

### General Description

The AAT3526/7/8 PowerManager™ products are members of AATI's Total Power Management IC™ (TPMIC™) product family. These microprocessor reset circuits are ideal for monitoring voltage supplies in portable systems, where extended battery life is critical. They provide a low cost, reliable solution by eliminating external components. The AAT3526/7/8 products operate by monitoring the system power supply voltage. When the input voltage drops below a fixed threshold, the device asserts a reset signal for a minimum of 150ms after  $V_{CC}$  has risen back above the fixed threshold. They are guaranteed to operate down to 1.2V and designed to ignore fast line transients appearing on  $V_{CC}$ . The AAT3526/7/8 series is available with three output stage versions: AAT3526 push-pull active low output, AAT3527 push-pull active high output and AAT3528 open drain active low output. The quiescent supply current is extremely low, typically 1µA, making this device ideal for portable battery operated equipment.

The AAT3526/7/8 are available in a 4 pin SOT143 package and are specified over -40° to 85°C operating temperature range.

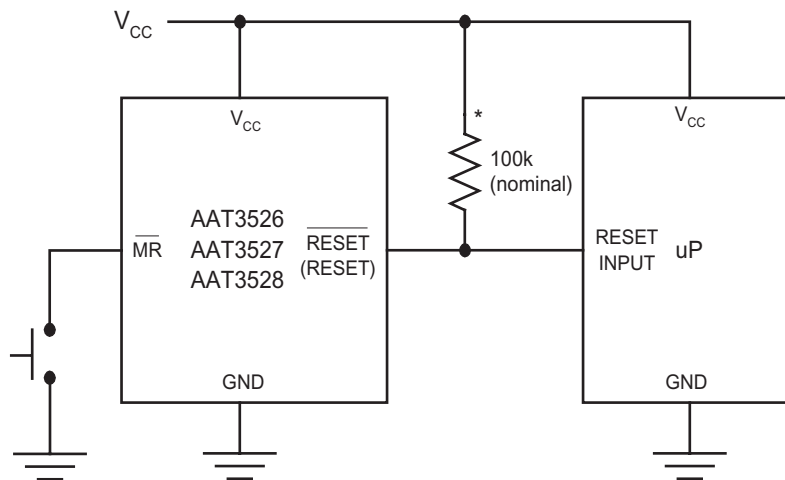

### Features

- 1.2V to 5.5V Input voltage range
- Operation down to 1.2V
- Extremely low quiescent current: less than 2µA
- High accuracy detection threshold: ±1.5%
- Monitor Power Supply Voltages
- Fixed thresholds from 2.2V to 4.6V
- Minimum 150ms reset pulse width with fast delay time <20µs
- Debounced Manual Reset Input
- Available output configurations:
  - Open-drain output
  - CMOS active high output
  - CMOS active low output
- Temp range -40 to 85°C
- 4 pin SOT143 package

### Applications

- Notebook Computers
- Cell Phones
- Portable Electronics
- Embedded Systems
- Intelligent Instruments

## Pin Descriptions

### AAT3526, 3527, 3528 (SOT143)

Pin #	Symbol	Function
1	GND	Ground connection
2	RESET (AAT3527)	RESET output remains high while $V_{CC}$ is below the reset threshold and remains so for a minimum of 150ms after $V_{CC}$ raises above the reset threshold.
	$\overline{\text{RESET}}$ (AAT3526, AAT3528)	$\overline{\text{RESET}}$ output remains low while $V_{CC}$ is below the reset threshold and remains so for a minimum of 150ms after $V_{CC}$ raises above the reset threshold
3	$\overline{\text{MR}}$	Manual Reset active low input. A logic low signal on $\overline{\text{MR}}$ asserts a reset condition. Asserted reset continues as long as $\overline{\text{MR}}$ is low and for a minimum of 150ms after $\overline{\text{MR}}$ returns high
4	Vcc	Supply Voltage (+1.2V to +5.5V)

**Functional Block Diagram**

**Functional Description**

**General**

During start-up, the reset pin on a microprocessor ensures that it is fully reset and starts up in a known condition. The AAT3526/7/8 series of microprocessor reset devices monitor the supply voltage to a

microprocessor and assert a reset signal whenever the  $V_{CC}$  voltage falls below a factory programmed threshold. This threshold is accurate within +/-1.5% at 25°C and within +/- 2.5% over the entire operating temperature range. The reset signal remains asserted for a minimum of 150ms after  $V_{CC}$  has risen above the threshold as shown in Figure 1.

### Applications Information

#### Reset Output Options

The AAT3528 has an active low open drain output and the AAT3526/7 have a push-pull output. The AAT3528 may be used in multiple voltage systems, with an external pull-up resistor. This allows the AAT3528 to interface to microprocessors with higher supply voltages up to 5.5V (Figure 2). In the event of a power down or brown-out condition the reset signal remains valid until the  $V_{CC}$  drops below 1.2V. To ensure validity down to ground an external 100k $\Omega$  resistor should be connected between the RESET output and GND.

#### Manual Reset Input

A logic low signal on  $\overline{MR}$  asserts a reset condition. Reset continues to be asserted as long as  $\overline{MR}$  is low and for a minimum of 150ms after  $\overline{MR}$  returns high. This input is internally pulled up to  $V_{CC}$  via a 20k $\Omega$  resistor, so leaving the pin unconnected is acceptable if manual reset function is not needed. The  $\overline{MR}$

input is internally debounced which allows use of a mechanical switch. It should be a normally-open momentary switch connected from  $\overline{MR}$  to GND. Additionally, the  $\overline{MR}$  pin can be driven from TTL, CMOS, or open drain logic outputs.

#### Supply Voltage Transient Behavior

In some cases fast negative transients of short duration can appear on the  $V_{CC}$  power supply. The AAT3526/7/8 series devices provide some immunity to line transients which can generate invalid reset pulses. Figure 1 shows typical behavior to short duration pulses versus RESET comparator overdrive. As shown in the Maximum Transient Duration vs. Reset Threshold Overdrive graph, when the transient voltage becomes larger, the time allowed before asserting a reset becomes shorter. e.g. typically a transient of 100mV below the reset threshold would have to present for more than 50 $\mu$ s to cause a reset. Immunity can be increased by the addition of a small by-pass capacitor of 0.1 $\mu$ F connected as close to the  $V_{CC}$  pin as possible.
