ADVANCED VOLTAGE REGULATOR

- ENABLE AND SENSE INPUTS (EN, SI) PROTECTED AGAINST NEGATIVE TRANSIENTS DOWN TO -5V
- RESET THRESHOLD ADJUSTABLE FROM 3.8 TO 4.7V
- EXTREMELY LOW QUIESCENT CURRENT, 65µA (LESS THAN 90µA) IN STANDBY MODE
- OPERATING DC SUPPLY VOLTAGE RANGE 5V - 28V
- OPERATING TRANSIENT SUPPLY VOLTAGE UP TO 40V
- HIGH PRECISION STANDBY OUTPUT VOLTAGE $5V \pm 1\%$ WITH 100mA CURRENT CAPABILITY
- OUTPUT 2 VOLTAGE $5V \pm 2\%$ WITH 400mA CURRENT CAPABILITY (ADJ WIRED TO V_{OUT2})
- OUTPUT 2 VOLTAGE ADJUSTABLE BY EXTERNAL VOLTAGE DIVIDER
- OUTPUT 2 DISABLE FUNCTION FOR STANDBY MODE

DESCRIPTION

The L4938E/ED/EPD is a monolithic integrated dual voltage regulator with two very low dropout outputs and additional functions as power-on reset and input voltage sense. It is designed for supplying the microcomputer controlled systems especially in automotive applications.

Note :

- 4) The reset threshold can be programmed continuously from typ 3.8V to 4.7V by changing a value of an external resistor from pin PR to GN
- 5) This is a minimum reset time according to the hysteresis of the comparator. Delay time starts with V_{OUT1} exceeding V_{RT}
- 6) This is the nominal reset time depending on the discharging limit of C_T (saturation voltage) and the upper threshold of the timer comparator. Delay time starts with V_{OUT1} exceeding V_{RT}
- 7) The leakage of C_T must be less than 0.5mA (2V). If an external resistor between C_T and V_{OUT1} is applied, the leakage current may be increased. The external resistor should have more than 30K Ω .
for stability: $C_S \geq 1\mu F$, $C_{O1} \geq 10\mu F$, $C_{O2} \geq 10\mu F$, $ESR \leq 5\Omega$ (designed target) For details see application note.
- 8) For transients exceeding 20V or -20V external protection is required at the Pins SI and EN as shown at Pin EN. The protection proposed will provide proper function for transients in the range of $\pm 200V$. If the zener diode is omitted the external resistor should be raised to 200K Ω to limit the current to 1mA. Without the zener diode, the function 20V or -20V can not be guaranteed.

Connecting a resistor divider R_{1E} , R_{2E} to the ADJ, OUT2 pin the output voltage 2 can be programmed to the value of

$$V_{OUT2} = V_{OUT1} \left(1 + \frac{R_{1E}(R_{2E} + R_{ADJ})}{R_{2E} \cdot R_{ADJ}} \right)$$

with $R_{ADJ} = 60K$ to $150K$ and $V_{OUT1} = 4.95$ to $5.05V$.

For an exact calculation the temperature coefficient (T_c -2000ppm) of the internal resistor (R_{ADJ}) must be taken into account. Pin ADJ in this mode should not have a capacitive burden because this would reduce the phase margin of the regulator loop.

Reset circuit

The reset circuit supervises the standby output voltage. The reset output (RES) is defined from $V_{OUT} \geq 1V$.

Even if V_S is lacking, the reset generator is supplied by the output voltage V_{OUT1} .

The reset threshold of $4.7V$ is defined with the internal reference voltage (note 9) and standby output divider, when pin PR is left open. The reset threshold voltage can be programmed in the range from $3.8V$ to $4.7V$ by connecting an external resistor from pin PR to GND.

The value of the programming resistor R_{PR} can be calculated with:

$$R_{PR} = \frac{22K}{\frac{4.7K}{V_{RT}} - 1} - 92.9K, 3.8V \leq V_{RT} \leq 4.7V$$

The reset pulse delay time t_{RD} , is defined with the charge time of an external capacitor C_T :

$$t_{RDmin} = \frac{C_T \cdot 0.6V}{1\mu A} \text{ (note 5)}$$

$$t_{RDnom} = \frac{C_T \cdot 1.4V}{1\mu A} \text{ (note 6)}$$

The reaction time of the reset circuit originates from the noise immunity. Standby output voltage drops below the reset threshold only a bit longer than the reaction time results in a shorter reset delay time. The nominal reset delay time will be generated for standby output voltage drops longer

than approximately $50\mu s$.

The minimum reset time is generated if reset condition only occurs for a short time triggering a reset pulse but not completely discharging C_T . The reset can be related to output2 on request. If higher charge currents for the reset capacitor are required a resistors from Pin C_T to OUT1, may be used to increase the current. We recommended the use of $10K\Omega$ to $5V$ as an output pull up.

Sense Comparator

The sense comparator compares an input signal with an internal voltage reference of typical $1.23V$. The use of an external voltage divider makes this comparator very flexible in the application. It can be used to supervise the input voltage either before or after the protection diode and to give additional information to the microprocessor like low voltage warnings. We recommended the use of $10K\Omega$ to $5V$ as an output pull up.

Note 9:

The reference is alternatively supplied from V_S or V_{OUT1} . If one supply is present, the reference is operating.

Thermal Protection

Both outputs are provided with an overtemperature shut down regulation power dissipation down to uncritical values.

Output 2 will shut down approximately $10K$ before output 1.

Under normal conditions shut down of output 2 will allow the chip to cool down again. Thus output 1 will be unaffected.

The thermal shut down reduces the output voltages until power dissipation and the flow of thermal energy out of the chip balance.

Transient Sensitivity

In proper operation ($V_{OUT} > 4.5V$) the reference is supplied by V_{OUT1} thus reducing sensitivity to input transients.

Precise Data will be issued as soon as samples are available.
