Description

Electrical Characteristics

The electrical characteristics of an SMT50 device is similar to that of a self-gated Triac, but the SMT50 is a two terminal device with no gate. The gate function is achieved by an internal current controlled mechanism.

Like the T.V.S. diodes, the SMT50 has a standoff voltage (Vrm) which should be equal to or greater than the operating voltage of the system to be protected. At this voltage (Vrm) the current consumption of the SMT50 is negligible and will not affect the protected system.

When a transient occurs, the voltage across the SMT50 will increase until the breakdown voltage (Vbr) is reached. At this point the device will operate in a similar way to a T.V.S. device and is in an avalanche mode.

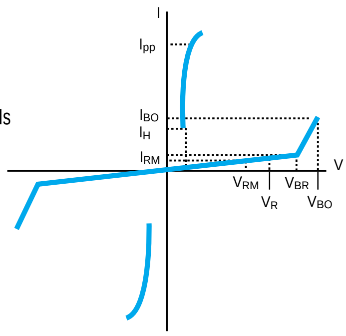
The voltage of the transient will now be limited and will only increase by a few volts as the device diverts more current. As this transient current rises, a level of current through the device is reached (Ibo) which causes the device to switch to a fully conductive state such that the voltage across the device is now only a few volts (Vt). The voltage at which the device switches from the avalanche mode to the fully conductive state (Vt) is known as the Breakover Voltage (Vbo). When the device is in the Vt state, high currents can be diverted without damage to the SMT50 due to the low voltage across the device, since the limiting factor in such devices is dissipated power (V x I).

Resetting of the device to the non conducting state is controlled by the current flowing through the device. When the current falls below a certain value, known as the Holding Current (I_H), the device resets automatically.

As with the avalanche T.V.S. device, if the SMT50 is subjected to a surge current which is beyond its maximum rating, then the device will fail in short circuit mode, ensuring that the equipment is ultimately protected.

Selecting A SMT50

1. When selecting an SMT50 device, it is important that the Vrm of the device is equal to or greater than the operating voltage of the system.
2. The minimum Holding Current (I_H) must be greater than the current the system is capable of delivering otherwise the device will remain conducting following a transient condition.



V-I Graph illustrating symbols and terms for the SMT50 surge protection device
