

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

General Description

The MAX9729 stereo DirectDrive™ headphone amplifier features bass boost, volume control, an input mux, and an I²C/SMBus™-compatible serial interface. This makes the MAX9729 ideal for portable audio applications where space is at a premium and performance is essential. The MAX9729 operates from a single 1.8V to 3.6V, and uses Maxim's patented† DirectDrive architecture, eliminating the need for large DC-blocking capacitors. The headphone amplifiers deliver 52mW into a 32Ω load, feature low 0.03% THD+N, and high 90dB PSRR. Maxim's industry-leading click-and-pop suppression circuitry reduces audible transients during power and shutdown cycles.

The BassMax feature boosts the bass response of the amplifier, improving audio reproduction for low-end headphones. The integrated volume control features 32 discrete volume levels along with a ramping function to ensure smooth transitions during shutdown cycles and input selection. The MAX9729's eight programmable maximum gain settings allow for a wide range of input signal levels. A 3:1 multiplexer/mixer allows the selection and summation of multiple stereo input signal sources. The MAX9729 also includes a dedicated BEEP input with independent attenuation control. BassMax, volume control, gain settings, and input selection are controlled using the I²C/SMBus-compatible serial interface. A low-power, 5μA shutdown mode is controlled through an external logic input or the serial interface.

The MAX9729 consumes only 4.8mA of supply current, provides short-circuit and thermal-overload protection, and is specified over the -40°C to +85°C extended temperature range. The MAX9729 is available in a space-saving 28-pin thin QFN package (5mm x 5mm x 0.8mm).

Pin Configuration appears at end of data sheet.

Features

- ◆ DirectDrive Headphone Amplifier Eliminates Bulky DC-Blocking Capacitors
- ◆ 3:1 Input Multiplexer with Digital-Fade Circuitry
- ◆ Software-Enabled Bass Boost
- ◆ 32-Step Integrated Volume Control
- ◆ BEEP Input with Programmable Output Level
- ◆ Low Quiescent Current
- ◆ Industry-Leading Click-and-Pop Suppression
- ◆ I²C-Compatible 2-Wire Interface
- ◆ Short-Circuit Protection
- ◆ 1.8V to 3.6V Single-Supply Operation
- ◆ Available in Space-Saving, Thermally Efficient 28-Pin TQFN-EP (5mm x 5mm x 0.8mm)

Applications

Portable CD/DVD/MD
Players

Automotive Rear Seat
Entertainment (RSE)

Cell Phones

Flat-Panel TVs

MP3/PMP Players

Ordering Information

PART	PIN- PACKAGE	SLAVE ADDRESS*	PKG CODE
MAX9729ETI+	28 TQFN-EP**	101000_	T2855-5

Note: This device is specified over the -40°C to +85°C operating temperature range.

+ Denotes lead-free package.

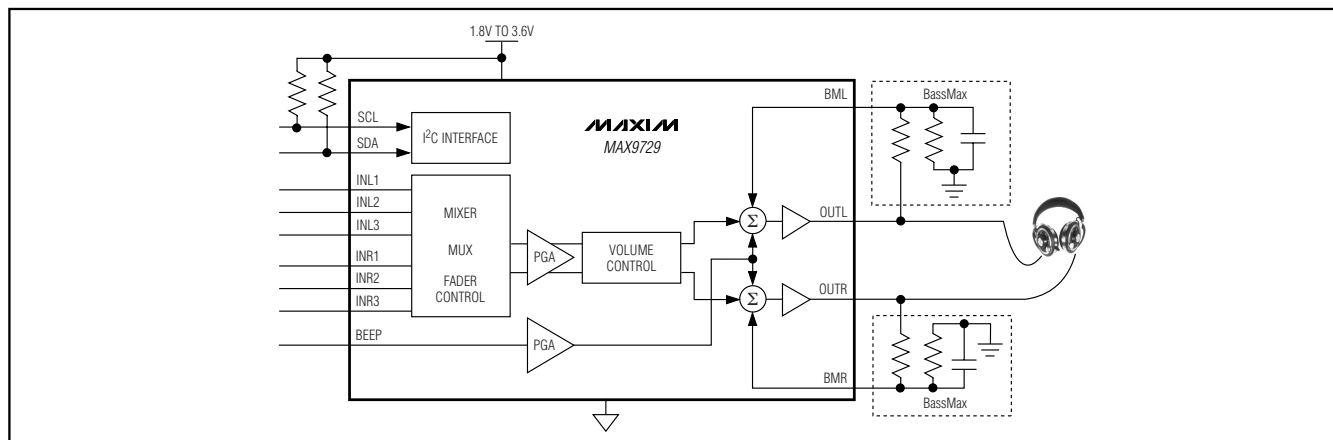

*Last digit of slave address is pin programmable.

**EP = Exposed pad.

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

ABSOLUTE MAXIMUM RATINGS

V_{DD}, PV_{DD} to PGND or SGND-0.3V to +4V
 V_{DD} to PV_{DD}Internally Connected
 PV_{SS} to SV_{SS}±0.3V
 SGND to PGND±0.3V
 C1P to PGND-0.3V to (V_{DD} + 0.3V)
 C1N to PGND(PV_{SS} - 0.3V) to +0.3V
 PV_{SS}, SV_{SS} to PGND+0.3V to -4V
 INL₋, INR₋, BEEP to SGND(SV_{SS} - 0.3V) to (V_{DD} + 0.3V)
 SDA, SCL, BEEP_EN to PGND-0.3V to +4V
 SHDN to PGND-0.3V to (V_{DD} + 0.3V)
 OUT₋ to PGND-3V to +3V
 BM₋ to SGND-2V to +2V
 Duration of OUT₋ Short Circuit to PGNDContinuous

Continuous Current Into/Out of:

V_{DD}, C1P, C1N, PGND, PV_{SS}, SV_{SS}, or OUT₋±0.85A
 All other pins±20mA

Continuous Power Dissipation (T_A = +70°C, multilayer board)

28-Pin Thin QFN (derate 28.6mW/°C above +70°C) 0.2286mW

Junction-to-Ambient Thermal Resistance (θ_{JA})

28-Pin TQFN35°C/W

Operating Temperature Range-40°C to +85°C

Junction Temperature+150°C

Storage Temperature Range-65°C to +150°C

OUT₋ ESD Protection (Human Body Model)±8kV

ESD Protection of All Other Pins±2kV

Lead Temperature (soldering, 10s)+300°C

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS (3V Supply)

(V_{DD} = PV_{DD} = $\overline{\text{SHDN}}$ = 3V, PGND = SGND = 0V, C1 = C2 = C3 = 1μF, BM₋ = 0V, maximum gain setting = 6dB, volume attenuation setting = -16dB (overall gain = -10dB), BassMax disabled. Load connected between OUT₋ and PGND where specified. THD+N measurement BW = 22Hz to 22kHz. T_A = T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = +25°C.) (Note 1)

Pin Description

PIN	NAME	FUNCTION
1	INR2	Right-Channel Input 2
2	INR3	Right-Channel Input 3
3	SGND	Signal Ground. Connect SGND to PGND at a single point on the PCB near the device.
4, 8, 15, 22	N.C.	No Connection. Not internally connected.
5	ADD	Slave Address Selection Input. Connect ADD to V_{DD} to set the device slave address to 1010001 or to PGND to set the device slave address to 1010000.
6	PVSS	Charge-Pump Output. Connect to SVSS.
7	SDA	Serial Data Input. Connect a pullup resistor greater than 500Ω from SDA to PV_{DD} .
9	C1N	Charge-Pump Flying Capacitor Negative Terminal. Connect a $1\mu F$ capacitor between C1P and C1N.
10	PGND	Power Ground. Connect PGND to SGND at a single point on the PCB near the device.
11	C1P	Charge-Pump Flying Capacitor Positive Terminal. Connect a $1\mu F$ capacitor between C1P and C1N.
12	SCL	Serial Clock Input. Connect a pullup resistor greater than 500Ω from SCL to PV_{DD} .
13	PVDD	Charge-Pump and Logic Power-Supply Input. Bypass PV_{DD} to PGND with a $1\mu F$ capacitor and connect to V_{DD} . PV_{DD} and V_{DD} are internally connected and should each have a $1\mu F$ bypass capacitor located as close to the device as possible.
14	SVSS	Headphone Amplifier Negative Power-Supply Input. Connect to PVSS and bypass with a $1\mu F$ capacitor to PGND.

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

Pin Description (continued)

PIN	NAME	FUNCTION
16	BMR	Right BassMax Input. Connect an external passive network between OUTR and BMR to apply bass boost to the right-channel output. See the <i>BassMax Gain-Setting Components</i> section. Connect BMR to SGND if BassMax is not used.
17	OUTR	Right Headphone Output
18	OUTL	Left Headphone Output
19	BML	Left BassMax Input. Connect an external passive network between OUTL and BML to apply bass boost to the left-channel output. See the <i>BassMax Gain-Setting Components</i> section. Connect BML to SGND, if BassMax is not used.
20	BEEP_EN	Beep Enable Input. Connect BEEP_EN to PVDD to enable the beep amplifier or to PGND to disable the beep amplifier.
21	$\overline{\text{SHDN}}$	Active-Low Shutdown Input. Drive $\overline{\text{SHDN}}$ low to disable the MAX9729. Connect $\overline{\text{SHDN}}$ to VDD while B7 in command register 0x00 is equal to 1 for normal operation (see <i>Command Registers</i> section).
23	VDD	Power-Supply Input. Bypass VDD to PGND with a 1 μ F capacitor and connect to PVDD. VDD and PVDD are internally connected and should each have a 1 μ F bypass capacitor located as close to the device as possible.
24	BEEP	Beep Input
25	INL1	Left-Channel Input 1
26	INL2	Left-Channel Input 2
27	INL3	Left-Channel Input 3
28	INR1	Right-Channel Input 1
EP	EP	Exposed Paddle. Connect EP to SVSS or leave unconnected.

Detailed Description

The MAX9729 stereo headphone amplifier features Maxim's patented DirectDrive architecture, eliminating the large output-coupling capacitors required by conventional single-supply headphone amplifiers. The MAX9729 consists of two 52mW Class AB headphone amplifiers, 3:1 stereo input multiplexer/mixer, two adjustable gain preamplifiers, a dedicated beep amplifier with independent gain control, hardware/software shutdown control, inverting charge pump, integrated 32-level volume control, BassMax circuitry, comprehensive click-and-pop suppression circuitry, and an I²C/SMBus-compatible interface (see the *Functional Diagram/Typical Operating Circuit*). A negative power supply (PVSS) is created internally by inverting the positive supply (PVDD). Powering the amplifiers from VDD and PVSS increases the dynamic range of the amplifiers to almost twice that of other single-supply amplifiers, increasing the total available output power.

An I²C/SMBus-compatible interface allows serial communication between the MAX9729 and a microcon-

troller. The MAX9729's slave address is programmed to one of two different values using the ADD input allowing two MAX9729 ICs to share the same bus (see Table 1). The internal command registers control the shutdown mode of the MAX9729, select/mix input signal sources, enable the BassMax circuitry, headphone and beep amplifier gains, and set the volume level (see Table 2). The MAX9729's BassMax circuitry improves audio reproduction by boosting the bass response of the amplifier, compensating for any low-frequency attenuation introduced by the headphone. External components set the MAX9729's overall gain allowing for custom gain settings (see the *BassMax Gain-Setting Components* section).

DirectDrive

Traditional single-supply headphone amplifiers have their outputs biased about a nominal DC voltage, typically half the supply, for maximum dynamic range. Large coupling capacitors are needed to block this DC bias from the headphone. Without these capacitors, a significant amount of DC current flows to the head-

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

phone, resulting in unnecessary power dissipation and possible damage to both headphone and headphone amplifier. In addition to the cost and size disadvantages, the DC-blocking capacitors required by conventional headphone amplifiers limit low-frequency response and can distort the audio signal.

Maxim's patented DirectDrive architecture uses a charge pump to create an internal negative supply voltage. This allows the MAX9729 headphone amplifier outputs to be biased about ground, almost doubling the dynamic range while operating from a single supply (see Figure 1). With no DC component, there is no need for the large DC-blocking capacitors. Instead of two large (up to 220 μ F) tantalum capacitors, the MAX9729 charge pump requires only two small 1 μ F ceramic capacitors, conserving board space, reducing cost, and improving the frequency response of the headphone amplifier. See the Output Power vs. Charge-Pump Capacitance and Load Resistance graph in the *Typical Operating Characteristics* for details of the possible capacitor sizes.

Charge Pump

The MAX9729 features a low-noise charge pump. The 610kHz switching frequency is well beyond the audio range, and does not interfere with the audio signals. This enables the MAX9729 to achieve an SNR of 99dB. The switch drivers feature a controlled switching speed that minimizes noise generated by turn-on and turn-off transients. Limiting the switching speed of the charge pump also minimizes di/dt noise caused by the parasitic bond wire and trace inductances.

Click-and-Pop Suppression

In conventional single-supply headphone amplifiers, the output-coupling capacitor is a major contributor of audible clicks and pops. The amplifier charges the coupling capacitor to its output bias voltage at startup. During shutdown, the capacitor is discharged. The charging and discharging results in a DC shift across the capacitor, which appears as an audible transient at the headphone speaker. Since the MAX9729 headphone amplifier does not require output-coupling capacitors, no audible transients occur.

Additionally, the MAX9729 features extensive click-and-pop suppression that eliminates any audible transient sources internal to the device. The Power-Up/Power-Down Waveform in the *Typical Operating Characteristics* shows that there are minimal transients at the output upon startup or shutdown.

In most applications, the preamplifier driving the MAX9729 has a DC bias of typically half the supply. The input-coupling capacitor is charged to the pream-

Figure 1. Traditional Amplifier Output vs. MAX9729 DirectDrive Output

plifier's bias voltage through the MAX9729's input resistor (R_{IN}) during startup. The resulting shift across the capacitor creates a voltage transient that must settle before the 50ms turn-on time has elapsed. Delay the rise of \overline{SHDN} by at least 4 time constants ($4 \times R_{IN} \times C_{IN}$) relative to the start of the preamplifier to avoid clicks/pops caused by the input filter.

Shutdown

The MAX9729 features a 5 μ A, low-power shutdown mode that reduces quiescent current consumption and extends battery life. Shutdown is controlled by the \overline{SHDN} logic input or software interface. Driving the \overline{SHDN} input low disables the drive amplifiers, bias circuitry, charge pump, and sets the headphone amplifier output resistance to 20k Ω . Similarly, the MAX9729 enters shutdown when bit seven (B7) in the command register, 0x00, is set to 0 (see the *Command Registers* section). \overline{SHDN} and B7 must be high to enable the MAX9729. The I²C/SMBus interface is active and the

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

contents of the command register are not affected when in shutdown. This allows the master device to write to the MAX9729 while in shutdown.

When a shutdown is activated, either hardware ($\overline{\text{SHDN}}$ pin) or software (I²C register), the volume is smoothly reduced, according to a constant slope ramp. Similarly, when a shutdown is deactivated, either hardware or software, the volume is smoothly increased, according to a constant slope ramp, until the volume programmed in the register file is reached.

BassMax (Bass Boost)

Typical headphones do not have a flat-frequency response. The small physical size of the diaphragm does not allow the headphone speaker to efficiently reproduce low frequencies. This physical limitation results in attenuated bass response. The MAX9729 includes a bass boost feature that compensates for the headphone's poor bass response by increasing the amplifier gain at low frequencies.

The DirectDrive output of the MAX9729 has more headroom than typical single-supply headphone amplifiers. This additional headroom allows boosting the bass frequencies without the output signal clipping.

Program the BassMax gain and cutoff frequency with external components connected between OUT_- and BM_- (see the *BassMax Gain-Setting Components* section and the *Functional Diagram/Typical Operating Circuit*). Use the I²C-compatible interface to program the command register to enable/disable the BassMax circuit.

BM_- is connected to the noninverting input of the output amplifier when BassMax is enabled. BM_- is pulled to SGND when BassMax is disabled. The typical application of the BassMax circuit involves feeding a low-pass-filtered version of the output signal back to the

amplifier. This is realized using positive feedback from OUT_- to BM_- . Figure 2 shows the connections needed to implement BassMax.

Maximum Gain Control

The MAX9729 features eight different programmable maximum gain settings ranging from +3.5dB to +26dB (see Table 8). Bits [2:0] in command register 0x01 control the maximum gain setting (AV_{MAX}).

Volume Control

The MAX9729 includes a 32-level volume control that adjusts the total voltage gain of the headphone amplifier according to the values of bits [4:0] in the 0x00 command register. With BassMax disabled, the total voltage gain of the MAX9729 is equal to:

$$\text{AV}_{\text{TOTAL}} = \text{AV}_{\text{MAX}} - \text{ATTEN}(\text{dB})$$

where AV_{TOTAL} is the total voltage gain in dB, AV_{MAX} is the maximum gain setting in dB, and ATTEN is the volume attenuation in dB.

Tables 5a, 5b, 5c show all the possible volume attenuation settings and the resulting AV_{TOTAL} with BassMax disabled. Figure 8 shows the volume control transfer function. Mute attenuation is typically better than 100dB when driving a 32 Ω load. To perform smooth-sounding volume changes, step through all intermediate volume settings at a rate of approximately 2ms per step when a volume change occurs.

Automatic Volume Ramping During Mode Transitions and Input Source Selection

The MAX9729 implements an automatic volume ramp-up/ramp-down function when exiting/entering shutdown and when selecting different input signal paths with the internal 3:1 multiplexer. The automatic volume ramp-up/ramp-down function steps through each intermediate volume setting at a rate of 1.5ms per step allowing for smooth sounding volume transitions. When exiting/entering shutdown, the volume ramp-up/ramp-down function is implemented regardless of whether the shutdown command is initiated by an I²C command or the $\overline{\text{SHDN}}$ input. When exiting shutdown, the volume is ramped up to the value stored in register 0x00 (see Table 2). When selecting a new input signal path with the multiplexer, the MAX9729 first ramps down the volume, selects the new input source, and then ramps the volume back up to the value stored in register 0x00. This prevents any audible clicks and pops due to abrupt changes in signal amplitude when selecting a different input signal source.

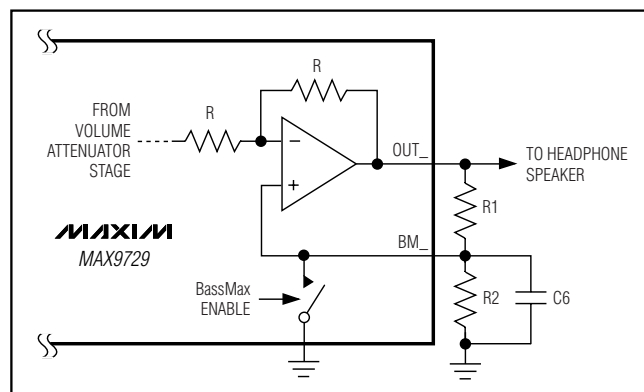

Figure 2. BassMax External Connections

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

BEEP Input

The MAX9729 features a BEEP input with eight different attenuation settings (see Table 6). The BEEP input is useful for applications requiring the routing of a system alert signal to the stereo audio path. The attenuation value of the BEEP input is set by bits [7:5] in the 0x01 command register (see Tables 2 and 6). The attenuation settings of the BEEP input are independent of the volume settings stored in register 0x00 (see Table 2). The BEEP input is enabled when BEEP_EN is connected to V_{DD} and disabled when driven low. When BEEP_EN is high, the selected INL_ and INR_ inputs are disconnected from the signal path and the BEEP input signal is routed to both headphone outputs after being attenuated by the value set by bits [7:5] in register 0x01. When BEEP_EN is low, the BEEP input is disconnected from the signal path and the selected INL_ and INR_ inputs are reconnected.

Input Multiplexer/Mixer

The MAX9729 includes a stereo 3:1 multiplexer/mixer, allowing selection and mixing of three different stereo input sources. Bits [6:5] in register 0x00 control the selection/mixing of the input signal sources (see Tables 2 and 4). When all three stereo inputs are selected (Bits [6:5] = 11), the stereo signals are summed (mixed) together and connected to the signal path. The MAX9729 implements the automatic volume ramping function when an input source change occurs to ensure smooth sounding transitions. Clipping may occur if three high level signals are summed. Reprogram the preamplifier maximum gain setting to compensate.

Serial Interface

The MAX9729 features an I²C/SMBus-compatible 2-wire serial interface consisting of a serial data line (SDA) and

a serial clock line (SCL). SDA and SCL facilitate bidirectional communication between the MAX9729 and the master at clock rates up to 400kHz. Figure 3 shows the 2-wire interface timing diagram. The MAX9729 is a transmit/receive slave-only device, relying upon a master device to generate the clock signal. The master device, typically a microcontroller, initiates data transfer on the bus and generates SCL to permit that transfer.

A master device communicates to the MAX9729 by transmitting the slave address with the Read/Write (R/W) bit followed by the data word. Each transmit sequence is framed by a START (S) or REPEATED START (Sr) condition and a STOP (P) condition. Each word transmitted over the bus is 8 bits long and is always followed by an acknowledge or not acknowledge clock pulse.

The MAX9729 SDA line operates as both an input and an open-drain output. A pullup resistor, greater than 500Ω, is required on the SDA bus. The MAX9729 SCL line operates as an input only. A pullup resistor, greater than 500Ω, is required on SCL unless the MAX9729 is operating in a single-master system where the master device has a push-pull SCL output. Series resistors in line with SDA and SCL are optional. Series resistors protect the digital inputs of the MAX9729 from high-voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus signals.

Bit Transfer

One data bit is transferred during each SCL cycle. The data on SDA must remain stable during the high period of the SCL pulse since changes in SDA while SCL is high are control signals (see the *START and STOP Conditions* section). SDA and SCL idle high when the I²C bus is not busy.

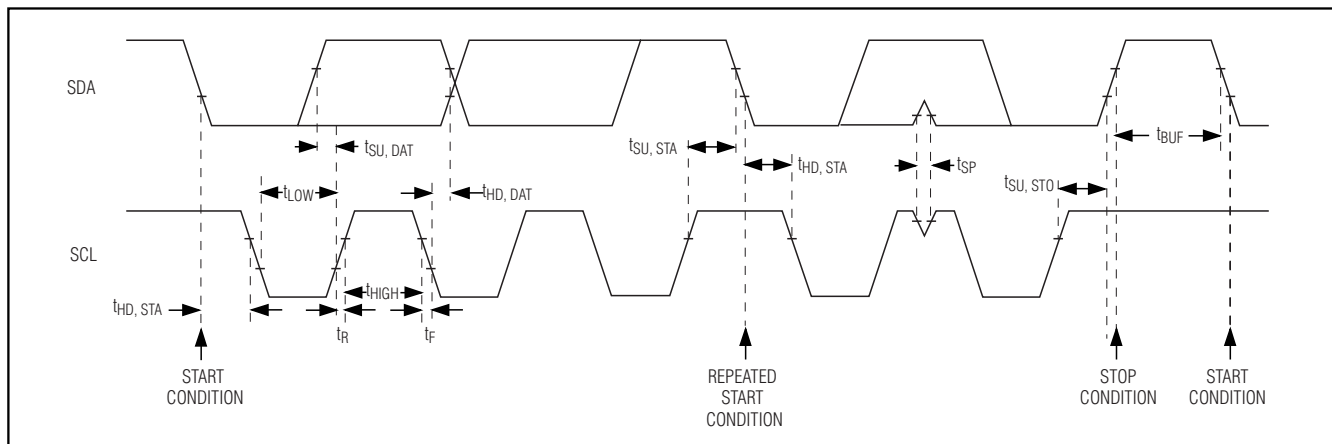

Figure 3. 2-Wire Serial-Interface Timing Diagram

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

Figure 4. START, STOP, and REPEATED START Conditions

START and STOP Conditions

SDA and SCL idle high when the bus is not in use. A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA while SCL is high (see Figure 4). A START condition from the master signals the beginning of a transmission to the MAX9729. The master terminates transmission, and frees the bus, by issuing a STOP condition. The bus remains active if a REPEATED START condition is generated instead of a STOP condition.

Early STOP Conditions

The MAX9729 recognizes a STOP condition at any point during data transmission except if the STOP condition occurs in the same high clock pulse as a START condition. At least one clock pulse must separate any START and STOP conditions.

Slave Address

The slave address of the MAX9729 is pin programmable using the ADD input to one of two different values (see Table 1). The slave address is defined as the 7 most significant bits (MSBs) of the serial data transmission. The first byte of information sent to the MAX9729 after the START condition must contain the slave address and R/\overline{W} bit. R/\overline{W} bit indicates whether the master is writing to or reading from the MAX9729 ($R/\overline{W} = 0$ selects

Table 1. MAX9729 Slave Address with R/\overline{W} Bit

ADD	MAX9729 SLAVE ADDRESS							R/\overline{W}
	A6 (MSB)	A5	A4	A3	A2	A1	A0	
GND	1	0	1	0	0	0	0	0
VDD	1	0	1	0	0	0	1	0

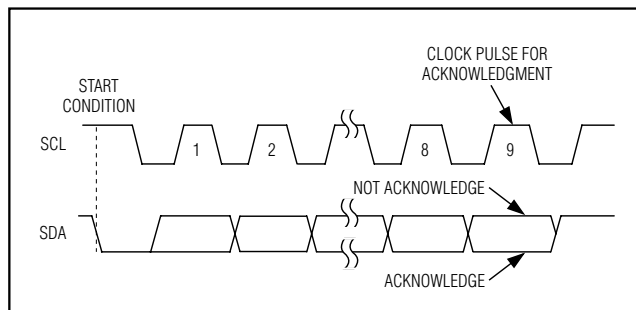

Figure 5. Acknowledge

the write condition, $R/\overline{W} = 1$ selects the read condition). After receiving the proper address, the MAX9729 issues an ACK by pulling SDA low for one clock cycle.

Acknowledge

The acknowledge bit (ACK) is the ninth bit attached to any byte transmitted over the serial interface (see Figure 5). ACK is always generated by the receiving device. The MAX9729 generates an ACK when receiving a slave address or data by pulling SDA low during the ninth clock period. The SDA line must remain stable and low during the high period of the ACK clock pulse. When transmitting data, the MAX9729 waits for the receiving device to generate an ACK. Monitoring ACK allows detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

Write Data Format

A write to the MAX9729 includes transmission of a START condition, the slave address with the R/\overline{W} bit set to 0 (see Table 1), one or two command bytes to configure the command registers, and a STOP condition. Figure 6a illustrates the proper data transmission for writing to register 0x00 in a single frame. Figure 6b illustrates the proper data transmission for writing to both registers 0x00 and 0x01 in a single frame.

As shown in Figures 6a and 6b, the MAX9729 communicates an ACK after each byte of information is received. The MAX9729 latches each command byte into the respective command registers after an ACK is communicated. The master device terminates the write data transmission by issuing a STOP condition.

When writing to register 0x01, register 0x00 must be written to first in the same data frame as shown in Figure 6b. In other words, when updating register 0x01 both registers must be written to.

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

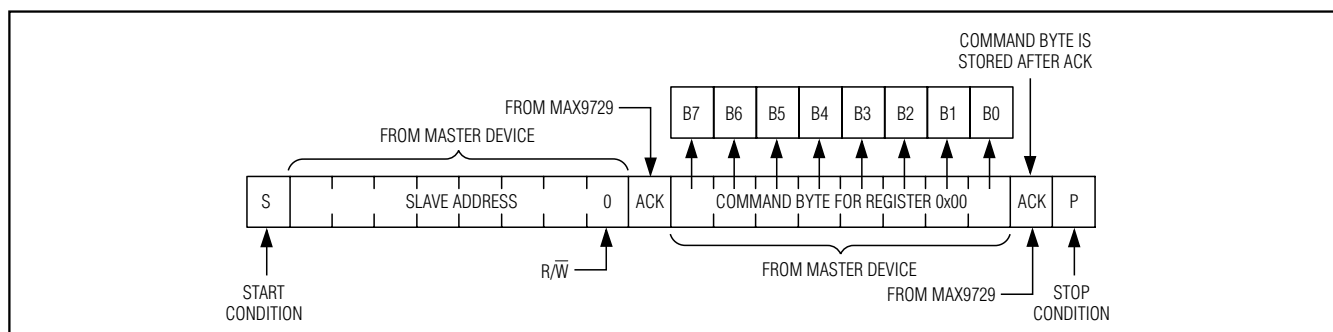

Figure 6a. Write Data Format for Writing to Register 0x00 Only

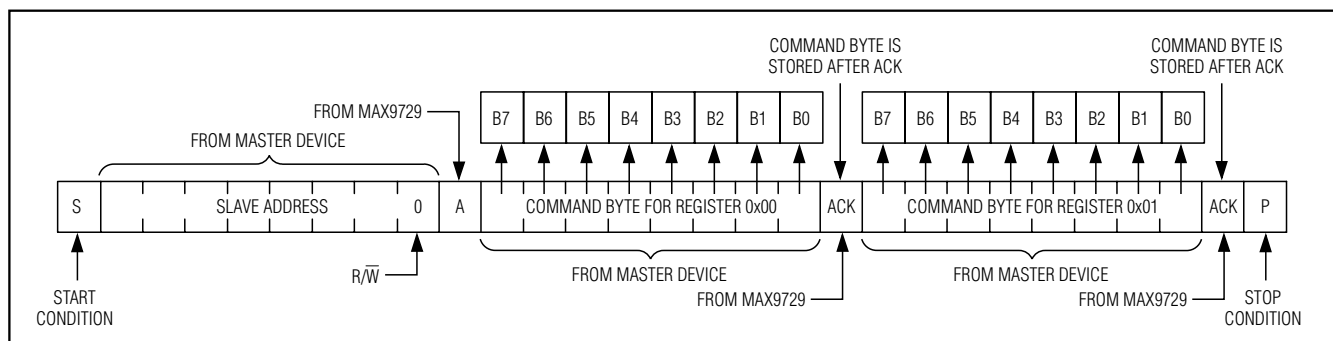

Figure 6b. Write Data Format for Writing to Registers 0x00 and 0x01

Read Data Format

A read from the MAX9729 includes transmission of a START condition, the slave address with the R/W bit set to 1, one or two bytes of register data sent by the MAX9729, and a STOP condition. Once the MAX9729 acknowledges the receipt of the slave address and R/W bit, the data direction of the SDA line reverses and the MAX9729 writes the contents of the command register 0x00 and 0x01 to the bus in that order. Each byte sent by the MAX9729 should be acknowledged by the master device unless the byte is the last data byte of the transmission, in which case, the master device should communicate a not acknowledge (NACK). After the NACK is communicated, the master device terminates the read data transmission by issuing a STOP condition. Figure 7a illustrates the proper data transmission for reading the contents of register 0x00. Figure 7b illustrates the proper data transmission for reading the contents of both registers 0x00 and 0x01 in a single frame. Data sent by the MAX9729 is valid on the rising edge of SCL.

When reading register 0x01, register 0x00 must be read first in the same data frame as shown in Figure 7b.

In other words, when reading register 0x01 both registers must be read.

Command Registers

The MAX9729 utilizes two command registers to enable/disable shutdown, control the multiplexer/mixer, set the volume, set the BEEP input attenuation, enable/disable BassMax, and set the maximum gain. Table 2 describes the function of the bits contained in the command registers.

Set B7 to 0 in register 0x00 to shut down the MAX9729. The MAX9729 exits shutdown when B7 is set to 1 provided $\overline{\text{SHDN}}$ is high. $\overline{\text{SHDN}}$ must be high and B7 must be set to 1 for the MAX9729 to operate normally (see Table 3).

Bits [6:5] in register 0x00 control the input multiplexer/mixer. Select the desired input path and enable mixing of all three stereo input sources with these bits (see Table 4).

Adjust the MAX9729's volume with bits [4:0] in register 0x00. The volume is adjustable to one of 32 steps ranging from full mute to the maximum gain set by bits [B2:B0] in register 0x01. Tables 5a, 5b, 5c list all the possible volume settings and resulting total voltage

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

gains for the MAX9729. Figure 8 shows the volume control transfer function for the MAX9729.

Use bits [B7:B5] in register 0x01 to set the BEEP input attenuation. The BEEP input attenuation is adjustable to one of eight different values ranging from -10dB to -56dB (see Table 6).

Set B3 in register 0x01 to 1 to enable BassMax (see Table 7). The output signal's low-frequency response will be boosted according to the external components connected between OUT₋ and BM₋. See the *BassMax Gain-Setting Components* section for details on choosing the external components.

Use bits [2:0] in register 0x01 to set the maximum gain of the MAX9729 to one of eight different values ranging from +3.5dB to +26dB (see Table 8). The maximum gain setting in conjunction with the volume setting determines the overall voltage gain of the MAX9729 (see Tables 5a, 5b, 5c).

Power-On Reset

The MAX9729 features internal power-on reset (POR) circuitry that initializes the device upon power-up. The contents of the MAX9729's command registers at power-on are shown in Table 9.

Applications Information

Power Dissipation and Heat Sinking

Linear power amplifiers can dissipate a significant amount of power under normal operating conditions. The maximum power dissipation for each package is given in the *Absolute Maximum Ratings* section under Continuous Power Dissipation or can be calculated by the following equation:

$$P_{D(MAX)} = \frac{T_{J(MAX)} - T_A}{\theta_{JA}}$$

where $T_{J(MAX)}$ is +150°C, T_A is the ambient temperature, and θ_{JA} is the reciprocal of the derating factor in °C/W as specified in the *Absolute Maximum Ratings* section. For example, θ_{JA} for the thin QFN package is +35°C/W.

If the power dissipation exceeds the rated package dissipation, reduce V_{DD} , increase load impedance, decrease the ambient temperature, or add heatsinking. Large output, supply, and ground traces decrease θ_{JA} , allowing more heat to be transferred from the package to surrounding air.

Output Dynamic Range

Dynamic range is the difference between the noise floor of the system and the output level at 1% THD+N. It is essential that a system's dynamic range be known before setting the maximum output gain. Output clipping will occur if the output signal is greater than the dynamic range of the system. The DirectDrive architecture of the MAX9729 has increased dynamic range (for a given V_{DD}) compared to other single-supply amplifiers. Due to the absolute maximum ratings of the MAX9729 and to limit power dissipation, the MAX9729 includes internal circuitry that limits the output voltage to approximately ±2.5V.

Use the THD+N vs. Output Power graph in the *Typical Operating Characteristics* to identify the system's dynamic range. Find the output power that causes 1% THD+N for a given load. This point will indicate what output power causes the output to begin to clip. Use the following equation to determine the peak-to-peak output voltage that causes 1% THD+N for a given load:

$$V_{OUT_ (P-P)} = 2\sqrt{2(P_{OUT_1\%} \times R_L)}$$

where $P_{OUT_1\%}$ is the output power that causes 1% THD+N, R_L is the load resistance, and $V_{OUT_ (P-P)}$ is the peak-to-peak output voltage. Determine the total voltage gain (A_{V_TOTAL}) necessary to attain this output voltage based on the maximum peak-to-peak input voltage ($V_{IN_ (P-P)}$):

$$A_{V_TOTAL} = \frac{V_{OUT_ (P-P)}}{V_{IN_ (P-P)}}$$

The A_{V_TOTAL} setting is determined by the maximum voltage gain setting, volume setting, and bass boost gain if BassMax is enabled (see the *Maximum Gain Control, Volume Control, and BassMax Gain-Setting Components* sections).

UVLO

The MAX9729 features an undervoltage lockout (UVLO) function that prevents the device from operating if the supply voltage is less than 1.65V. This feature ensures proper operation during brownout conditions and prevents deep battery discharge. Once the supply voltage exceeds the UVLO threshold, the MAX9729 charge pump is turned on, the amplifiers are powered (provided that \overline{SHDN} is high), and the command registers are reset to their POR values (see Table 9).

Component Selection

Charge-Pump Capacitor Selection

Use ceramic capacitors with a low ESR for optimum performance. For optimal performance over the extended temperature range, select capacitors with an X7R dielectric.

1	1	1	-56

BEEP level referenced to a 3V BEEP input.

Charge-Pump Flying Capacitor (C1)

The charge-pump flying capacitor connected between C1N and C1P affects the charge pump's load regulation and output impedance. Choosing too small a flying capacitor degrades the MAX9729's ability to provide sufficient current drive and leads to a loss of output voltage. Increasing the value of the flying capacitor improves load regulation and reduces the charge-pump output impedance. See the Output Power vs. Charge-Pump Capacitance and Load Resistance

Table 7. BassMax Control (Register 0x01)

1	0	1	22
1	1	0	24
1	1	1	26

graph in the *Typical Operating Characteristics*. Place C1 physically close to C1P and C1N. Use a 1μF capacitor for C1 in most applications.

Charge-Pump Hold Capacitor (C2)

The hold capacitor's value and ESR directly affect the ripple at PVSS. Ripple is reduced by increasing the value of the hold capacitor. Choosing a capacitor with lower ESR reduces ripple and output impedance. Lower capacitance values can be used in systems with low maximum output power levels. See the Output Power vs. Charge-Pump Capacitance and Load Resistance graph in the *Typical Operating Characteristics*. C2 should be equal to the value of C1. Place C2 physically close to PVSS and SVSS. Connect PVSS and SVSS together at C2. Use a 1μF capacitor for C2 in most applications.

PVDD Bypass Capacitor (C3)

The PVDD bypass capacitor lowers the output impedance of the power supply and reduces the impact of the MAX9729's charge-pump switching transients. C3 should be greater than or equal to C1. Place C3 physically close to PVDD.

Stereo Headphone Amplifier with BassMax, Volume Control, and Input Mux

Input-Coupling Capacitor

The AC-coupling capacitor (C_{IN}) and input resistor (R_{IN}) form a highpass filter that removes any DC bias from an input signal. See the *Functional Diagram/Typical Operating Circuit*. C_{IN} prevents any DC components from the input signal source from appearing at the amplifier outputs. The -3dB point of the highpass filter, assuming zero source impedance due to the input signal source, is given by:

$$f_{-3dB} = \frac{1}{2\pi \times R_{IN} \times C_{IN}} \text{ (Hz)}$$

Choose C_{IN} such that f_{-3dB} is well below the lowest frequency of interest. Setting f_{-3dB} too high affects the amplifier's low-frequency response. Use capacitors with low-voltage coefficient dielectrics. Aluminum electrolytic, tantalum, or film dielectric capacitors are good choices for AC-coupling capacitors. Capacitors with high-voltage coefficients, such as ceramics (non-C0G dielectrics), can result in increased distortion at low zero frequencies. If a ceramic capacitor is selected due to board space or cost constraints, use the largest package possible to minimize voltage coefficient effects. In addition, use X7R dielectrics as opposed to X5R, Y5V, or Z5U.

BassMax Gain-Setting Components

The bass boost, low-frequency response when BassMax is enabled, is set by the ratio of $R1$ to $R2$ (see Figure 2), by the following equation:

$$A_{V_BOOST} = 20 \times \log \frac{R1 + R2}{R1 - R2} \text{ (dB)}$$

where A_{V_BOOST} is the gain boost, in dB, at low frequencies. A_{V_BOOST} is added to the gain realized by the maximum gain setting and the volume setting. The total gain at low frequencies is equal to:

$$A_{V_TOTAL_BM} = A_{V_MAX} - ATTEN + A_{V_BOOST} \text{ (dB)}$$

where $A_{V_TOTAL_BM}$ is the total voltage gain at low frequencies in dB, A_{V_MAX} is the maximum gain setting in dB, and $ATTEN$ is the volume attenuation in dB. To maintain circuit stability, the ratio:

$$\frac{R2}{R1 + R2}$$

must not exceed 1/2. A ratio equaling 1/3 is recommended. The switch that shorts BM_{-} to $SGND$, when BassMax is disabled, can have an on-resistance as high as 300Ω.

Table 10. BassMax Gain Examples, $R1 = 47k\Omega$

R2 (kΩ)	A _{V_BOOST} (dB)
39	20.6
33	15.1
27	11.3
22	8.8
15	5.7
10	3.7

Choose a value for $R1$ that is greater than 40kΩ to ensure that positive feedback is negligible when BassMax is disabled. Table 10 contains a list of $R2$ values, with $R1 = 47k\Omega$, and the corresponding low-frequency gain boost values.

The low-frequency boost attained by the BassMax circuit is added to the gain realized by the maximum gain setting and volume setting. Select the BassMax gain so that the output signal will remain within the dynamic range of the MAX9729. Output signal clipping will occur at low frequencies if the BassMax gain boost is excessively large. See the *Output Dynamic Range* section.

Capacitor $C4$ forms a pole and a zero according to the following equations:

$$f_{POLE} = \frac{R1 - R2}{2\pi \times C6 \times R1 \times R2} \text{ (Hz)}$$

$$f_{ZERO} = \frac{R1 + R2}{2\pi \times C6 \times R1 \times R2} \text{ (Hz)}$$

f_{POLE} is the frequency at which the gain boost begins to roll off. f_{ZERO} is the frequency at which the bass boost gain no longer affects the transfer function. At frequencies greater than or equal to f_{ZERO} , the gain set by the maximum gain setting and the volume control attenuation dominate. Table 11 contains a list of capacitor values and the corresponding poles and zeros for a given DC gain. See Figure 9 for an example of a gain profile using BassMax.

Layout and Grounding

Proper layout and grounding are essential for optimum performance. Connect $PGND$ and $SGND$ together at a single point (star ground point) on the PCB near the MAX9729. Connect $PVSS$ and $SVSS$ together at $C2$. Place $C2$ physically close to $PVSS$ and $SVSS$ and connect it to $PGND$. Bypass $PVDD$ to $PGND$ with $C3$. Connect $C3$ as close to $PVDD$ as possible. Bypass VDD to $SGND$ with a 1μF capacitor. Place the VDD bypass

C6 (nF)	f _{POLE} (Hz)	f _{ZERO} (Hz)
100	38	106
82	47	130
68	56	156
56	68	190
47	81	230
22	174	490
10	384	1060

capacitor as close to V_{DD} as possible. Route PGND and all traces that carry switching transients away from SGND and the audio signal path. Route digital signal traces away from the audio signal path. Make traces perpendicular to each other when routing digital signals over or under audio signals.

The thin QFN package features an exposed paddle that improves thermal efficiency. **Ensure that the exposed paddle is electrically isolated from PGND, SGND, and V_{DD}. Connect the exposed paddle to SV_{SS} when the board layout dictates that the exposed paddle cannot be left unconnected.**
