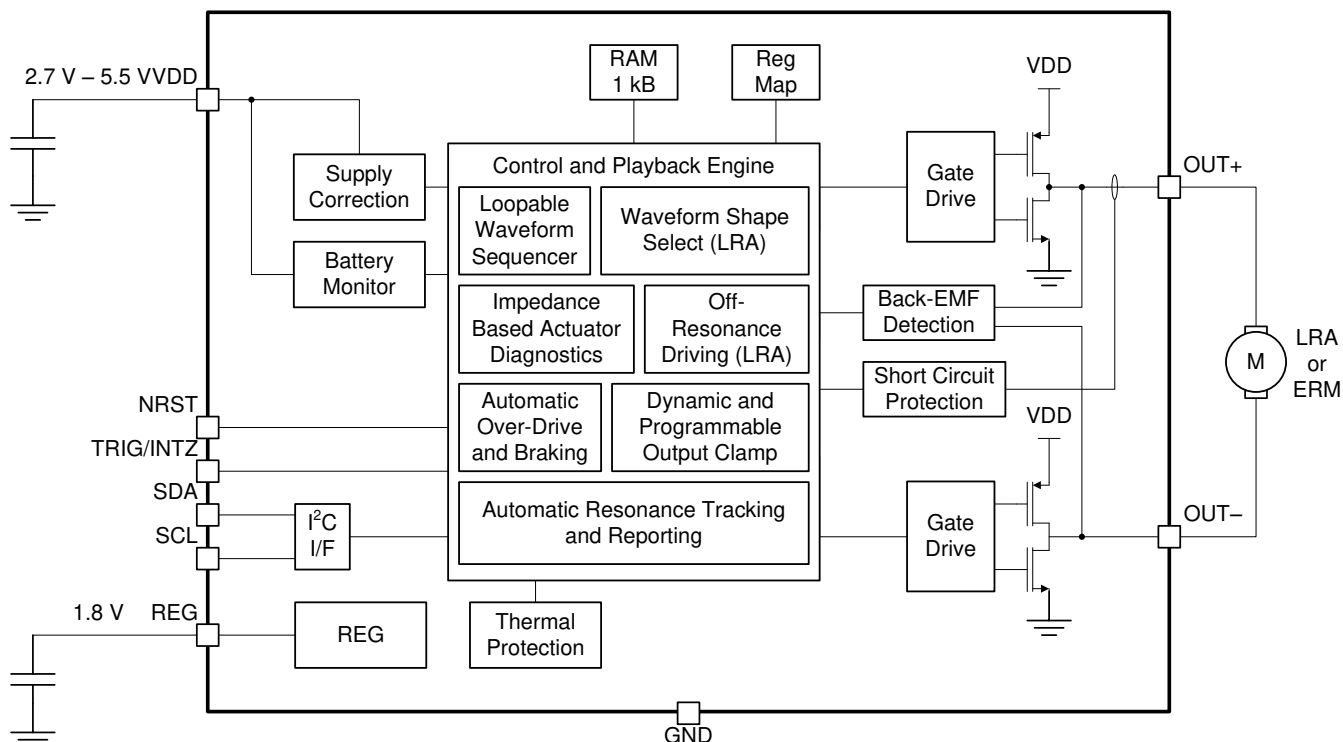

- $V_{DD} = 3.6\text{ V}$ , unless otherwise noted.
- Real actuators (as opposed to modeled actuators) were used as loads for both ERM and LRA modes unless otherwise noted.

## 7 Detailed Description

### 7.1 Overview

The DRV2625 device is a haptic driver that relies on a proprietary closed-loop architecture to deliver sharp, strong, and consistent haptic effects while optimizing power consumption. The internal library and loopable waveform sequencer, the automatic overdrive, and the braking simplifies the process of generating crisp and optimum haptic effects, reducing the burden imposed into the processing unit. The DRV2625 device has an automatic go-to-standby state and a battery preservation function to help reduce power consumption without user intervention. The NRST pin allows for a full shutdown state for additional power savings. The waveform shape selection allows for sine-wave and square-wave drive to customize the haptic feel as well as the audible performance. Off-resonance driving with automatic braking simplifies the implementation of non-resonant haptic designs.

### 7.2 Functional Block Diagram

### 7.3 Feature Description

#### 7.3.1 Support for ERM and LRA Actuators

The DRV2625 device supports both ERM and LRA actuators. The LRA\_ERM bit must be configured to select the type of actuator that the device uses.

#### 7.3.2 Smart-Loop Architecture

The smart-loop architecture is an advanced closed-loop system that optimizes the performance of the actuator and allows for failure detection. The architecture consists of automatic resonance tracking and reporting (for an LRA), automatic level calibration, accelerated startup and braking, resistance based diagnostics routines, and other proprietary algorithms.

##### 7.3.2.1 Auto-Resonance Engine for LRA

The DRV2625 auto-resonance engine tracks the resonant frequency of an LRA in real time, effectively locking onto the resonance frequency after half of a cycle. If the resonant frequency shifts in the middle of a waveform for any reason, the engine tracks the frequency from cycle to cycle. The auto-resonance engine accomplishes

tracking by constantly monitoring the back-EMF of the actuator. Note that the auto-resonance engine is not affected by the auto calibration process, which is only used for level calibration. No calibration is required for the auto resonance engine.

### 7.3.2.2 Real-Time Resonance-Frequency Reporting for LRA

The smart-loop architecture makes the resonant frequency of the LRA available through I<sup>2</sup>C. Because frequency reporting occurs in real time, the frequency recording must be polled while the DRV2625 device synchronizes with the LRA. The polled data is not polled when the actuator is idle or braking.

### 7.3.2.3 Automatic Switch to Open-Loop for LRA

In the event that an LRA produces a non-valid back-EMF signal, the DRV2625 device automatically switches to open-loop operation and continues to deliver energy to the actuator in overdrive mode at a default and configurable frequency. If the LRA begins to produce a valid back-EMF signal, the auto-resonance engine automatically takes control and continues to track the resonant frequency in real time. When synchronized, this mode uses all of the benefits of the smart-loop architecture.

$$f_{(LRA\_NO-BEMF)} \approx \frac{1}{2 \times (t_{(DRIVE\_TIME[4:0])} - t_{(ZC\_DET\_TIME[1:0])})} \quad (1)$$

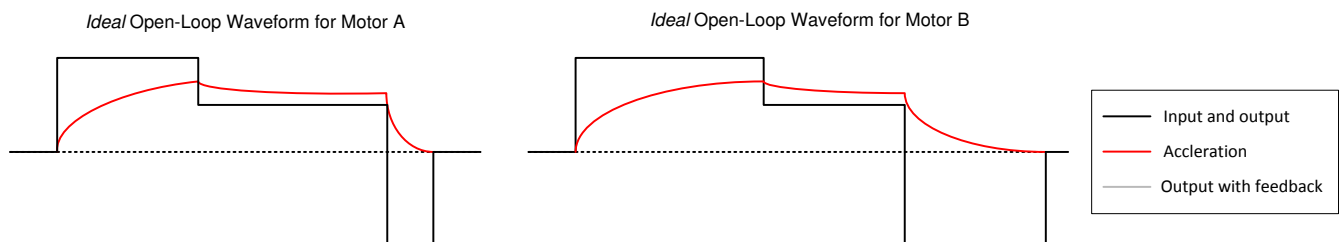

The DRV2625 device offers an automatic transition to open-loop mode without the re-synchronization option. This feature is enabled by setting the LRA\_AUTO\_OPEN\_LOOP bit. The transition to open-loop mode only occurs when the driver fails to synchronize with the LRA. The AUTO\_OL\_CNT[1:0] parameter can be adjusted to set the amount of non-synchronized cycles allowed before the transition to the open-loop mode. Note that the open-loop mode does not receive benefits from the smart-loop architecture, such as automatic overdrive and braking.

$$f_{(LRA\_OL)} = \frac{1}{OL\_LRA\_PERIOD[6:0] \times 97.56 \times 10^{-6}} \quad (2)$$

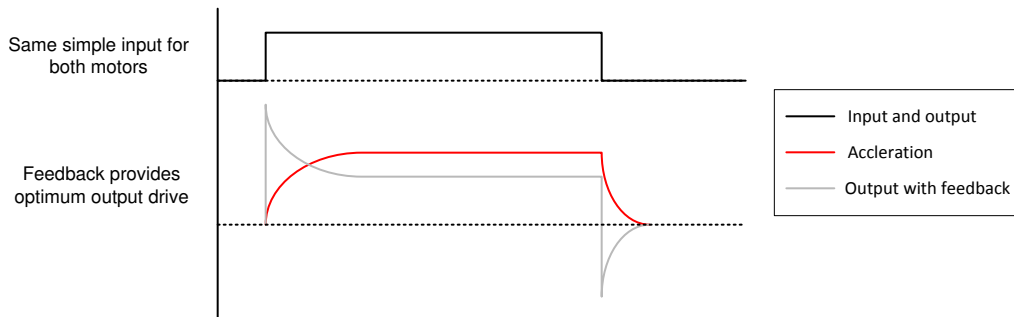

### 7.3.2.4 Automatic Overdrive and Braking

A key feature of the DRV2625 is the smart-loop architecture which employs actuator feedback control for both ERMs and LRAs. The feedback control desensitizes the input waveform from the motor-response behavior by providing automatic overdrive and automatic braking.

An open-loop haptic system typically drives an overdrive voltage at startup that is higher than the steady-state rated voltage of the actuator to decrease the startup latency of the actuator. Likewise, a braking algorithm must be employed for effective braking. When using an open-loop driver, these behaviors must be contained in the input waveform data. Consider the example of an ERM actuator of Motor A and another of Motor B. The input waveform in open loop is different (see [Figure 7-1](#)). In contrast, by using the smart-loop technology with automatic overdrive and braking, the same input waveform works for both actuators (see [Figure 7-2](#)). The smart-loop architecture works equally well for LRAs with a combination of feedback control and an auto-resonance engine.

**Figure 7-1. Typical Open Loop Waveform**

**Figure 7-2. Waveform Simplification With Smart Loop**

#### 7.3.2.4.1 Startup Boost

To reduce the actuator start-time performance, the DRV2625 device has an overdrive boost feature that applies higher loop gain to transient response of the actuator.

#### 7.3.2.4.2 Brake Factor

To optimize the actuator brake-time performance, the DRV2625 device provides a means to increase the gain ratio between braking and driving gain. Higher feedback-gain ratios reduce the brake time, however, these ratios also reduce the stability of the closed-loop system. The FB\_BRAKE\_FACTOR parameter can be adjusted to set the brake factor.

#### 7.3.2.5 Automatic Level Calibration

The smart-loop architecture uses actuator feedback by monitoring the back-EMF behavior of the actuator. The level of back-EMF voltage can vary across actuator manufacturers because of the specific actuator construction. Auto calibration compensates for this variation and also performs scaling for the desired actuator according to the specified rated voltage and overdrive clamp-register settings. When auto calibration is performed, a 100% signal level at any of the DRV2625 input interfaces supplies the rated voltage to the actuator at steady-state. The feedback allows the output level to increase above the rated voltage level for automatic overdrive and braking, but the output level does not exceed the programmable overdrive clamp voltage.

##### 7.3.2.5.1 Automatic Compensation for Resistive Losses

The DRV2625 device automatically compensates for resistive losses in the driver. During the automatic level-calibration routine, the resistance of the actuator is checked and the compensation factor is determined and stored in the A\_CAL\_COMP parameter.

##### 7.3.2.5.2 Automatic Back-EMF Normalization

The DRV2625 device automatically compensates for differences in back-EMF magnitude between actuators. The compensation factor is determined during the automatic level-calibration routine and the factor is stored in the A\_CAL\_BEMF parameter.

##### 7.3.2.5.3 Calibration Time Adjustment

The duration of the automatic level-calibration routine has an impact on accuracy. The impact is highly dependent on the start-time characteristic of the actuator. The auto-calibration routine expects the actuator to have reached a steady acceleration before the calibration factors are calculated. Because the start-time characteristic can be different for each actuator, the AUTO\_CAL\_TIME parameter can change the duration of the automatic level-calibration routine to optimize calibration performance. Alternatively, the duration of the calibration routine can be adjusted by the trigger by selecting the option in the AUTO\_CAL\_TIME parameter.

##### 7.3.2.5.4 Loop-Gain Control

The DRV2625 device allows the user to control how fast the driver attempts to match the back-EMF (and thus motor velocity) and the input signal level. Higher loop-gain (or faster settling) options result in less-stable operation than lower loop gain (or slower settling). The LOOP\_GAIN parameter controls the loop gain.

#### 7.3.2.5.5 Back-EMF Gain Control

The BEMF\_GAIN parameter sets the analog gain for the back-EMF amplifier. The auto-calibration routine automatically populates the BEMF\_GAIN bit with the most appropriate value for the actuator.

Modifying the SAMPLE\_TIME parameter also adjusts the back-EMF gain. The higher the sample time the higher the gain.

#### 7.3.2.6 Actuator Diagnostics

The DRV2625 device is capable of determining whether the actuator is not present (open) or shorted. If a fault is detected during the diagnostic process, the DIAG\_RESULT bit is asserted.

The DRV2625 device also features actuator resistance measurement, which is available in the DIAG\_Z\_RESULT parameter.

$$R_{(act)} = 478.43 \cdot \frac{DIAG\_Z\_RESULT[7:0]}{719 + 4 \cdot CURRENT\_K[7:0]} \quad (3)$$

#### 7.3.2.7 Automatic Re-Synchronization

For LRA actuators, the DRV2625 device features automatic re-synchronization, which automatically pushes the actuator in the correct direction when a waveform begins playing while the actuator is moving. If the actuator is at rest when the waveform begins, the DRV2625 device drives in the default direction.

### 7.3.3 Open-Loop Operation

In the event that open-loop operation is desired the DRV2625 device includes an open-loop drive mode that overrides any close-loop parameter and is available through the digital interface.

When activated, the digital open-loop mode is available for pre-stored waveforms as well as for RTP mode.

The dynamic range for open-loop operation is set by the OD\_CLAMP[7:0], which sets the maximum peak value. Amplitude codes (either through RTP or internal memory) scales the output accordingly.

For LRA actuators, the OL\_LRA\_PERIOD parameter programs the operating frequency, which is derived from the PWM output frequency,  $f_{O(PWM)}$ .

#### 7.3.3.1 Waveform Shape Selection for LRA

The DRV2625 offers a selection of either sine-wave or square-wave waveform shape in open-loop mode. The WAVE\_SHAPE\_LRA parameter selects which shape to use. The WAVE\_SHAPE\_LRA parameter is ignored in ERM mode and in closed-loop mode.

#### 7.3.3.2 Automatic Braking in Open Loop

The DRV2625 offers automatic braking in open-loop for both ERM and LRA. To accomplish automatic braking, the DRV2625 switches to close-loop during the braking period, therefore resorting to the close-loop waveform shape. The AUTO\_BRK\_OL parameter can be used to enable or disable the automatic braking feature. To use the automatic braking feature, the device must be configured appropriately for closed-loop operation.

### 7.3.4 Flexible Front-End Interface

The DRV2625 device offers multiple ways to launch and control haptic effects. The MODE parameter selects from either using the waveform sequencer (and hence trigger the waveforms with either an internal or external trigger), or by using RTP mode. Additional flexibility is provided by the multi-purpose TRIG/INTZ pin, which can be configured with the TRIG\_PIN\_FUNC parameter.

#### 7.3.4.1 Internal Memory Interface

The DRV2625 device has two internal-ROM libraries designed by Immersion called TS2200. The first library works in closed-loop mode, and is designed for LRA actuators. The second library is specifically tuned for ERMs operated in open-loop mode. If additional adjustments are required to the library effect to optimize performance

of a particular actuator model, the library parametrization parameters (ODT, SPT, SNT and BRT) can be used for fine tuning. The library selection is done by the LIB\_SEL bit.

**Table 7-1. Library Table**

LIBRARY	ACTUATOR	RATED VOLTAGE	OVERDRIVE VOLTAGE	RISE TIME	BRAKE TIME
A	LRA Closed-Loop	TBD	TBD	AUTO	AUTO
B	ERM Open-Loop	1.3V	3V	40ms to 60ms	20ms to 40ms

Using the internal library has several advantages including:

- Offloading processing requirements, such as digital streaming (RTP).
- Improving latency by only requiring a trigger signal.
- Reducing I<sup>2</sup>C traffic by eliminating the requirement to transfer waveform data

#### 7.3.4.1.1 Library Parameterization

The waveforms stored in the internal library are augmented by the time offset parameters. This augmentation occurs only for the waveforms stored in the internal library and not for RTP mode. The purpose of this functionality is to add *time stretching* (or time shrinking) to the waveform. This functionality is useful for customizing the entire library of waveforms for a specific actuator rise time and fall time.

The time parameters that can be stretched or shrunk include:

<b>ODT</b>	Overdrive time
<b>SPT</b>	Sustain positive time
<b>SNT</b>	Sustain Negative Time
<b>BRT</b>	Brake Time

The time values are additive offsets and are 8-bit signed values. The default offset of these values is 0. Positive values add and negative values subtract from the *time* value of the effect that is currently played. The most positive value in the waveform is automatically interpreted as the overdrive time, and the most negative value in the waveform is automatically interpreted as the brake time. These time-offset parameters are applied to both voltage-time pairs and linear ramps. For linear ramps, linear interpolation is stretched (or shrunk) over the two operative points for the period.

$$t_{\text{(final)}} = t_{\text{(orig)}} + t_{\text{(ofs)}} \quad (4)$$

#### 7.3.4.1.2 Playback Interval

The internal memory ticks are by default interpreted as 5-ms intervals. If additional granularity is desired, then a 1-ms interval can be selected by using the PLAYBACK\_INTERVAL bit.

#### 7.3.4.1.3 Waveform Sequencer

The waveform sequencer queues waveform identifiers for playback. Eight sequence registers queue up to eight waveforms for sequential playback. A waveform identifier is an integer value referring to the index position of a waveform in the internal library. Once the user has selected the Waveform Playback as the process to run in the MODE[1:0] parameter, playback begins at WAV\_FRM\_SEQ1 when the user triggers the process (either with the GO bit or externally, if configured to do so). When playback of that waveform ends, the waveform sequencer plays the waveform identifier held in WAV\_FRM\_SEQ2 if the next waveform is non-zero. The waveform sequencer continues in this way until the sequencer reaches an identifier value of zero or until all eight identifiers are played, whichever scenario is reached first.

The waveform identifier range is 1 to 127. The MSB of each sequence register can implement a delay between sequence waveforms. When the MSB is high, bits [6:0] indicate the length of the wait time. The wait time for that step then becomes WAV\_FRM\_SEQ[6:0] × 10ms.

The DRV2625 allows for looping each waveform a number of times before moving onto the next waveform identifier. The waveform-looping functionality can be configured by the WAV\_SEQ\_LOOP parameters.

The DRV2625 also allows for looping the entire waveform sequencer by configuring the WAV\_SEQ\_MAIN parameter. In this case, the waveform sequencer loops all valid WAV\_FRM\_SEQn identifiers according to the number specified in the WAV\_SEQ\_MAIN. For example, if the first and second identifiers are valid (for example 1 and 2), the third identifier is 0 (signaling to stop), and the WAV\_SEQ\_MAIN is configured to loop once (play the waveform sequence twice), then the DRV2625 device plays waveform 1, then waveform 2, then waveform 1 then waveform 2, and then go to standby.

#### 7.3.4.2 Real-Time Playback (RTP) Interface

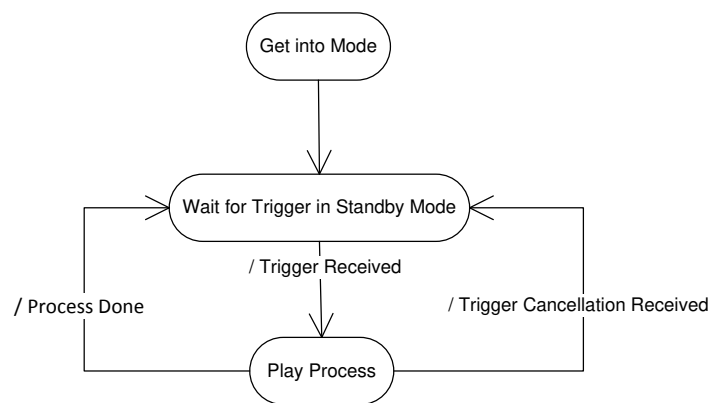

The real-time playback mode is a simple, single 8-bit register interface that holds an amplitude value. When real-time playback is enabled, the RTP\_INPUT parameter, which represents an amplitude value, is sent directly to the playback engine. Once triggered, the value is played until the user sends a stop trigger or removes the device from RTP mode. The RTP mode is a digital streaming mode where the user enters a register value over the I<sup>2</sup>C. Because of the similarity between RTP mode and legacy PWM modes, any API (application-programming interface) designed for use with a PWM generator in the host processor can write the data values over the I<sup>2</sup>C rather than writing the data values to the host timer. This ability frees a timer in the host while retaining compatibility with the original software.

For the LRA, the DRV2625 device automatically tracks the resonance frequency unless the CONTROL\_LOOP bit is set to open loop operation. If the CONTROL\_LOOP bit is set to open loop, the LRA is driven according to the open-loop frequency set in the OL\_LRA\_PERIOD parameter.

#### 7.3.4.3 Process Trigger

All processes (RTP, Waveform Sequencer, Calibration and Diagnostics) in the DRV2625 device are triggered processes, which means that the user has to trigger the process before the process begins. A trigger can be achieved by software using the GO bit, or by hardware using the TRIG/INTZ pin. The process stops once completed, or if a stop trigger is sent. For information on external trigger functionality refer to [Section 7.3.16](#).

A typical process (either RTP, Waveform Sequencer, Calibration or Diagnostics) starts and end following the diagram in [Figure 7-3](#).

**Figure 7-3. Typical Process Execution**

#### 7.3.5 Noise Gate Control

The DRV2625 device features a noise gate that filters out any voltage smaller than a particular threshold to prevent unintended vibrations. The NG\_THRESH bit controls the threshold.

#### 7.3.6 Edge Rate Control

The DRV2625 output driver implements edge rate control (ERC). This control maintains that the rise and fall characteristics of the output drivers do not emit levels of radiation that can interfere with other circuitry common

in mobile and portable platforms. Because of ERC most system do not require external output filters, capacitors, or ferrite beads.

### 7.3.7 Constant Vibration Strength

The DRV2625 device features power-supply feedback. If the supply voltage drifts over time (because of battery discharge, for example), the vibration strength remains the same as long as enough supply voltage is available to sustain the required output voltage.

### 7.3.8 Battery Voltage Reporting

During playback, the DRV2625 device provides cycle-by-cycle voltage measurement of the  $V_{DD}$  pin. The VBAT[7:0] parameter provides this information. Use Equation 5 to calculate the voltage based on VBAT[7:0].

$$\text{Voltage Level (V)} = \frac{\text{VBAT}[7:0]}{255} \times 5.6 \quad (5)$$

### 7.3.9 Ultra Low-Power Shutdown

Setting the device into shutdown state by using the NRST pin reduces the power consumption to sub-micro levels, allowing the system to preserve power when haptics are not required. In this state, register content is not preserved.

### 7.3.10 Automatic Go-To-Stand-by (Low Power)

The DRV2625 automatically goes into a low power standby state when not in use. In this state, register content is preserved and I<sup>2</sup>C communication is available. The DRV2625 features a fast turn-on time from standby when requested to play a waveform. The following note covers corner cases where DRV2625 does not fully return to the standby state and get stuck in a pseudo-standby state. Use an additional I2C transaction to clear the pseudo-standby state and fully return to standby mode.

#### Note

This case applies when using the following settings: AUTO\_BRK\_INT0\_STBY = 1 (enabled), TRIG\_PIN\_FUNC = 2 (internal trigger mode using I2C), and MODE = 0 or 1 (RTP or waveform sequencer mode). When the RTP mode is stopped by writing the GO bit to 0, the device completes the auto-brake time period and return to a pseudo-standby state. When a waveform is stopped by writing the GO bit to 0 before the end of the programmed waveform duration, the device completes the auto-brake time period and return to a pseudo-standby state. This pseudo-standby state consumes additional current than the standby state. In both cases for RTP or waveform sequencer mode, an additional I2C write or read to any register after the auto-braking time clears the pseudo-standby state. The auto-brake time is (PLAYBACK\_INTERVAL\*10); add 1ms. Use a 1ms buffer to insure the auto-brake time period is completed.

### 7.3.11 I<sup>2</sup>C Watchdog Timer

If an I<sup>2</sup>C stops unexpectedly, the possibility exists for the I<sup>2</sup>C protocol to remain in a *hanged* state. To allow for the recovery of the communication without having to power cycle the device, the DRV2625 device includes an automatic watchdog timer that resets the I<sup>2</sup>C protocol without user intervention after 4.33 ms.

### 7.3.12 Device Protection

The DRV2625 device has integrated protection circuits for thermal and over-current protection, as well as for UVLO. When such conditions are present, the DRV2625 device immediately stops playback and go into the standby state. The respective status bit is set in register 0x01, which is cleared upon register read. An interrupt can be fired if the DRV2625 device is configured to do so.

If the critical condition disappears (the over-current condition goes away), the DRV2625 device proceeds with normal operation, but because the status bits are sticky, the bits continue to be asserted until the status register is read.

#### 7.3.12.1 Thermal Sensor

The DRV2625 has a thermal circuit that immediately puts the device in standby state and sets the OVER\_TEMP bit in the event of an over-temperature condition.

If the interrupt functionality is selected in the TRIG\_PIN\_FUNC parameter and the interrupt is not masked, and interrupt are fired to alert the host processor of a critical condition.

#### 7.3.12.2 Over-Current Protection

During waveform playback, if the impedance at the output pin of the DRV2625 device is too low, the DRV2625 device immediately goes into standby state and latches the over-current flag (OC\_DETECT bit).

If the interrupt functionality is selected in the TRIG\_PIN\_FUNC parameter and the interrupt is not masked, an interrupt is fired to alert the host processor of a critical condition.

#### 7.3.12.3 VDD UVLO Protection

The DRV2625 device has a battery monitor that monitors the VDD level to maintain that the levels is above a configurable threshold (using UVLO\_THRES[2:0] parameter).

In the event of a VDD droop, the DRV2625 device immediately goes into standby state to reduce current consumption and latches the UVLO flag (UVLO bit).

If the interrupt functionality is selected in the TRIG\_PIN\_FUNC parameter and the interrupt is not masked, and interrupt is fired to alert the host processor of a critical condition.

#### 7.3.12.4 Brownout Protection

The DRV2625 device has on-chip brownout protection. When activated, a reset signal is issued that returns the DRV2625 device to the initial default state. If the regulator voltage  $V_{(REG)}$  goes below the brownout protection threshold ( $V_{(BOT)}$ ) the DRV2625 device automatically shuts down. When  $V_{(REG)}$  returns to the typical output voltage (1.8 V) the DRV2625 device returns to the initial device state. The brownout protection threshold ( $V_{(BOT)}$ ) is typically at 1.6 V.

#### 7.3.13 POR

The POR circuit is designed to enable the device only when both VDD and REG voltages are at a healthy level. If REG voltage level dips below the reset threshold, the device automatically aborts any process and shutdown until appropriate power levels are available, once a valid voltage is present in both VDD and REG nodes, the device proceeds with the power-up sequence and return to the default state. If VDD drops below UVLO with VREG still at a healthy level, the device immediately goes into standby state.

#### 7.3.14 Silicon Revision Control

The DRV2625 has a revision control implemented in CHIPID[3:0] and REV[3:0] parameter (located in register 0x00). This feature allows an external controller to determine which device is connected to the external controller and select the appropriate firmware to control the device, which makes firmware development easier to port from one platform to another.

#### 7.3.15 Support for LRA and ERM Actuators

The DRV2625 device supports both LRA and ERM actuators. The default state is LRA mode, but can be changed by using the LRA\_ERM bit.

#### 7.3.16 Multi-Purpose Pin Functionality

To enhance the flexibility of the DRV2625, the TRIG/INTZ pin is a configurable, multi-purpose pin that takes different functionality depending on the mode of operation. The pin can serve as an input trigger-pulse pin, as an input trigger-level (enable) pin and as an output interrupt pin. Note that the TRIG/INTZ pin can only execute one function at a time (either trigger-edge, trigger-level (enable) or interrupt function), therefore if a particular function is selected (for example, TRIG/INTZ configured as input trigger-edge), then the other functionality is not available (for example, interrupt).

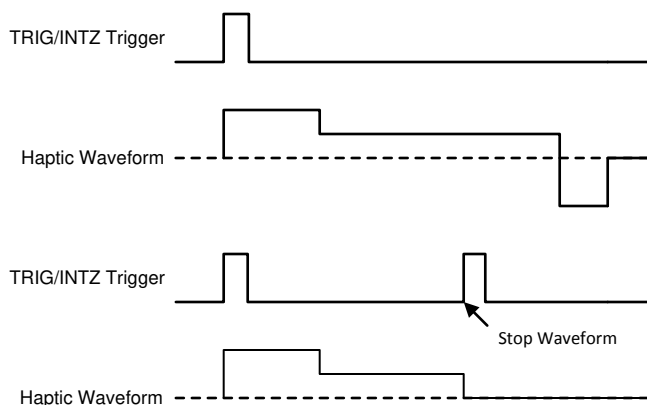

### 7.3.16.1 Trigger-Pulse Functionality

The trigger-pulse functionality allows for an external processor to initiate the process (either waveform sequencer, RTP, diagnostics or calibration) by pulsing the TRIG/INTZ pin. The process initiates and play until the process is done, at which point the device goes back into standby mode to preserve power. If a stop trigger (another trigger-pulse) is received before the routine has finished, the routine stops and the device goes back into standby state. In the case of diagnostics mode, a stop trigger causes the diagnostic routine to abort and no result is reported. In the case of automatic level calibration routine, a stop trigger causes the calibration to abort unless the AUTO\_CAL\_TIME[2:0] is set to trigger control, in which case the stop trigger is required for the calibration to complete, and the calibration gracefully finishes and provide the expected output. Also note that a stop trigger can also be achieved by writing 0 to the GO bit.

The minimum pulse width duration is 1 $\mu$ s and the typical pulse is kept short. If the pulse is too long, a corner case in the following note can occur.

#### Note

This case applies when using the following settings: AUTO\_BRK\_INT0\_STBY = 1 (enabled), TRIG\_PIN\_FUNC = 0 (external pulse trigger), and MODE = 1 (waveform sequencer mode). If the TRIG pin is not returned low within the auto-brake period, then the subsequent high signals on TRIG can be missed. Meaning the TRIG high signal can not play the waveform sequence. The auto-brake time is (PLAYBACK\_INTERVAL\*10).

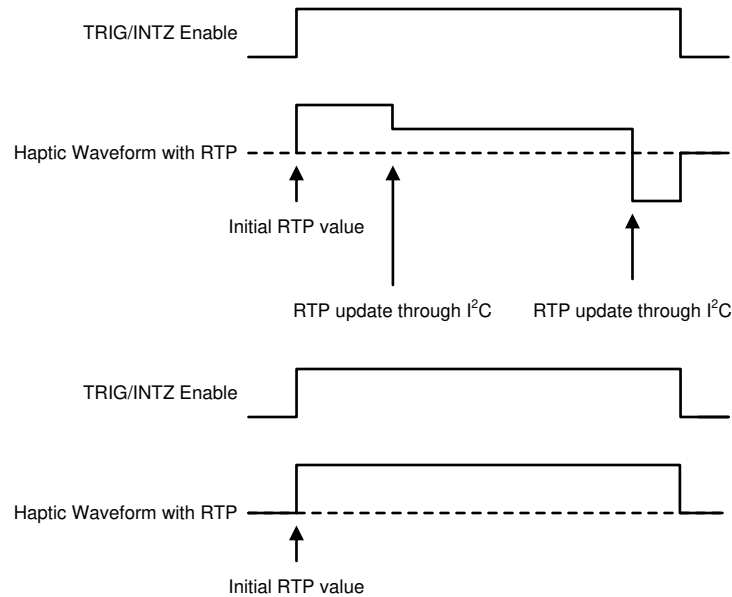

**Figure 7-4. TRIG/INTZ Functionality in Trigger-Pulse Mode**

### 7.3.16.2 Trigger-Level (Enable) Functionality

The trigger-level (enable) functionality allows for an external micro-controller to wake up the DRV2625 by asserting the TRIG/INTZ pin (high), which immediately starts playing the process (either waveform sequencer, RTP value, diagnostics or auto-calibration). Once the TRIG/INTZ pin de-asserts (low) the device goes back to standby state to preserve power. If braking is desired before going into standby state, the AUTO\_BRK\_INT0\_STBY bit can be set to allow automatic braking. Please see the below note on using the automatic braking into standby function. Note that automatic braking is ignored during calibration.

#### Note

This case applies when using the following settings: AUTO\_BRK\_INT0\_STBY = 1 (enabled), TRIG\_PIN\_FUNC = 1 (external level trigger), and MODE = 1 (waveform sequencer mode). If the TRIG pin is not returned low within the auto-brake period, then the subsequent high signals on TRIG can be missed. Meaning the TRIG high signal does not play the waveform sequence. The auto-brake time is (PLAYBACK\_INTERVAL\*10).

**Figure 7-5. TRIG/INTZ Functionality in Trigger-Level (Enable) Mode**

### 7.3.16.3 Interrupt Functionality

The interrupt functionality allows for the DRV2625 to communicate to an external processor that a particular condition has occurred. When configured as an interrupt, the TRIG/INTZ pin becomes an output in open-drain configuration. An external pull-up is required for this mode. When asserted, the TRIG/INTZ pin pulls down the node until the interrupt is cleared (which is done by a reading the status register). All interrupts are maskable. Please see the note below for low-power applications. A description of the supported interrupts is as follows:

#### Note

TI does not recommend to pull TRIG/INTZ high in low-power applications when trying to detect interrupts. The pull-up can cause an extra approximately 500µA of current to be consumed from VDD. Use the I2C status register for monitoring interrupts.

OC\_DETECT is flagged if an over-current event happens in the output stage during a process execution (such as waveform playback or auto-calibration).

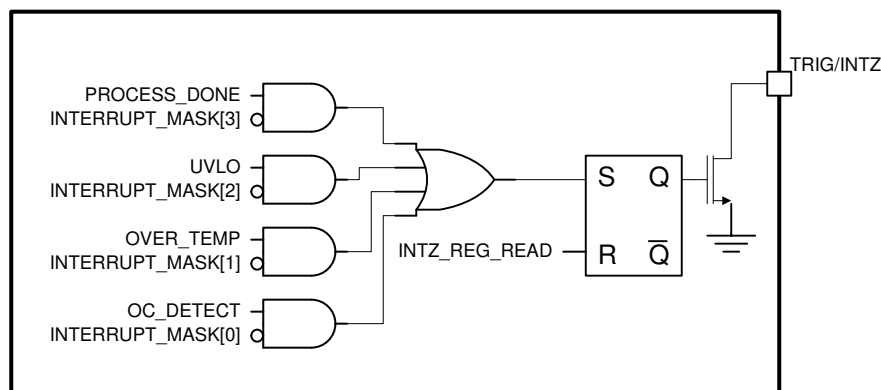

OVER\_TEMP is flagged if the junction temperature goes above the thermal threshold during a process execution (such as waveform playback, diagnostics or auto-calibration).

UVLO is flagged if VDD drops below the VDD\_THRES voltage during a process execution (such as waveform playback, diagnostics or auto-calibration).

PROCESS\_DONE is flagged when the process (waveform sequencer, diagnostics or calibration) finishes. The PROCESS\_DONE bit does not assert if the process is interrupted (such as with a stop trigger or by a critical condition). Note that RTP will never cause the PROCESS\_DONE to assert because RTP never finishes on its own. See the note for specific waveforms returning PROCESS\_DONE.

#### Note

With AUTO\_BRK\_INTX\_STBY = 1, the PROCESS\_DONE trigger can repeat multiple times when playing multi-click or multi-patterned waveforms. TI does not recommend to use the PROCESS\_DONE functionality with the auto-brake into standby bit enabled.

**Figure 7-6. TRIG/INTZ Functionality in Interrupt Mode**

Critical conditions, such as UVLO, over-temperature or over-current is not monitored while the device is in standby state. However, UVLO and over-temperature conditions is monitored during I<sup>2</sup>C communication is ongoing, even if the device is in standby state.

#### 7.3.17 Automatic Transition to Standby State

The DRV2625 allows for automatic transition to standby state to preserve power. If the device goes into standby and a new waveform is triggered, the DRV2625 wakes-up and immediately play the requested waveform.

#### 7.3.18 Automatic Brake into Standby

The DRV2625 allows for automatic braking before going into standby. If the AUTO\_BRK\_INTX\_STBY is asserted, the device brakes the actuator (if necessary) before going into standby. This functionality is bypassed in the event of a critical condition, such as over-temperature, over-current, UVLO, and NRST assertion.

#### 7.3.19 Battery Monitoring and Power Preservation

The DRV2625 device continuously monitors the VDD voltage. In the event of a VDD voltage glitch that goes below the UVLO\_THRES[2:0] voltage, the DRV2625 immediately stops any playback and goes into standby state. The UVLO status bit asserts and, if configured, the TRIG/INTZ pin is asserted. Note that going into standby due to a VDD glitch bypasses any braking, even if AUTO\_BRK\_INTX\_STBY is enabled. I<sup>2</sup>C communication is not interrupted if a UVLO condition happens. However, because a UVLO condition can potentially corrupt such communication, TI recommends checking the UVLO flag after I<sup>2</sup>C transactions as a way to verify that the content was not corrupted in the process.

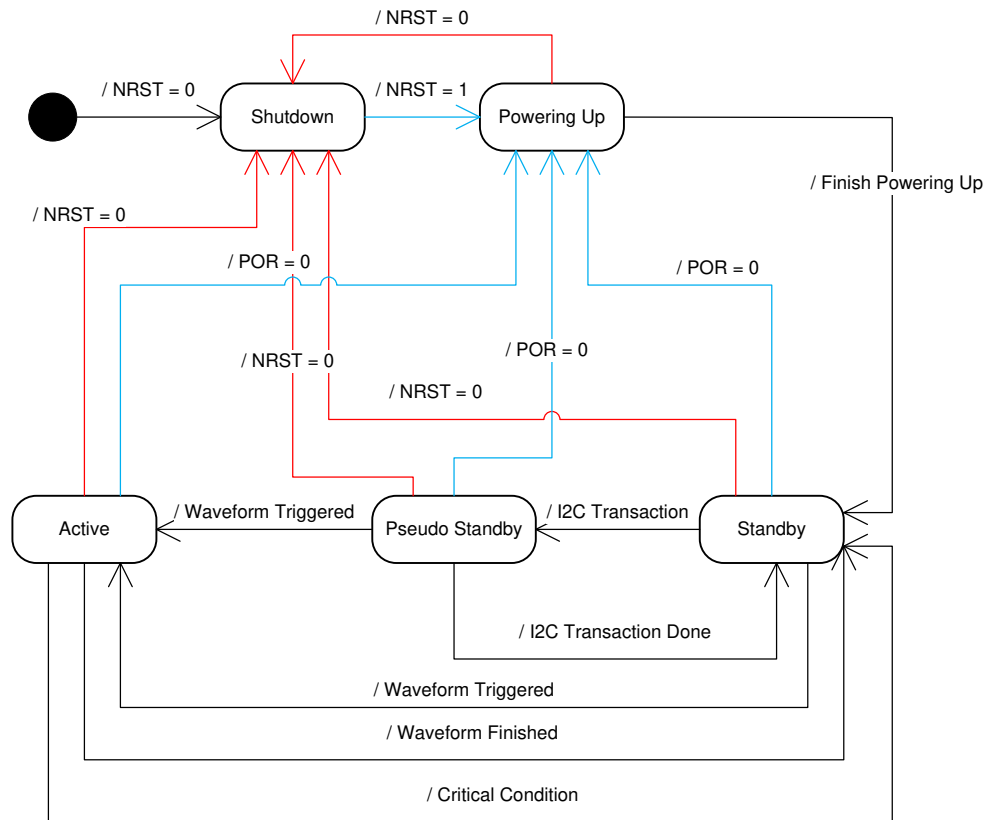

The DRV2625 also features a battery preservation mode that monitors the battery, and if VDD voltage drops below a specified threshold (see BAT\_LIFE\_EXT\_LVL1[7:0] and BAT\_LIFE\_EXT\_LVL2[7:0] parameters) automatically clamps the maximum output voltage, as specified by the user (see OD\_CLAMP\_LVL1[7:0] and OD\_CLAMP\_LVL2[7:0] parameters).

### 7.4 Device Functional Modes

#### 7.4.1 Power States

The DRV2625 device has multiple power states to optimize power consumption. In the event of a critical condition, the DRV2625 device goes immediately into the standby state. [Figure 7-7](#) shows the transitions into and out of each state.

For specific corner cases, the DRV2625 can get stuck in the pseudo-standby state and not fully return to the low-power standby state. Reference the note in [Automatic Go-To-Stand-by \(Low Power\)](#). To exit this pseudo-standby state, a simple I<sup>2</sup>C transaction can be used. The logic for clearing the pseudo-standby state follows the I<sup>2</sup>C Transaction Done path in [Figure 7-7](#).

**Figure 7-7. Power State Diagram**

#### 7.4.2 Operation With $V_{DD} < 2.5\text{ V}$ (Minimum $V_{DD}$ )

Operating the device with a  $V_{DD}$  value below 2.5 V is not recommended.

#### 7.4.3 Operation With $V_{DD} > 6\text{ V}$ (Absolute Maximum $V_{DD}$ )

The DRV2625 device is designed to operate at up to 5.5 V with an absolute maximum voltage of 6 V. If exposed to voltages above 6 V, the device can suffer permanent damage.

#### 7.4.4 Operation in Shutdown State

The NRST pin of the DRV2625 device gates the power-up of the device. When NRST is asserted (logic low), all internal blocks of the device (including I<sup>2</sup>C controller) are off to achieve ultra low power.

When the NRST pin is deasserted (logic high), the DRV2625 device powers-up, loads all the default conditions and goes into standby state to preserve power.

Asserting the NRST pin has an immediate effect. Any process being executed is aborted immediately and the device goes into shutdown state.

The DRV2625 device allows for the NRST to be permanently tied directly to V<sub>DD</sub>, in which case the shutdown state is bypassed.

#### 7.4.5 Operation in STANDBY State

The DRV2625 is optimized for power preservation, therefore the device automatically goes into standby when not in use.

In standby state, I<sup>2</sup>C communication is available and register content is preserved.

Stand-by state turns-off all non-essential blocks to preserve power, but features a fast turn on time that allows for low latency haptic playback from this mode.

If the host controller wants to force the DRV2625 device into standby, the host controller can do so by sending a stop trigger, which can be done by writing a 0 to the GO bit, or, if using an external trigger, by following the appropriate mechanism as described in [Section 7.3.4.3](#).

The DRV2625 features an automatic braking option that makes the drive brake the actuator before going into standby state. The automatic braking feature is executed every time the device goes into standby state, with the exception of a critical condition (such as over-current, thermal shutdown or UVLO). The automatic braking feature can be enabled or disabled by using the AUTO\_BRK\_INT0\_STBY bit.

#### 7.4.6 Operation in ACTIVE State

The DRV2625 goes into active mode only when the device must run a process (either waveform playback, calibration or diagnostics).

When the device gets into active mode, the first thing done is to check for critical conditions (such as over-current, thermal shutdown or UVLO). If a critical condition is present, the DRV2625 device sets the appropriate flag (and fires an interrupt if configured to do so), and immediately goes into standby. If no critical condition is present, the DRV2625 device runs the routine and when finished returns to the standby state.

If a critical condition happens during a routine execution, the routine is aborted immediately and the device sets the appropriate flag (and fires an interrupt if configured to do so), and immediately goes into standby.

If a stop trigger is received while a routine is being executed, the routine is stopped and the device goes into standby state. If the automatic braking option is enabled (AUTO\_BRK\_INT0\_STBY bit), then the DRV2625 device brakes the actuator before going into standby state.

#### 7.4.7 Changing Modes of Operation

The DRV2625 device has 8 parameters that control different aspects of modes of operation, namely: LRA\_ERM, MODE[1:0], CONTROL\_LOOP, TRIG\_PIN\_FUNC, AUTO\_BRK\_INT0\_STBY, AUTO\_BRK\_OL, and LRA\_WAVE\_SHAPE. If any of these parameters are changed in the middle of a process execution (waveform playback, diagnostics or calibration), the DRV2625 interprets the change as an abort and goes into standby.

LRA\_ERM parameter selects the actuator type.

MODE[1:0] selects between the 4 available process that can be run, namely RTP and Waveform Sequencer for waveform playback, diagnostics and calibration. The DRV2625 device is in standby state until a trigger is received. At that point the device executes the process selected in the MODE[1:0] parameter. Once finished, the DRV2625 device returns into standby state.

CONTROL\_LOOP selects between open loop and closed loop.

TRIG\_PIN\_FUNC parameter selects the functionality of the TRIG/INTZ pin among the 3 possibilities: pulse trigger, level trigger and interrupt.

AUTO\_BRK\_INT0\_STBY parameter enables automatic braking when going into standby. The DRV2625 device monitors the back-EMF of the actuator before going into standby, and if the back-EMF is moving, the actuator brakes and then go into standby. Note that for this function to be executed in open loop, the AUTO\_BRK\_OL pin must be enabled.

AUTO\_BRK\_OL parameter enables automatic braking for open loop mode. If enabled, every time a waveform is configured with a negative amplitude, the DRV2625 device brakes the actuator. This feature assumes that the actuator has been calibrated and works under closed-loop conditions.

LRA\_WAVE\_SHAPE parameter (available for LRA only) allows for selecting the waveform shape to be used when driving the LRA in open loop. In closed-loop this parameter is ignored.

### 7.5 Operation During Exceptional Conditions

This section lists different exceptional conditions and the ways that the DRV2625 device operates during these conditions. This section also describes how the device goes into and out of these states.

### **7.5.1 Operation With No Actuator Attached**

In open loop mode, the DRV2625 device drives the waveform as intended by the user.

In LRA closed-loop mode, if a waveform is played without an actuator connected to the OUT+ and OUT– pins, the output pins toggle. However, the toggling frequency is not predictable.

In ERM closed-loop mode, the output pins attempts to drive, however the amplitude is not predictable.

### **7.5.2 Operation With a Non-Moving Actuator Attached**

In the ERM case, the DRV2625 device attempts to overdrive the actuator until movement is detected.

The model of a non-moving actuator can be simplified as a resistor. If a resistor (with similar loading as an LRA, such as 25Ω) is connected across the OUT+ and OUT– pins, and the DRV2625 device is in LRA closed-loop mode, the output pins toggle at a default f. In LRA open-loop mode the output pins toggle at the specified open-loop frequency.

### **7.5.3 Operation With a Short at REG Pin**

If the REG pin is shorted to GND, the device turns off. When the short is removed, the device starts in the default condition.

### **7.5.4 Operation With a Short at OUT+, OUT–, or Both**

During playback, if any of the output pins (OUT+ or OUT–) is shorted to  $V_{DD}$ , GND, or to each other, a current-protection circuit automatically enables to shut-down the output stage, the OC\_DETECT bit is asserted (and an interrupt is fired if enabled) and the DRV2625 device goes into standby state.

The DRV2625 device only checks for shorts when running a process (either RTP, waveform sequencer, diagnostics or calibration). If the short occurs when the device is idle, the short is not detected until the device attempts to run a process.

## 7.6 Programming

### 7.6.1 Auto-Resonance Engine Programming for the LRA

#### 7.6.1.1 Drive-Time Programming

The resonance frequency of each LRA actuator varies based on many factors and is generally dominated by mechanical properties. The auto-resonance engine-tracking system is optimized by providing information about the resonance frequency of the actuator. The DRIVE\_TIME[4:0] bit is used as an initial guess for the half-period of the LRA. The drive time is automatically and quickly adjusted for optimum drive. For example, if the LRA has a resonance frequency of 200Hz, then the drive time is set to 2.5ms.

For ERM actuators, the DRIVE\_TIME[4:0] bit controls the rate for back-EMF sampling. Lower drive times imply higher back-EMF sampling frequencies which cause higher peak-to-average ratios in the output signal, and requires more supply headroom. Higher drive times imply lower back-EMF sampling frequencies which cause the feedback to react at a slower rate.

#### 7.6.1.2 Current-Dissipation Time Programming

To sense the back-EMF of the actuator, the DRV2625 device goes into high impedance mode. However, before the device enters this mode, the device must dissipate the current in the actuator. The DRV2625 device controls the time allocated for dissipation-current through the IDISS\_TIME[3:0] parameter.

#### 7.6.1.3 Blanking Time Programming

After the current in the actuator dissipates, the DRV2625 device waits for a blanking time of the signal to settle before the back-EMF analog-to-digital (AD) conversion converts. The BLANKING\_TIME[3:0] parameter controls this time.

#### 7.6.1.4 Zero-Crossing Detect-Time Programming

When the blanking time expires, the back-EMF AD monitors for zero crossings. The ZC\_DET\_TIME[1:0] parameter controls the minimum time allowed for detecting zero crossings.

### 7.6.2 Automatic-Level Calibration Programming

#### 7.6.2.1 Rated Voltage Programming

The rated voltage is the driving voltage that the driver outputs during steady state. However, in closed-loop drive mode, temporarily having an output voltage that is higher than the rated voltage is possible.

The RATED\_VOLTAGE[7:0] parameter sets the rated voltage for the closed-loop drive modes.

$$V_{(ERM-CL\_AV)} = 21.88 \times 10^{-3} \text{ RATED\_VOLTAGE}[7:0] \quad (6)$$

$$V_{(LRA-CL\_RMS)} = \frac{20.58 \times 10^{-3} \times \text{RATED\_VOLTAGE}[7:0]}{\sqrt{1 - (4 \times t_{(SAMPLE\_TIME)} + 300 \times 10^{-6}) \times f_{(LRA)}}} \quad (7)$$

In open-loop mode, the RATED\_VOLTAGE[7:0] parameter is ignored. Instead, the OD\_CLAMP[7:0] parameter is used to set the full-scale voltage for the open-loop drive modes.

$$V_{(ERM-OL\_AV)} = 21.59 \times 10^{-3} \text{ OD\_CLAMP}[7:0] \quad (8)$$

$$V_{(LRA-OL\_RMS)} = 21.32 \times 10^{-3} \times \text{OD\_CLAMP}[7:0] \times \sqrt{1 - f_{(LRA)} \times 800 \times 10^{-6}} \quad (9)$$

The auto-calibration routine uses the RATED\_VOLTAGE[7:0] and OD\_CLAMP[7:0] bits as inputs and therefore these registers must be written before calibration is performed. Any modification of this register value is followed by calibration to appropriately set A\_CAL\_BEMF[7:0].

### 7.6.2.2 Overdrive Voltage-Clamp Programming

During closed-loop operation, the actuator feedback allows the output voltage to go above the rated voltage during the automatic overdrive and automatic braking periods. The OD\_CLAMP[7:0] parameter sets a clamp so that the automatic overdrive is bounded. The OD\_CLAMP[7:0] parameter also serves as the full-scale reference voltage for open-loop operation. The OD\_CLAMP[7:0] parameter always represents the maximum *peak voltage* that is allowed, regardless of the mode.

#### Note

If the supply voltage ( $V_{DD}$ ) is less than the overdrive clamp voltage, the output driver is unable to reach the clamp voltage value because the output voltage cannot exceed the supply voltage. If the rated voltage exceeds the overdrive clamp voltage, the overdrive clamp voltage has priority over the rated voltage.

$$V_{(ERM\_clamp)} = \frac{21.64 \times 10^{-3} \times OD\_CLAMP[7:0] \times (t_{(DRIVE\_TIME)} - 300 \times 10^{-6})}{t_{(DRIVE\_TIME)} + t_{(IDISS\_TIME)} + t_{(BLANKING\_TIME)}} \quad (10)$$

$$V_{(LRA\_clamp)} = 21.22 \times 10^{-3} \times OD\_CLAMP[7:0] \quad (11)$$

### 7.6.3 I<sup>2</sup>C Interface

#### 7.6.3.1 TI Haptic Broadcast Mode

The DRV2625 device has a TI haptic broadcast mode where, if enabled using the I<sup>2</sup>C\_BCAST\_EN bit, makes the device respond to the peripheral address 0x58 (7-bit) or 1011000 in binary. This mode is useful in the event that multiple haptic drivers implementing the TI haptic broadcast mode as installed in the system. In such a scenario, writing the GO bit to the 0x58 peripheral address causes all haptic drivers to trigger the process at the same time.

#### 7.6.3.2 I<sup>2</sup>C Communication Availability

The I<sup>2</sup>C protocol is available for read/write operations during Standby, and Active states.

#### 7.6.3.3 General I<sup>2</sup>C Operation

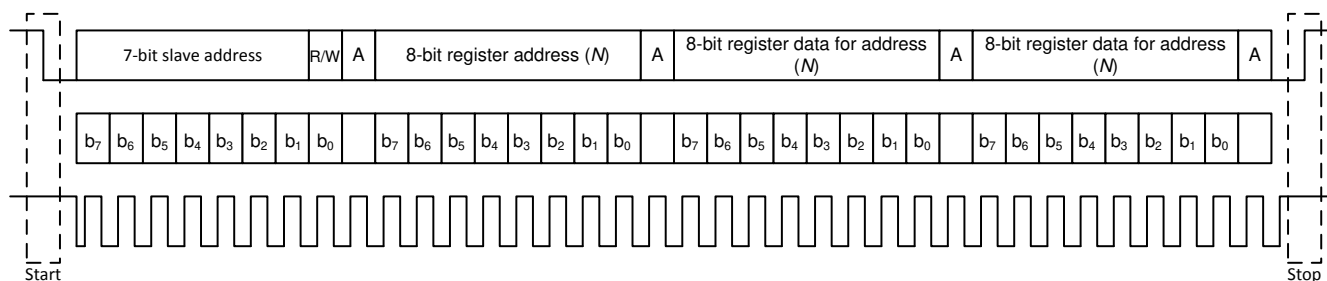

The I<sup>2</sup>C bus employs two signals, SDA (data) and SCL (clock), to communicate between integrated circuits in a system. The bus transfers data serially, one bit at a time. The 8-bit address and data bytes are transferred with the most-significant bit (MSB) first. In addition, each byte transferred on the bus is acknowledged by the receiving device with an acknowledge bit. Each transfer operation begins with the controller device driving a start condition on the bus and ends with the controller device driving a stop condition on the bus. The bus uses transitions on the data pin (SDA) while the clock is at logic high to indicate start and stop conditions. A high-to-low transition on the SDA signal indicates a start, and a low-to-high transition indicates a stop. Normal data-bit transitions must occur within the low time of the clock period. [Figure 7-8](#) shows a typical sequence. The controller device generates the 7-bit peripheral address and the read-write (R/W) bit to start communication with a peripheral device. The controller device then waits for an acknowledge condition. The peripheral device holds the SDA signal low during the acknowledge clock period to indicate acknowledgment. When the acknowledgment occurs, the controller transmits the next byte of the sequence. Each device is addressed by a unique 7-bit peripheral address plus a R/W bit (1 byte). All compatible devices share the same signals through a bidirectional bus using a wired-AND connection.

The number of bytes that can be transmitted between start and stop conditions is not limited. When the last word transfers, the controller generates a stop condition to release the bus. [Figure 7-8](#) shows a generic data-transfer sequence.

Use external pull-up resistors for the SDA and SCL signals to set the logic-high level for the bus. Pull-up resistors between 660 Ω and 4.7kΩ are recommended. Do not allow the SDA and SCL voltages to exceed the DRV2625 supply voltage,  $V_{DD}$ .

**Note**

The DRV2625 peripheral address is 0x5A (7-bit), or 1011010 in binary.

**Figure 7-8. Typical I<sup>2</sup>C Sequence**

The DRV2625 device operates as an I<sup>2</sup>C-peripheral 1.8V logic thresholds, but can operate up to the  $V_{DD}$  voltage. The device address is 0x5A (7-bit), or 1011010 in binary which is equivalent to 0xB4 (8-bit) for writing and 0xB5 (8-bit) for reading.

**7.6.3.4 Single-Byte and Multiple-Byte Transfers**

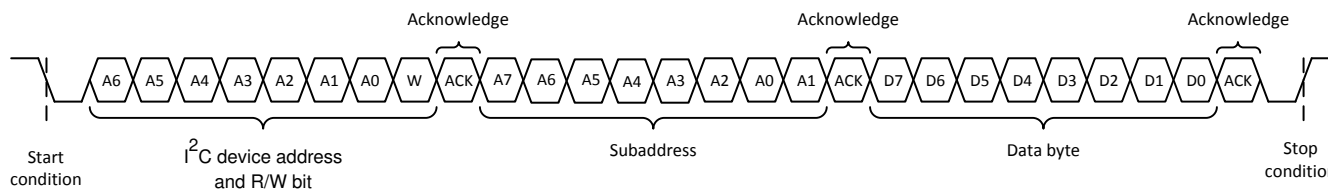

The serial control interface supports both single-byte and multiple-byte R/W operations for all registers.

During multiple-byte read operations, the DRV2625 device responds with data one byte at a time and beginning at the signed register. The device responds as long as the master device continues to respond with acknowledges.

The DRV2625 supports sequential I<sup>2</sup>C addressing. For write transactions, a sequential I<sup>2</sup>C write transaction has taken place if a register is issued followed by data for that register as well as the remaining registers that follow. For I<sup>2</sup>C sequential-write transactions, the register issued then serves as the starting point and the amount of data transmitted subsequently before a stop or start is transmitted determines how many registers are written.

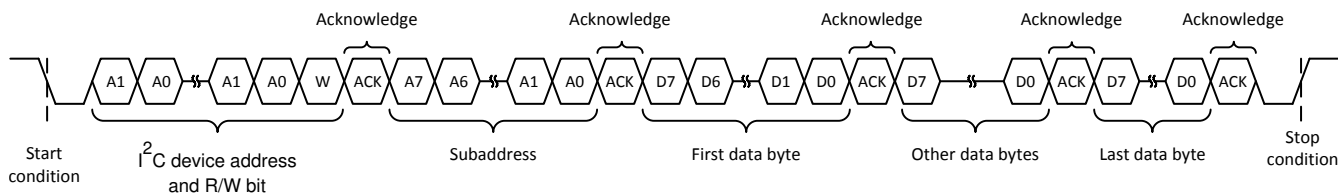

**7.6.3.5 Single-Byte Write**

As shown in Figure 7-9, a single-byte data-write transfer begins with the controller device transmitting a start condition followed by the I<sup>2</sup>C device address and the read-write bit. The read-write bit determines the direction of the data transfer. For a write-data transfer, the read-write bit must be set to 0. After receiving the correct I<sup>2</sup>C device address and the read-write bit, the DRV2625 responds with an acknowledge bit. Next, the controller transmits the register byte corresponding to the DRV2625 internal-memory address that is accessed. After receiving the register byte, the device responds again with an acknowledge bit. Finally, the controller device transmits a stop condition to complete the single-byte data-write transfer.

**Figure 7-9. Single-Byte Write Transfer**

### 7.6.3.6 Multiple-Byte Write and Incremental Multiple-Byte Write

A multiple-byte data write transfer is identical to a single-byte data write transfer except that multiple data bytes are transmitted by the controller device to the DRV2625 device as shown in Figure 7-10. After receiving each data byte, the DRV2625 device responds with an acknowledge bit.

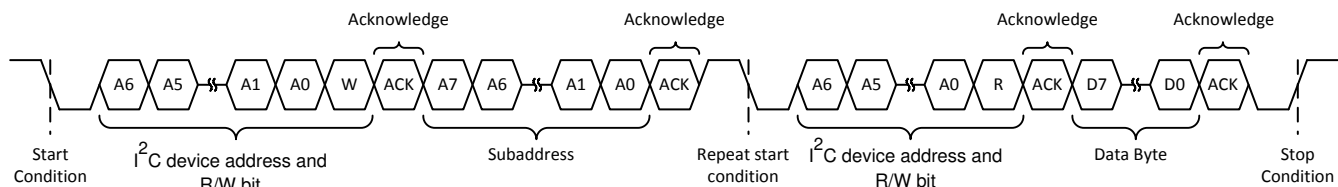

**Figure 7-10. Multiple-Byte Write Transfer**

### 7.6.3.7 Single-Byte Read

Figure 7-11 shows that a single-byte data-read transfer begins with the controller device transmitting a start condition followed by the I<sup>2</sup>C device address and the read-write bit. For the data-read transfer, both a write followed by a read actually occur. Initially, a write occurs to transfer the address byte of the internal memory address to be read. As a result, the read-write bit is set to 0.

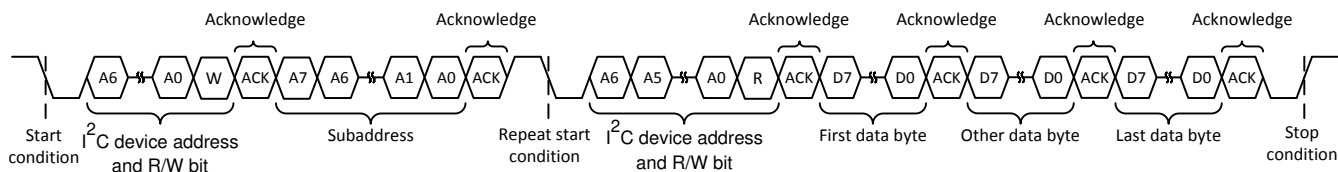

After receiving the DRV2625 address and the read-write bit, the DRV2625 device responds with an acknowledge bit. The controller then sends the internal memory address byte, after which the device issues an acknowledge bit. The controller device transmits another start condition followed by the DRV2625 address and the read-write bit again. On this occasion, the read-write bit is set to 1, indicating a read transfer. Next, the DRV2625 device transmits the data byte from the memory address that is read. After receiving the data byte, the controller device transmits a not-acknowledge followed by a stop condition to complete the single-byte data read transfer. See the note in the Section 7.6.3.3 section.

**Figure 7-11. Single-Byte Read Transfer**

### 7.6.3.8 Multiple-Byte Read

A multiple-byte data-read transfer is identical to a single-byte data-read transfer except that multiple data bytes are transmitted by the DRV2625 device to the controller device as shown in Figure 7-12. With the exception of the last data byte, the controller device responds with an acknowledge bit after receiving each data byte.

**Figure 7-12. Multiple-Byte Read Transfer**

### 7.6.4 Programming for Open-Loop Operation

The DRV2625 device can be used in open-loop mode and closed-loop mode. If open-loop operation is desired, the first step is to determine which actuator type is to use, either ERM or LRA.

#### 7.6.4.1 Programming for ERM Open-Loop Operation

To configure the DRV2625 device in ERM open-loop operation, the ERM must be selected by writing the LRA\_ERM bit to 0, and the CONTROL\_LOOP bit to 1.

#### 7.6.4.2 Programming for LRA Open-Loop Operation

To configure the DRV2625 device in LRA open-loop operation, the LRA must be selected by writing the LRA\_ERM bit to 1, and the CONTROL\_LOOP bit to 1. Additionally, the OL\_LRA\_PERIOD parameter must be configured with the appropriate LRA frequency.

### 7.6.5 Programming for Closed-Loop Operation

For closed-loop operation, the device must be calibrated according to the actuator selection. When calibrated accordingly, the user is only required to provide the desired waveform. The DRV2625 device automatically adjusts the level and, for the LRA, automatically adjusts the driving frequency.

### 7.6.6 Diagnostics Routine

The DRV2625 has a diagnostic routine that can be selected by the MODE[1:0] parameter. The purpose of the routine is to determine if the actuator can be safely and correctly driven. If a problem is detected by the diagnostic routine, the DIAG\_RESULT bit asserts (high). After running the diagnostic routine, the DIAG\_RESULT is checked to assess the result of the diagnostic routine. If the diagnostic routine does not finish due to a critical condition, such as a UVLO, over temperature or over-current condition, the diagnostic routine is aborted and the DIAG\_RESULT is set to 1.

The diagnostic routine is composed of 2 sub-routines: a resistance measurement routine and a functional routine.

The resistance measurement sub-routine reports the resistance of the actuator as seen from the differential output pins (OUT+ and OUT-) and placed on the DIAG\_Z\_RESULT parameter. The resistance measurement sub-routine is always executed during the diagnostics routine and the output is reported in the DIAG\_Z\_RESULT. The only exception is during an over-temperature or UVLO condition, in which case the diagnostic routine aborts immediately and the device goes into standby state.

---

#### Note

An over-current condition never happens in this sub-routine, even in the presence of a short, because the resistance measurement injects a small current that is not detected by the over-current detection circuit. The resistance measurement sub-routine is the first to be executed. Also, this sub-routine does not cause the DIAG\_RESULT bit to assert.

---

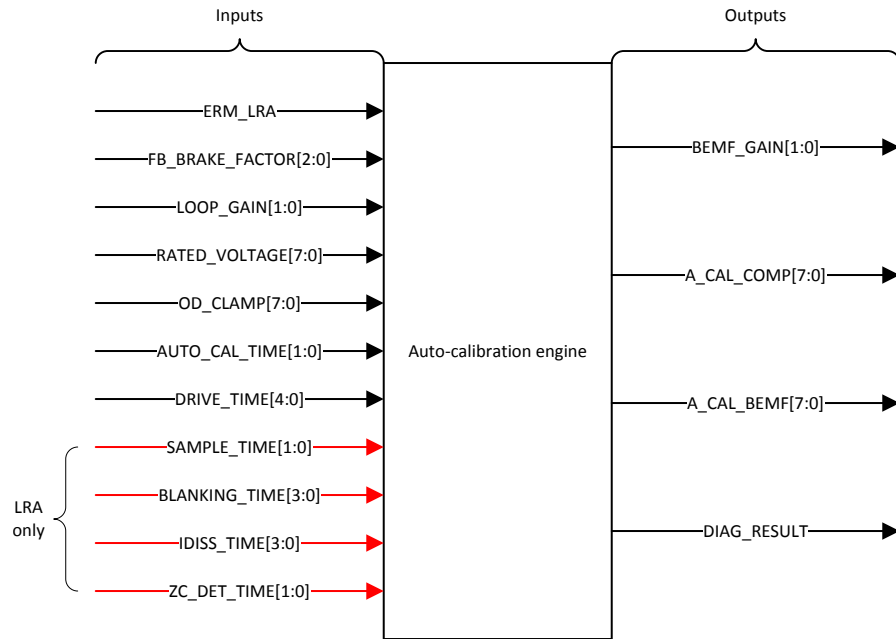

After the resistance measurement, the diagnostic routine plays a diagnostic waveform to determine whether the actuator can be successfully driven. A short or open condition, as well as failure to detect a valid BEMF causes the DIAG\_RESULT bit to assert. Note that if a critical problem is experienced during the diagnostic routine, such as an over-current condition, the routine can be aborted, and the DIAG\_RESULT asserts.

### 7.6.7 Calibration Routine

The DRV2625 has a calibration routine that automatically populates all critical parameters required for successfully driving a specific actuator (the one connected and being calibrated) in closed-loop. Variation occurs between different actuators even if the actuators are of the same model. To maintain desired results, TI recommends that the calibration routine be run at least once for each actuator.

The calibration engine requires a number of parameters as inputs before the calibration can be executed. When the inputs are configured, the calibration routine can be executed. After calibration execution occurs, the output parameters are written over the specified register locations. [Figure 7-13](#) shows all of the required inputs and

generated outputs. To maintain proper auto-resonance operation, the LRA actuator type requires more input parameters than the ERM. The LRA parameters are ignored when the device is in ERM mode.

**Figure 7-13. Calibration-Engine Functional Diagram**

For proper calibration results, the calibration waveform must be executed long enough to achieve a steady acceleration. Therefore, the DRV2625 device has a configurable amount of time for the calibration waveform, which can be selected by the AUTO\_CAL\_TIME[1:0] parameter. Additionally, the option to control the calibration time by using a trigger is provided to accommodate for the cases that require longer times than those allowed by the AUTO\_CAL\_TIME parameter. Under the triggered control option, the calibration starts executing after the initial trigger, and then stops execution once a stop trigger is received. At that point the output values of the calibration is populated. Note that a minimum duration is required for the calibration to work properly.

**Table 7-2. Calibration Routine Behavior Under Different AUTO\_CAL\_TIME Selections**

AUTO_CAL_TIME[1:0]	ACTION	COMMENTS
0	250ms calibration waveform	
1	500ms calibration waveform	
2	1s calibration waveform	
3	Trigger controlled	Can be triggered either using the GO bit or externally. To use the external trigger, the TRIG_PIN_FUNC parameter must be configured appropriately. In this case the minimum duration is 1s, otherwise the result of the calibration can be corrupted.

The following instructions list the step-by-step register configuration for auto-calibration.

1. Apply a valid supply voltage to the DRV2625 device, and then pull the NRST pin high. The supply voltage allows for adequate drive voltage of the selected actuator.
2. Write a value of 0x03 to the MODE parameter to set the auto-calibration routine.
3. Populate the input parameters required by the auto-calibration engine:
  - a. LRA\_ERM — selection depends on desired actuator.
  - b. FB\_BRAKE\_FACTOR[2:0] — A value of 3 is valid for most actuators.
  - c. LOOP\_GAIN[1:0] — A value of 2 is valid for most actuators.
  - d. RATED\_VOLTAGE[7:0] — See the [Section 7.6.2.1](#) section for calculating the correct register value.
  - e. OD\_CLAMP[7:0] — See the [Section 7.6.2.2](#) section for calculating the correct register value.
  - f. AUTO\_CAL\_TIME[1:0] — A value of 3 is valid for most actuators.
  - g. DRIVE\_TIME[3:0] — See the [Section 7.6.1.1](#) for calculating the correct register value.
  - h. SAMPLE\_TIME[1:0] — A value of 3 is valid for most actuators.
  - i. BLANKING\_TIME[3:0] — A value of 1 is valid for most actuators.
  - j. IDISS\_TIME[3:0] — A value of 1 is valid for most actuators.
  - k. ZC\_DET\_TIME[1:0] — A value of 0 is valid for most actuators.
4. Write a 1 to the GO bit to start the auto-calibration process. When auto calibration is complete, the GO bit automatically clears. The auto-calibration results are written in the respective registers as shown in [Figure 7-13](#).
5. Check the status of the DIAG\_RESULT bit to maintain that the auto-calibration routine is complete without faults.
6. Evaluate system performance with the auto-calibrated settings. Note that the evaluation occurs during the final assembly of the device because the auto-calibration process can affect actuator performance and behavior. If any adjustment is required, the inputs can be modified and this sequence can be repeated. If the performance is satisfactory, the user can do any of the following:
  - a. Repeat the calibration process upon subsequent power ups.
  - b. Store the auto-calibration results in host processor memory and rewrite them to the DRV2625 device upon subsequent power ups. The device retains these settings when in STANDBY mode or when the EN pin is low.

## **7.6.8 Waveform Playback Programming**

### **7.6.8.1 Data Formats for Waveform Playback**

The DRV2625 uses a signed data format (2's complement) to specify the magnitude and direction of the drive. The actuator can be driven in either closed-loop or open-loop. In closed-loop, positive numbers indicate the magnitude of the drive desired. Negative numbers are interpreted as a brake signal, which is automatic in closed-loop. In open-loop, positive and negative numbers are required to specify amplitude magnitude for both driving and braking. In the case that automatic braking is selected for open loop, then any negative number is interpreted as a brake signal.

### **7.6.8.2 Open-Loop Mode**

In open-loop mode, the reference level for full-scale drive is set by the OD\_CLAMP[7:0] parameter. A mid-scale input value gives no drive signal, and a less-than mid-scale gives a negative drive value. For an ERM, a negative drive value results in counter-rotation, or braking. For an LRA, a negative drive value results in a 180-degree phase shift in commutation.

### **7.6.8.3 Closed-Loop Mode**

In closed-loop mode, the DRV2625 device provides automatic overdrive and braking for both ERM and LRA devices. Positive values indicate that acceleration is desired. Negative values and 0 indicate that braking is desired.

The reference level for steady-state full-scale drive is set by the RATED\_VOLTAGE[7:0] bit (when auto-calibration is performed). The output voltage can momentarily exceed the rated voltage for automatic overdrive and braking, but does not exceed the OD\_CLAMP[7:0] voltage. Braking occurs automatically based on the input signal when the back-EMF feedback determines that braking is necessary.

In the event that the user is concerned that the overdrive time can be too high for a particular actuator, the OD\_CLAMP\_TIME[1:0] can be used to limit the amount of time spent in over-drive mode (a voltage above the rated voltage). If the overdrive time is exceeded and the DRV2625 device is still attempting to overdrive the actuator, a new clamp is enforced, which is specified in the RATED\_VOLTAGE\_CLAMP[7:0] parameter, which is enforced until a brake signal is received. During braking, the device is allowed to overdrive for the time specified in the OD\_CLAMP\_TIME[1:0], and, if exceeded, the RATED\_VOLTAGE\_CLAMP[7:0] is enforced. This feature maintains that the actuator is not overdriven continuously for longer than desired.

### 7.6.9 Waveform Setup and Playback

Playback of a haptic effect can occur in RTP mode or by using the waveform sequencer. And the process (either RTP or waveform sequencer) can be triggered by writing a 1 to the GO bit, or by using the external trigger in either trigger-pulse or trigger-level configuration. A waveform can be terminated prematurely by writing a 0 to the GO bit or by sending a stop trigger via the external TRIG/INTZ pin.

#### 7.6.9.1 Waveform Playback Using RTP Mode

The user can enter the RTP mode by writing to the MODE[1:0] parameter. In RTP mode, when the DRV2625 device received a trigger, the device drives the actuator continuously with the amplitude specified in the RTP\_INPUT[7:0] parameter. Because the amplitude tracks the value specified in the RTP\_INPUT[7:0] parameter, the I<sup>2</sup>C bus can stream waveforms. To stop driving the user can either change modes or send a stop trigger (either write 0 to the GO bit or using the external trigger).

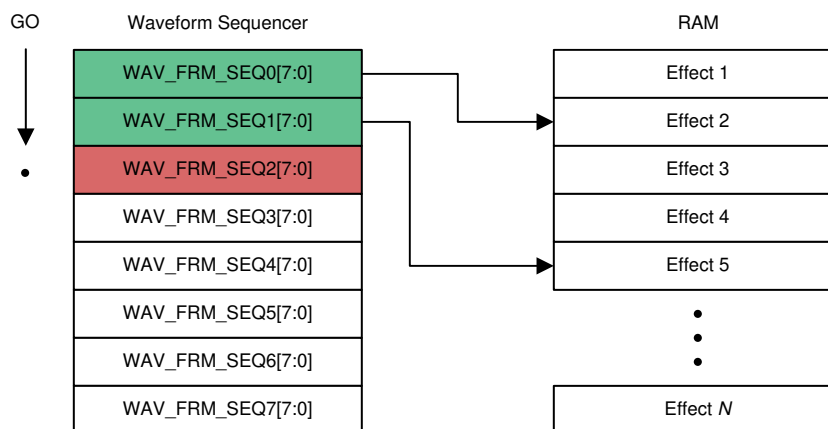

#### 7.6.9.2 Waveform Sequencer

To play haptic effects from the internal memory, the effects must first be loaded into the waveform sequencer, and then the effects can be launched by using any of the trigger options.

The waveform sequencer queues waveform-library identifiers for playback. Eight sequence registers queue up to eight library waveforms for sequential playback. A waveform identifier is an integer value referring to the index position of a waveform in the internal memory. Playback begins at WAV\_FRM\_SEQ1 when the user triggers the waveform sequencer. When playback of that waveform ends, the waveform sequencer plays the next waveform identifier held in WAV\_FRM\_SEQ2 (if non-zero). The waveform sequencer continues in this way until the sequencer reaches an identifier value of zero or until all eight identifiers are played whichever comes first.

The waveform identifier is a 7-bit number. The MSB of each sequence register can be used to implement a delay between sequence waveforms. When the MSB is high, bits 6:0 indicate the length of the wait time. The wait time for that step then becomes WAV\_FRM\_SEQ[6:0] × 10ms.

The DRV2625 device allows for looping of individual waveforms by using the WAVn\_SEQ\_LOOP parameters. When used, the state machine loops the particular waveform the number of times specified in the associated WAVn\_SEQ\_LOOP parameter before moving to the next waveform. Additionally, the entire sequencer of waveforms can be looped a number of times specified by the WAV\_SEQ\_MAIN\_LOOP parameter. The waveform-looping feature is useful for long, custom haptic playbacks, such as a haptic ringtone.

**Figure 7-14. Waveform Sequencer Programming**

#### 7.6.9.3 Waveform Playback Triggers

The DRV2625 device has 2 modes of waveform playback: Waveform Sequencer and RTP. Both modes can be triggered externally by using the TRIG/INTZ pin or internally by using the GO bit. If using external trigger, the TRIG\_PIN\_FUNC must be selected appropriately.

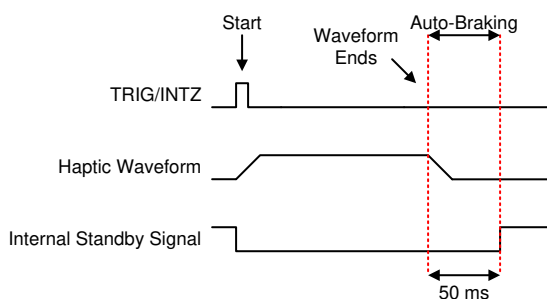

### 7.6.9.3.1 Playback Trigger Without Automatic Brake into Standby

When automatic braking into standby is disabled (AUTO\_BRK\_INTX\_STBY bit set to 0), playback can be triggered in both RTP and waveform sequencer modes with internal trigger by writing a 1 to the GO bit, and stopped by writing a 0 to the GO bit. Playback can also be triggered by the external trigger by following the trigger-pulse or trigger-level specifications (see Figure 7-4 and Figure 7-5 for details). Note that internal trigger is not available if the external trigger pin is set to trigger-level (TRIG\_PIN\_FUNC = 1)

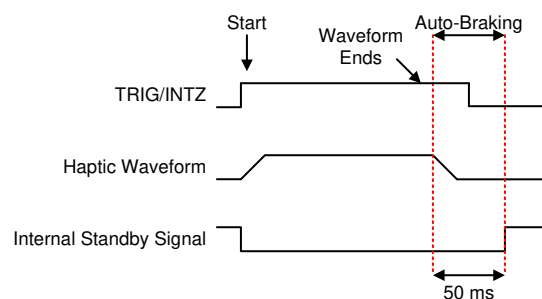

RTP playback (MODE[1:0] = 0), once triggered, runs indefinitely until the waveform is stopped. The waveform sequencer (MODE[1:0] = 1) runs until the sequencer reaches the end point and automatically goes into standby without a cancel trigger being received, unless an infinite loop is requested.

#### 7.6.9.3.1.1 Playback Trigger With Automatic Brake into Standby (SimpleDrive)

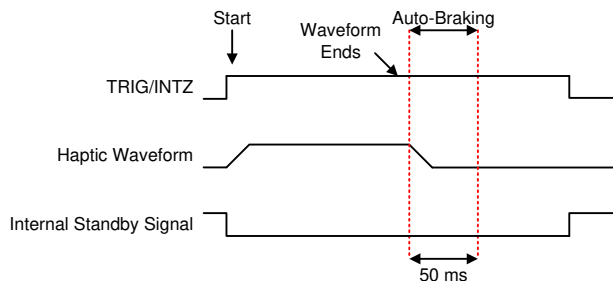

If automatic braking into standby is enabled (AUTO\_BRK\_INTX\_STBY bit is set to 1), then the device part goes into brake mode before going into standby. This feature introduces new timing requirements that are described in below diagrams.

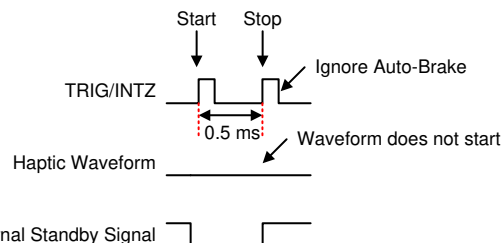

**Figure 7-15. Waveform Sequencer with Trigger-Pulse**

## 8.2 Address: 0x01

**Figure 8-2. 0x01**

7	6	5	4	3	2	1	0
DIAG_RESULT[0]	Reserved			PROCESS_DON E[0]	UVLO[0]	OVER_TEMP[0]	OC_DETECT[0]
R-0	R/W-0			R-0	R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-3. Address: 0x01**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7	DIAG_RESULT	R	0	The meaning of this bit changes depending on the mode of operation. In diagnostics mode, this bit asserts if the actuator is either open or short to ground, to VDD, or there is no valid BEMF signal. For the impedance measurement mode, refer to DIAG_Z_RESULT[7:0]. For the calibration mode, this bit asserts if the calibration fails. This bit is sticky and clears on read.
				0 No issue found.
				1 Either diagnostics, or calibration failed.
6-4	Reserved	R/W	0	Reserved
3	PROCESS_DONE	R	0	Shows if the process executed is done. This bit is sticky and clears on read.
				0 Process is not done.
				1 Process is done (either waveform sequencer, diagnostics or auto-calibration). This bit is cleared when read.
2	UVLO	R	0	If VDD drops below the UVLO_THRES[2:0], this bit asserts. This bit is sticky and clear on read.
				0 No VDD droop has been observed.
				1 A VDD droop is observed. Clears on read.
1	OVER_TEMP	R	0	Shows current status of the thermal protection. This bit is sticky and clears on read.
				0 Temperature is below over-temperature threshold
				1 Temperature is above over-temperature threshold. Clears on read.
0	OC_DETECT	R	0	Shows current status of the output overcurrent protection. This bit is sticky and clears on read.
				0 No over-current detected in OUT+ or OUT-
				1 Over-current detected in OUT+ or OUT-. Clears on read.

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7-0	VBAT[7:0]	R	0	This parameter provides a real-time reading of the supply voltage at the VDD pin. The device must be actively playing a waveform to take a reading.

## 8.6 Address: 0x05

R/W-0						RO-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-7. Address: 0x05**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7-2	Reserved	R/W	0	Reserved
1-0	LRA_PERIOD[9:0]	RO	0	This parameter reports the resonance frequency of the LRA in real time. Because this register is continuously being updated, the MSB section must be read first, the LSB (and the MSB) register is retained until the LSB is read to preserve consistency. If the waveform finishes and the LSB has not been read, the device automatically unlocks both registers (MSB and LSB) and the registers start to update again upon the next playback. For this reason, TI recommends reading both registers during the same playback to get accurate readings. LRA period = LRA_PERIOD[9:0] × 24.39μs. The accuracy of the reported frequency is not verified during braking.

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-9. Address: 0x07**

BITS	FIELD	TYPE	DEFAULT	DESCRIPTION
7	I2C_BCAST_EN	R/W	0	When enabled, the device responds to peripheral address 0x58 (or 1011000). This is useful for triggering multiple drivers at the same time. 0 Haptic Broadcast disable. 1 Haptic Broadcast enabled.
6	LRA_PERIOD_AVG_DIS	R/W	1	Enables/disables averaging for the resonance reporting located in LRA_PERIOD[9:0] parameter. 0 LRA_PERIOD[9:0] reports the average period of the last 4 periods. Uses a shift register preloaded with 0. 1 LRA_PERIOD[9:0] reports the last period.
5-4	LINEREG_COMP_SEL[1:0]	R/W	0	Applies a compensation factor to compensate for variations of LDO shifting. 0 0% 1 2% 2 4% 3 5%
3-2	TRIG_PIN_FUNC[1:0]	R/W	1	This parameter selects the function of the TRIG/INTZ pin. If this parameter is changed during process execution, the device goes into standby. 0 Pin functions as external pulse trigger (input). In this mode, the GO bit can also be used to trigger or cancel processes. 1 Pin functions as external level trigger - enable (input). In this mode the GO bit cannot be used. 2 Pin functions as an interrupt (open drain output). In this mode, the GO bit is the only mechanism to trigger and cancel processes. 3 Reserved
1-0	MODE[1:0]	R/W	0	This parameter is used to select the mode of operation. If the mode is changed during process execution, the device immediately goes into standby. 0 RTP Mode 1 Waveform Sequencer Mode 2 Diagnostics Routine 3 Automatic Level Calibration Routine

## 8.9 Address: 0x08

**Figure 8-9. 0x08**

7	6	5	4	3	2	1	0
LRA_ERM[0]	CONTROL_LOOP[0]	HYBRID_LOOP[0]	AUTO_BRK_OL[0]	AUTO_BRK_INT_O_STBY[0]	INPUT_SLOPE_CHECK[0]	Reserved	
R/W-1	R/W-0	R/W-0	R/W-0	R/W-1	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-10. Address: 0x08**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7	LRA_ERM	R/W	1	Selects the actuator type. This bit is set prior to running the calibration routine.
				0 ERM.
				1 LRA.
6	CONTROL_LOOP	R/W	0	Selects either closed loop or open loop mode. This applies to both ERM and LRA actuators.
				0 Closed Loop.
				1 Open Loop.
5	HYBRID_LOOP	R/W	0	Selects between full closed loop mode and hybrid closed-loop mode.
				0 Full closed loop mode.
				1 Hybrid loop mode.
4	AUTO_BRK_OL	R/W	0	Provides automatic braking for ERM and LRA when in open loop. To achieve this, when the data to be played is 0 or less, the DRV2625 device automatically goes into closed loop mode and then brakes the actuator. Note that when the data to be played is positive the device plays in open loop mode. This feature assumes that the actuator has been calibrated and that the actuator functions correctly under closed-loop conditions. This feature is disabled by default.
				0 No automatic braking while in open loop mode.
				1 Automatic braking for open loop mode is enabled. Goes to closed-loop mode to break when data is 0 or less.
3	AUTO_BRK_INT_O_STBY	R/W	1	This bit is used to enable automatic braking when the device goes into standby. If this bit is set and a waveform is playing, when a go-to-standby signal is received (either from the timer, or the EN functionality of the TRIG/INTZ pin), the device first brakes the actuator and then transitions to the standby mode.
				0 Go immediately to standby mode (without automatic braking).
				1 Before going to standby mode, check if the actuator is moving. If the actuator is moving brake the actuator and then go to standby mode. If the actuator is not moving then go into standby mode.
2	INPUT_SLOPE_CHECK	R/W	0	If bit is set, driver operates in open loop and only changes to close loop if the transition requested is big enough. This bit is ignored if hybrid loop is disabled.
				0 No input slope check.
				1 Input slope check enabled
1-0	Reserved	R/W	0	Reserved

R/W-0							R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-14. Address: 0x0C**

BITS	FIELD	TYPE	DEFAULT	DESCRIPTION
7-1	Reserved	R/W	0	Reserved
0	GO	R/W	0	This bit is used to fire processes. The process fired by the GO bit is selected by the MODE parameter. The primary function of this bit is to fire playback of the waveform identifiers in the waveform sequencer (registers 0x0F to 0x16), in which case, this bit can be thought of a software trigger for haptic waveforms. The GO bit remains high until the process has completed. Clearing the GO bit during waveform playback cancels the process immediately. Using the external trigger also asserts the GO bit in a similar way as if the assertion is written. The GO bit can be used to play effects using the waveform sequencer, run auto-calibration, and run diagnostics.

### 8.14 Address: 0x0D

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-16. Address: 0x0E**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7-0	RTP_INPUT[7:0]	R/W	127	This parameter is the entry point for real-time playback (RTP) data. The digital playback engine drives the RTP_INPUT[7:0] value to the load when MODE[1:0] parameter is set to RTP mode, and the RTP process is triggered. The RTP_INPUT[7:0] value can be updated in real-time by the host controller to create haptic waveforms. The TP_INPUT[7:0] value is interpreted as an 8-bit signed number.

## 8.16 Address: 0x0F

**Figure 8-16. 0x0F**

7	6	5	4	3	2	1	0
WAIT1[0]	WAV_FRM_SEQ1[6:0]						
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-17. Address: 0x0F**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7	WAIT1	R/W	0	When this bit is set, the WAV_FRM_SEQ1[6:0] is interpreted as a wait time in which the playback engine idles. This bit is used to insert timed delays between sequentially played waveforms. Delay time = 10ms × WAV_FRM_SEQ1[6:0]. If this bit is 0, then WAV_FRM_SEQ1[6:0] is interpreted as a waveform identifier for sequence playback.
				0 WAV_FRM_SEQ1[6:0] is interpreted as a waveform identifier for sequence playback.
				1 WAV_FRM_SEQ1[6:0] is interpreted as a delay.
6-0	WAV_FRM_SEQ1[6:0]	R/W	1	This parameter holds the waveform identifier of the waveform to be played. A waveform identifier is an integer value referring to the index position of a waveform in the library. Playback begins at register address 0x0F when the user asserts the GO bit (register 0x0C). When playback of that waveform ends, the waveform sequencer plays the ext waveform identifier held in register 0x10, if the next waveform identifier is non-zero. The waveform sequencer continues in this way until he sequencer reaches an identifier value of zero, or all eight identifiers are played (register addresses 0x0F through 0x16), whichever comes first. If WAIT1 is set to 1, then this parameter is used to insert a delay given by: Delay time = 10ms × WAV_FRM_SEQ1[6:0].
				0 Signals the waveform sequencer to stop when the waveform sequencer attempts to play this identifier.

## 8.17 Address: 0x10

			1	WAV_FRM_SEQ8[6:0] is interpreted as a delay.
6-0	WAV_FRM_SEQ8[6:0]	R/W	0	This parameter holds the waveform identifier of the waveform to be played. A waveform identifier is an integer value referring to the index position of a waveform in the library. Playback begins at register address 0x0F when the user asserts the GO bit (register 0x0C). When playback of that waveform ends, the waveform sequencer plays the next waveform identifier held in register 0x10, if the next waveform identifier is non-zero. The waveform sequencer continues in this way until the sequencer reaches an identifier value of zero, or all eight identifiers are played (register addresses 0x0F through 0x16), whichever comes first. If WAIT8 is set to 1, then this parameter is used to insert a delay given by: Delay time = 10ms × WAV_FRM_SEQ8[6:0].
			0	Signals the waveform sequencer to stop when the waveform sequencer attempts to play this identifier.

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-35. Address: 0x22**

BITS	FIELD	TYPE	DEFAULT	DESCRIPTION
7-0	A_CAL_BEMF[7:0]	R/W	109	The digital playback engine uses this value to automatically determine the appropriate feedback gain for closed-loop operation.

## 8.35 Address: 0x23

**Figure 8-35. 0x23**

7	6	5	4	3	2	1	0
NG_THRESH[0]	FB_BRAKE_FACTOR[2:0]			LOOP_GAIN[1:0]		BEMF_GAIN[1:0]	
R/W-0	R/W-0	R/W-1	R/W-1	R/W-0	R/W-1	R/W-1	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

**Table 8-36. Address: 0x23**

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7	NG_THRESH	R/W	0	Output noise gate control. If the driver intends to drive a magnitude below the threshold selected in this bit, the output driver sends 0 (no output). 0 4% of VDD. 1 8% of VDD.
6-4	FB_BRAKE_FACTOR[2:0]	R/W	3	Selects the feedback gain ratio between braking gain and driving gain. In general, adding additional feedback gain while braking so that the actuator brakes as quickly as possible is desirable. Large ratios give less stable operation than lower ones. The advanced user can choose to optimize this register. Otherwise, the default value gives good performance for most actuators. This value is set prior to running auto calibration. 0 1. 1 2. 2 3. 3 4. 4 6. 5 8. 6 16. 7 Removes feedback during braking (braking disabled).
3-2	LOOP_GAIN[1:0]	R/W	1	Selects a loop gain for the feedback control. This sets how fast the loop tries to make the back-EMF (and thus motor velocity) match the input signal level. Higher loop gain (faster settling) options gives less stable operation than lower loop gain (slower settling). The advanced user can choose to optimize this register. Otherwise, the default value gives good performance for most actuators. This value is set prior to running auto calibration. 0 Very Slow. 1 Slow. 2 Fast. 3 Very Fast.
1-0	BEMF_GAIN[1:0]	R/W	2	Sets the analog gain of the back-EMF amplifier. This value is interpreted differently between ERM mode and LRA mode. Auto calibration automatically populates BEMF_GAIN with the most appropriate value for the actuator. Note that a user can overwrite this value. 0 5x for LRA Mode, 0.34x for ERM Mode. 1 10x for LRA Mode, 1.05x for ERM Mode. 2 20x for LRA Mode, 1.82x for ERM Mode. 3 30x for LRA Mode, 4x for ERM Mode.

BIT	FIELD	TYPE	DEFAULT	DESCRIPTION
7-2	Reserved	R/W	0	Reserved
1-0	AUTO_CAL_TIME[1:0]	R/W	2	Duration of autocal routine. Sets the length of the auto calibration time. This is enough time for the motor acceleration to settle when driven at the RATED_VOLTAGE value.
				0 250ms.
				1 500ms.
				2 1000ms.
				3 Duration is trigger controlled (either external trigger, enable, or internal trigger). Minimum duration is 1s, otherwise the result of the calibration can be corrupted. Once the cancellation trigger is received, the calibration measurements is taken, which can take several milliseconds to complete.

## Application and Implementation

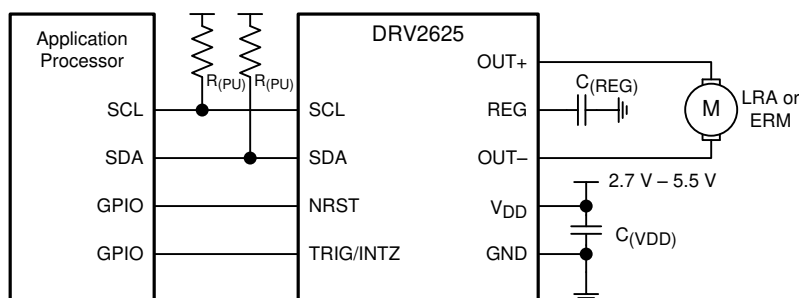

### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

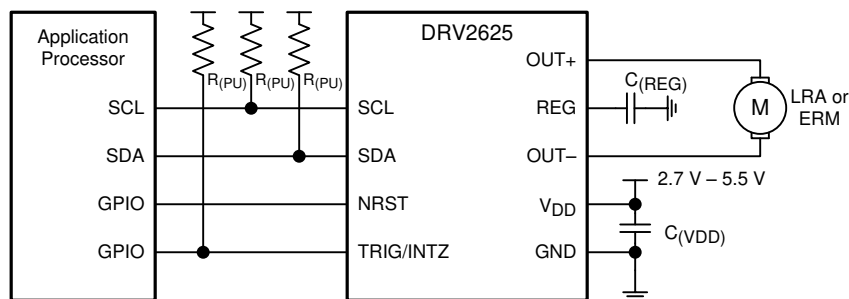

## 1 Application Information

The typical application for a haptic driver is in a touch-enabled system that already has an application processor which makes the decision on when to execute haptic effects.

The DRV2625 device can be used fully with I<sup>2</sup>C communications (either using RTP or the memory interface). A system designer can choose to use external triggers to play low-latency effects (such as from a physical button). [Figure 9-1](#) and [Figure 9-2](#) show typical haptic system implementations. The system designer should not use the internal regulator (REG) to power any external load.

**Figure 9-1. I<sup>2</sup>C Control with Optional External Trigger**

**Figure 9-2. I<sup>2</sup>C Control with Optional Interrupt Pin**

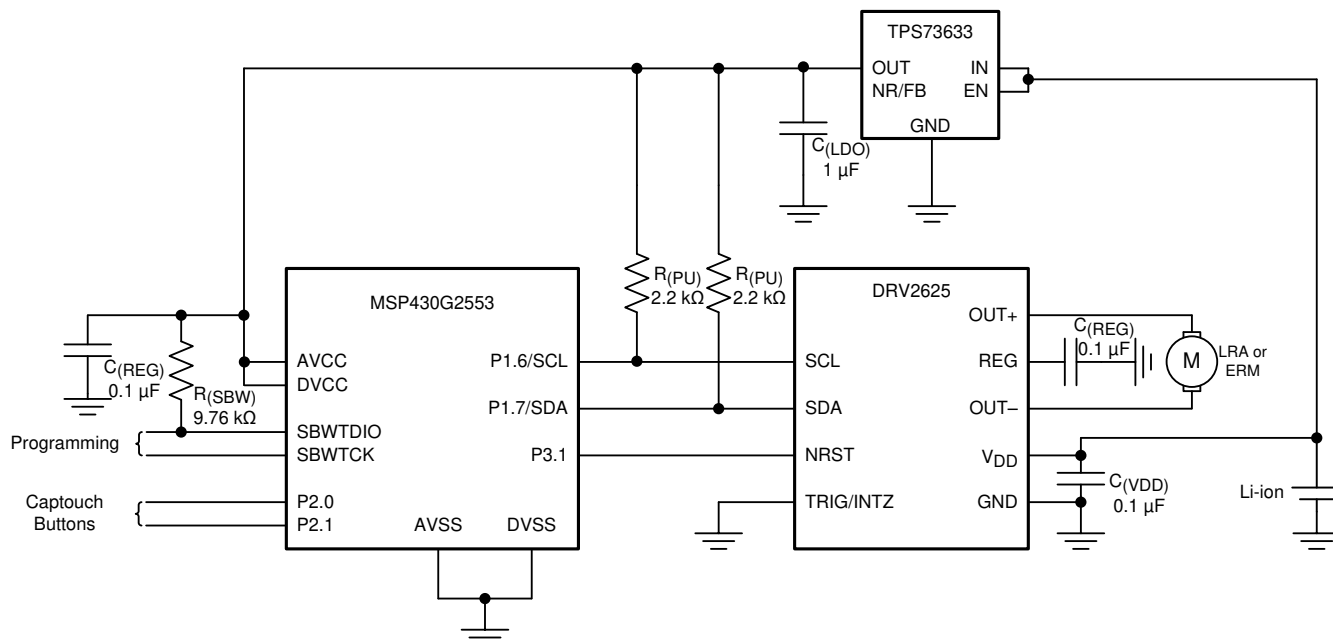

**Table 9-1. Recommended External Components**

COMPONENT	DESCRIPTION	SPECIFICATION	TYPICAL VALUE
C <sub>(VDD)</sub>	Input capacitor	Capacitance	0.1 $\mu$ F
C <sub>(REG)</sub>	Regulator capacitor	Capacitance	0.1 $\mu$ F
R <sub>(PU)</sub>	Pull-up resistor	Resistance	2.2 k $\Omega$

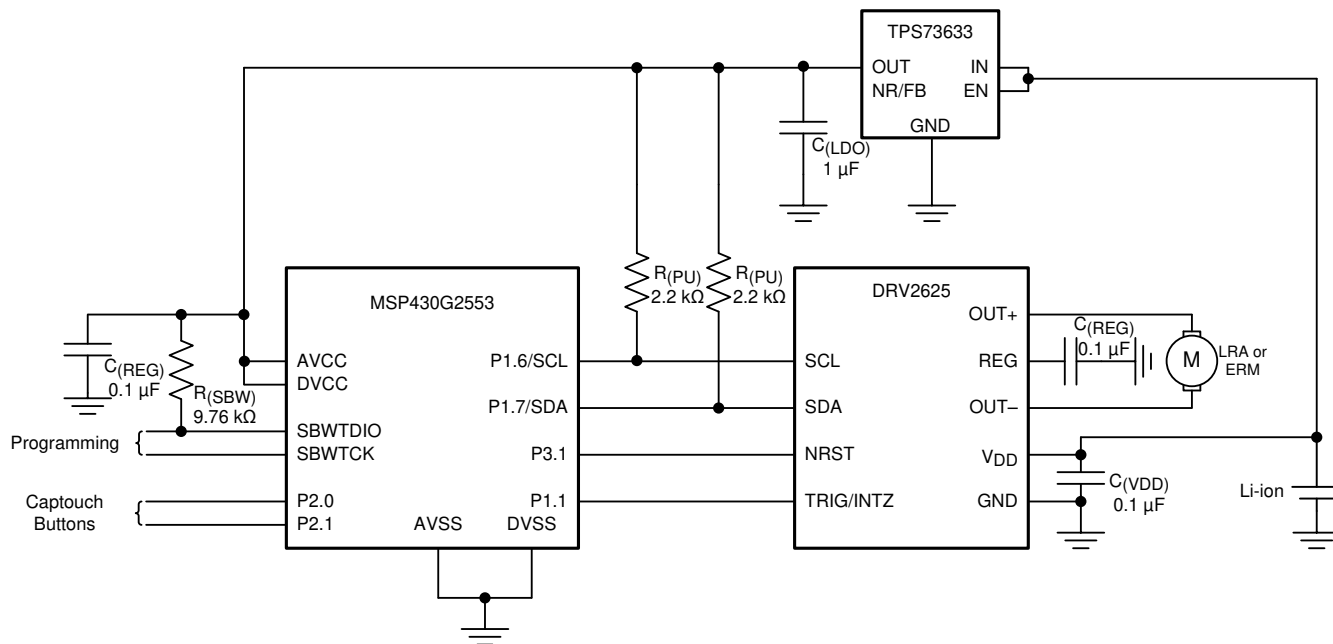

## 2 Typical Application

A typical application of the DRV2625 device is in a system that has external buttons which fire different haptic effects when pressed. [Figure 9-3](#), [Figure 9-4](#) and [Figure 9-5](#) show typical schematics of such a system. The buttons can be physical buttons, capacitive-touch buttons, or GPIO signals coming from the touch-screen system.

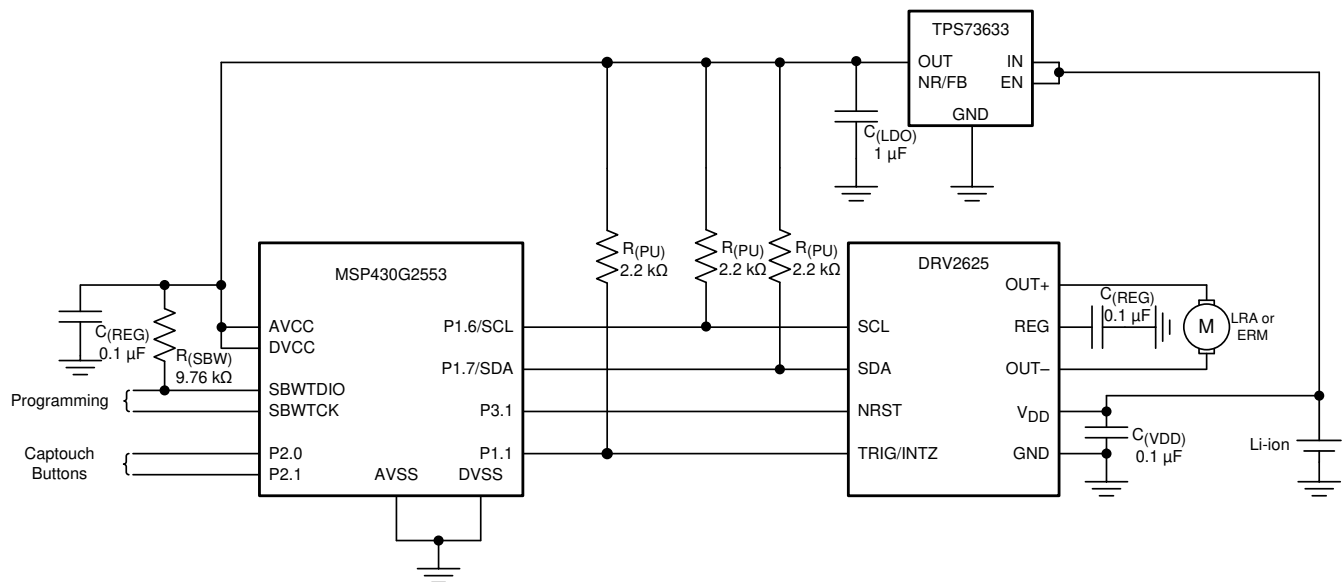

Effects in this type of system are programmable.

**Figure 9-3. Typical Application Schematic Without External Trigger or Interrupt Pin**

**Figure 9-4. Typical Application Schematic With External Trigger**

**Figure 9-5. Typical Application Schematic With Interrupt Pin**

## 2.1 Design Requirements

For this design example, use the values listed in [Table 9-2](#) as the input parameters.

**Table 9-2. Design Parameters**

DESIGN PARAMETER	EXAMPLE VALUE
Interface	I <sup>2</sup> C, external trigger
Actuator type	LRA, ERM
Input power source	Li-ion/Li-polymer, 5-V boost

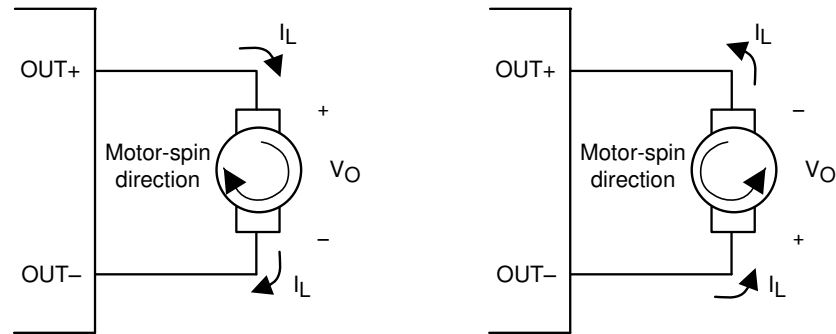

## 2.2 Detailed Design Procedure

### 2.2.1 Actuator Selection

The actuator decision is based on many factors including cost, form factor, vibration strength, power-consumption requirements, haptic sharpness requirements, reliability, and audible noise performance. The actuator selection is one of the most important design considerations of a haptic system and therefore the actuator is the first component to consider when designing the system. The following sections list the basics of ERM and LRA actuators.

#### 2.2.1.1 Eccentric Rotating-Mass Motors (ERM)

Eccentric rotating-mass motors (ERMs) are typically DC-controlled motors of the bar or coin type. ERMs can be driven in the clockwise direction or counter-clockwise direction depending on the polarity of voltage across the two pins. Bidirectional drive is made possible in a single-supply system by differential outputs that are capable of sourcing and sinking current. This feature helps eliminate long vibration tails which are undesirable in haptic feedback systems.

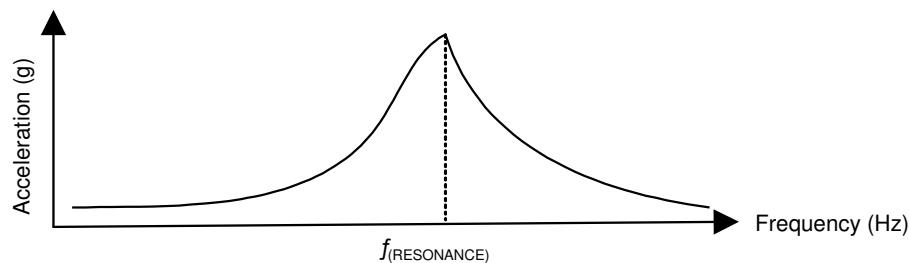

**Figure 9-6. Motor Spin Direction in ERM Motors**

Another common approach to driving DC motors is the concept of overdrive voltage. To overcome the inertia of the mass of the motor, these motors are often *overdriven* for a short amount of time before returning to the rated voltage of the motor to sustain the rotation of the motor. Overdrive is also used to stop (or brake) a motor quickly. Refer the data sheet of the motor for safe and reliable overdrive voltage and duration.

#### 2.2.1.2 Linear Resonance Actuators (LRA)

Linear resonant actuators (LRAs) vibrate at the resonant frequency. LRAs have a high-Q frequency response because of a rapid drop in vibration performance at the offsets of 3 to 5Hz from the resonant frequency. Many factors also cause a shift or drift in the resonant frequency of the actuator such as temperature, aging, the mass of the product to which the LRA is mounted, and in the case of a portable product, the manner in which the product is held. Furthermore, as the actuator is driven to the maximum allowed voltage, many LRAs shifts several hertz in frequency because of mechanical compression. All of these factors make a real-time tracking auto-resonant algorithm critical when driving LRA to achieve consistent, peak performance.

**Figure 9-7. Typical LRA Response**

##### 2.2.1.2.1 Auto-Resonance Engine for LRA

The DRV2625 auto-resonance engine tracks the resonant frequency of an LRA in real time effectively locking into the resonance frequency after half a cycle. If the resonant frequency shifts in the middle of a waveform for any reason, the engine tracks the frequency from cycle to cycle. The auto resonance engine accomplishes the tracking by constantly monitoring the back-EMF of the actuator. Note that the auto resonance engine is not affected by the auto-calibration process which is only used for level calibration. No calibration is required for the auto resonance engine.

#### 2.2.2 Capacitor Selection

The DRV2625 device has a switching output stage which pulls transient currents through the  $V_{DD}$  pin. Placing a 0.1- $\mu$ F low equivalent-series-resistance (ESR) supply-bypass capacitor of the X5R or X7R type near the  $V_{DD}$  supply pin is recommended for proper operation of the output driver and the digital portion of the device. Place a 0.1- $\mu$ F X5R or X7R-type capacitor from the REG pin to ground.

#### 2.2.3 Interface Selection

The DRV2625 device is designed with a default configuration that supports a wide variety of LRA actuators. If an actuator compatible with the default of the device is selected, then the SimpleDrive can be used without

the use of I<sup>2</sup>C interface. For this case, the user has 3 options available: controlling the NRST and TRIG/INTZ pin independently (4 pin interface: VDD, GND, NRST, TRIG/INTZ), shorting NRST with TRIG/INTZ pin and controlling them with a single GPIO (3 pin interface: VDD, GND, TRIG), or shorting NRST, TRIG/INTZ and VDD together (2 pin interface: VDD, GND). Note that for the 2-pin interface, the VDD signal must ramp faster than the startup time (about 500µs) otherwise a UVLO condition is detected which prevents the device from playing the desired waveform

The I<sup>2</sup>C interface is required to configure the device. The device can be used fully with this interface with either RTP or internal memory. The advantage of using this interface is that no additional GPIO (for the TRIG/INTZ pin) is required for firing effects. Therefore the TRIG/INTZ pin can be connected to GND. Using the external trigger pin has the advantage that no I<sup>2</sup>C transaction is required to fire the pre-loaded effect, which is a good choice for interfacing with a button.

#### 2.2.4 Power Supply Selection

The DRV2625 device supports a wide range of voltages in the input. Maintaining that the battery voltage is high enough to support the desired vibration strength with the selected actuator is an important design consideration. The typical application uses Li-ion or Li-polymer batteries which provide enough voltage headroom to drive most common actuators.

If very strong vibrations are desired, a boost converter can be placed between the power supply and the V<sub>DD</sub> pin to provide a constant voltage with a healthy headroom (5V rails are common in some systems) which is particularly true if 2 AA batteries in series are being used to power the system.

### 2.3 Application Curves

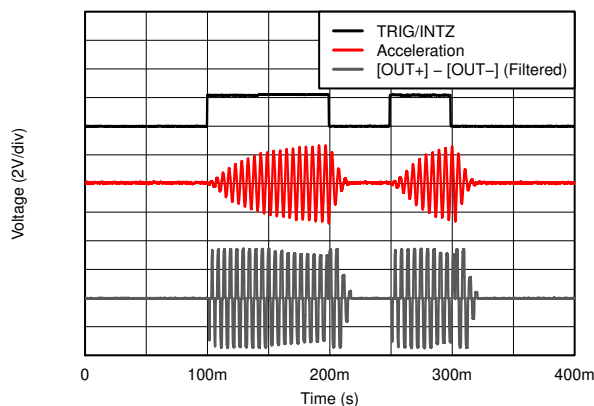

Figure 9-8. LRA SimpleDrive

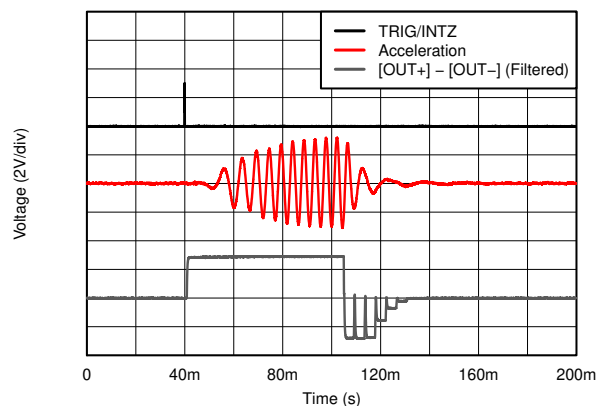

Figure 9-9. ERM Open-Loop Drive with Automatic Brake

## 3 Initialization Set Up

### 3.1 Initialization Procedure

1. After power-up, wait at least 1 ms before the DRV2625 device accepts I<sup>2</sup>C commands.
2. Assert the NRST pin (logic high). The NRST pin can be asserted any time during or after the wait period.
3. Write the MODE parameter (address 0x01) to value 0x00 to remove the device from standby mode.
4. Run auto-calibration to configure the DRV2625 device for the desired actuator. Alternatively, rewrite the results from a previous calibration.
5. If using the embedded ROM library, write the library selection bit (LIB\_SEL) to select a library.

### Note

The DRV2625 device defaults to closed-loop mode with external trigger option selected in the level (enable) configuration and in RTP mode. To use other modes and features, refer to the register map.

## 3.2 Typical Usage Examples

### 3.2.1 Play a Waveform or Waveform Sequence from the ROM Waveform Memory

1. Initialize the device as listed in the [Section 9.3.1](#) section.
2. Select the desired TRIG/INTZ pin function by changing the TRIG\_PIN\_FUNC parameter.
3. Identify the waveform index to be played and populate the waveform sequencer.
4. Trigger the waveform using the desired trigger method (GO bit, or external trigger). Note that if using the interrupt functionality, only the GO bit can be used to trigger the process.
5. Device automatically goes into standby upon completion of the playback

### 3.2.2 Play a Real-Time Playback (RTP) Waveform

1. Initialize the device as shown in the [Section 9.3.1](#) section.
2. Write the desired drive amplitude to the real-time playback input register RTP\_INPUT[7:0].
3. Trigger the waveform using the desired trigger method (GO bit, or external trigger). Note that if using the interrupt functionality, only the GO bit can be used to trigger the process.
4. Continue writing to the RTP\_INPUT[7:0] if/when desired to achieve the desired haptic effect.
5. Send a stop trigger using the desired trigger method (GO bit, or external trigger). Note that if using the interrupt functionality, only the GO bit can be used to trigger the process.
6. Device automatically goes into standby upon completion of the playback

## 4 Power Supply Recommendations

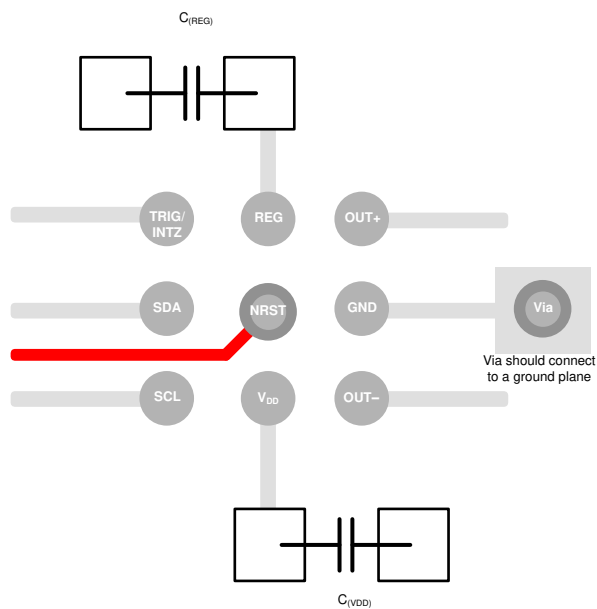

The DRV2625 device is designed to operate from an input-voltage supply range between 2.7V to 5.5V. The decoupling capacitor for the power supply is placed closed to the device pin.

## 5 Layout

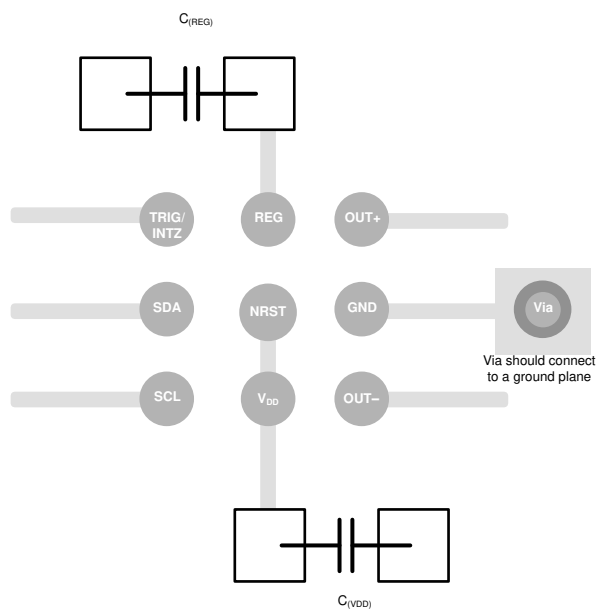

### 5.1 Layout Guidelines

The decoupling capacitor for the power supply ( $V_{DD}$ ) is placed close to the device pin. The filtering capacitor for the regulator (REG) is placed close to the device REG pin. When creating the pad size for the WCSP pins, TI recommends that the PCB layout use nonsolder mask-defined (NSMD) land. With this method, the solder mask opening is made larger than the desired land area and the opening size is defined by the copper pad width.

## 5.2 Layout Examples

**Figure 9-10. Typical Layout**

**Figure 9-11. Layout without NRST Functionality**

## 10 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

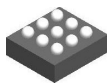

<b>Changes from Revision B (September 2016) to Revision C (June 2025)</b>	<b>Page</b>
• Added equation for calculating VBAT voltage.....	16
• Added note for corner case condition where the device can get stuck in a pseudo-standby state.....	16
• Added note for condition where the trigger may not enable the waveform to play.....	18
• Added note for condition where the trigger may not enable the waveform to play.....	18
• Added note for extra power consumption when INTZ is pulled high.....	19
• Added information about the pseudo-standby state.....	20
• For ERM mode, set the LRA_ERM bit to 0.....	28
• For LRA mode, set the LRA_ERM bit to 1.....	28

<b>Changes from Revision A (December 2015) to Revision B (September 2016)</b>	<b>Page</b>
• Updated REV[3:0] from 2 to 3 .....	37
• Changed Default of 0x00 Register .....	37
• Changed Default of 0x07 Register .....	40
• Changed Bits 7 and 6 of 0x0D Register .....	43
• Changed the calculation value for the open loop LRA drive of register 0x2E from 'OL_LRA_PERIOD[9:0] × 24.39µs' to 'OL_LRA_PERIOD[9:0] × 24.615µs'.....	60

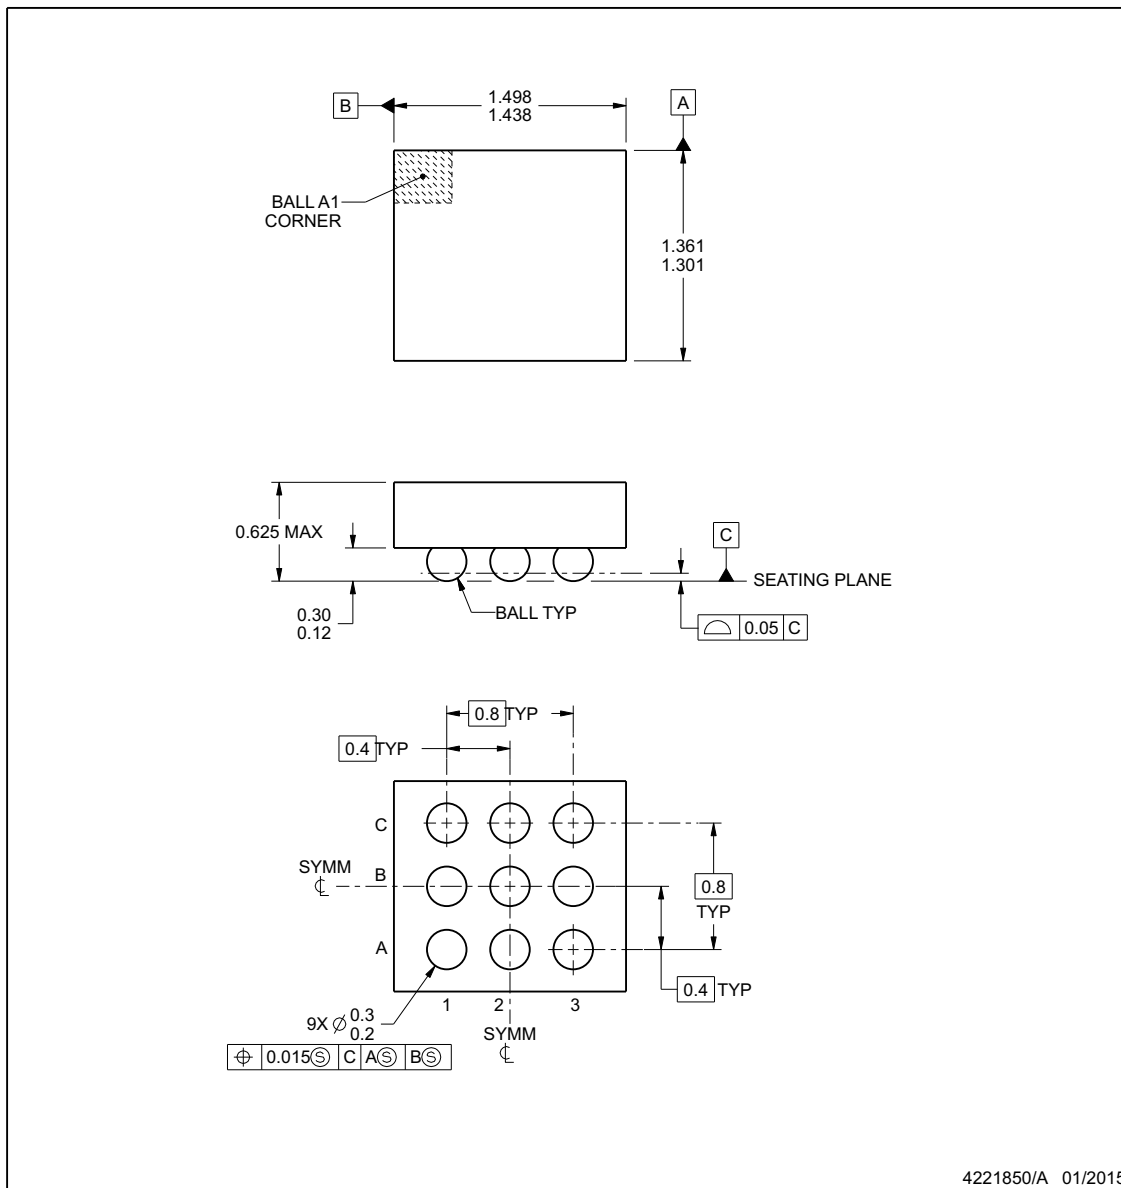

<b>Changes from Revision * (December 2015) to Revision A (December 2015)</b>	<b>Page</b>
• Changed data sheet from Product Preview to Production Data.....	1

## Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

DRV2625YFFT.A	Active	Production	DSBGA (YFF)   9	250   SMALL T&R	-	SNAGCU	Level-1-260C-UNLIM	-40 to 85	2625

<sup>(1)</sup> **Status:** For more details on status, see our [product life cycle](#).

<sup>(2)</sup> **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

<sup>(3)</sup> **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

<sup>(4)</sup> **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

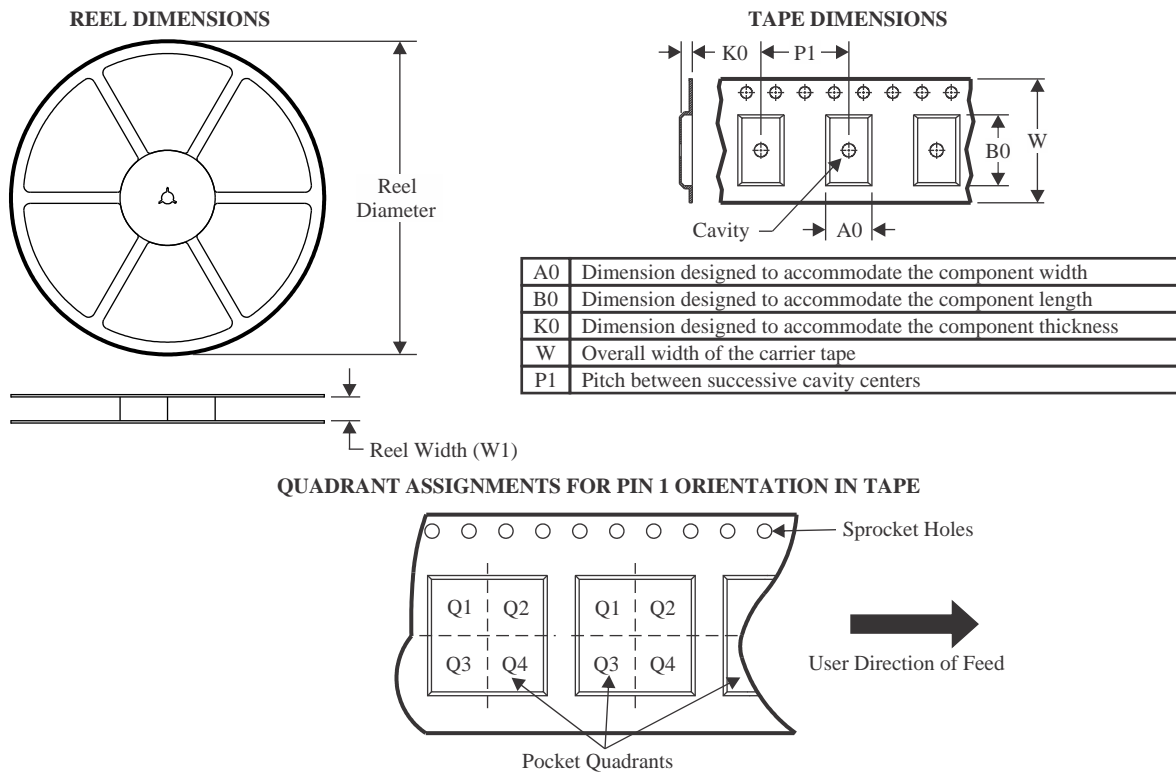

<sup>(6)</sup> **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#) or other applicable terms available either on [ti.com](https://www.ti.com) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
