

CAR RADIO SIGNAL PROCESSOR

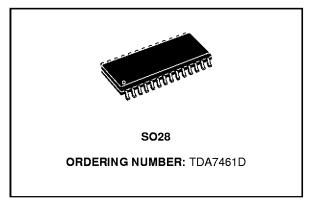

- HIGH PERFORMANCE SIGNAL PROCES-SOR FOR CAR RADIO SYSTEMS
- DEVICE INCLUDES AUDIO PROCESSOR, STEREO DECODER, NOISEBLANKER AND MULTIPATH DETECTOR
- NO EXTERNAL COMPONENTS REQUIRED
- FULLY PROGRAMMABLE VIA I²C BUS
- LOW DISTORTION
- LOW NOISE

DESCRIPTION

The TDA7461 is a high performance signal processor specifically designed for car radio applications.

The device includes a complete audioprocessor and a stereo decoder with noiseblanker, stereoblend and all signal processing functions necessary for state-of-the-art as well as future car radio systems.

Switched-capacitors design technique allows to obtain all these features without external compo-

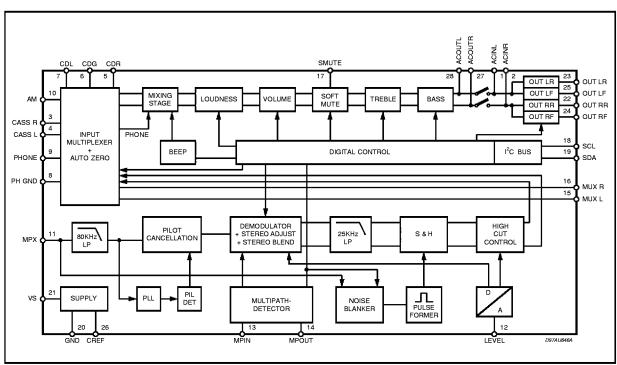

nents or adjustments. This means that higher quality and reliability walks alongside an overall cost saving.

The CSP is fully programmable by I²C bus interface allowing to customize key device parameters and especially filter characteristics.

The BICMOS process combined with the optimized signal processing assure low noise and low distortion performances.

AUDIO PROCESSOR PART

Input Multiplexer

- Fully differential or quasi-differential CD and cassette stereo input
- AM mono or stereo input
- Phone differential or single ended input
- Internal beep with 2 frequencies (selectable)
- Mixable phone and beep signals

Loudness

- Second order frequency response
- Programmable center frequency and quality factor
- 15 x 1dB steps
- Selectable flat-mode (constant attenuation)

Volume control

- 1dB attenuator
- Max. gain 20dB
- Max. attenuation 79dB
- Soft-step gain control

Bass Control

- 2nd order frequency response
- Center frequency programmable in 4(5) steps
- DC gain programmable
- 7 x 2dB steps

Treble Control

- 2nd order frequency response
- Center frequency programmable in 4 steps
- 7 x 2dB steps

Speaker Control

 4 independent speaker controls (1dB steps control range 50dB)

Mute Functions

- Direct mute
- Digitally controlled softmute with 4 programmable time constants

ELECTRICAL CHARACTERISTICS (Vs = 9V; $T_{amb} = 25^{\circ}C$; $R_{L} = 10 \text{K}\Omega$; all gains = 0dB; f = 1 KHz; unless otherwise specified).

DESCRIPTION OF THE AUDIOPROCESSOR PART

Programmable Input Matrix

The programmable input matrix of the TDA7461 offers several possibilities to adapt the audioprocessor to the desired application. In to the standard application we have:

- CD quasi differential
- Cassette stereo
- Phone differential
- AM mono
- Stereodecoder input.

The input matrix can be configured by only 2 bits:

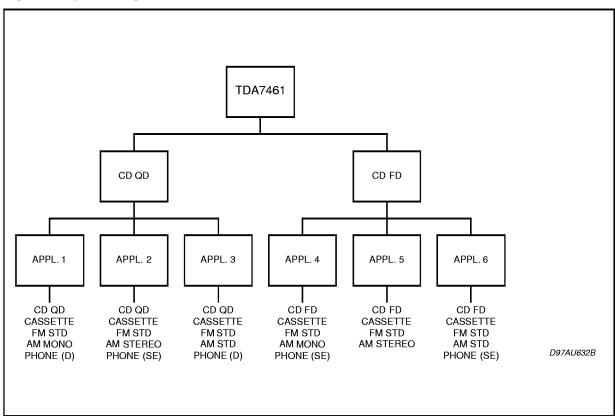

bits 3 and 4 of subaddress 0. Basically the bit of subaddress 13 is fixed by the application and has to be programmed only once at the startup of the IC.

For many configurations the two bits are also fixed during one application (e.g. the standard application) and a change of the input source can be done by loading the first three bits of subaddress 0.

In other configurations for some sources a programming of bit 3 and 4 of subaddress 0 is necessary in addition to the three source selection bits. In every case only the subaddress 0 has to be changed to switch from one source to another.

The following picture shows the input and source programming flow:

Figure 1. Input Configuration Tree

 $\textbf{Note:} \ \text{in AMSTD configuration the AM monosignal is lead through the FM stereodecoder part to use its additional filters and high-cut function.}$

| | | PIN N | UMBER | | | |
|----------|--------------------|----------|---------|--------|-------------------|--|
| Appl. No | 4 | 6 | 7 | 8 | Prog | ramming ¹⁾ |
| 1 | CDGND | Phonegno | Phone | АМмоно | Startup: | 0/xxx11xxx |
| 2 | CD _{GND} | Phonegno | AMRIGHT | AMLEFT | Startup: | 0/xxxx1xxx |

| | | | | | FM AM | 0/xxx10100 0/xxx00011 |
| 6 | CDR _{GND} | CDLGND | Phone | AMstd | Startup: | 0/xxxx0xxx |
| | | | | | FM AM Phone | 0/xxx10100 0/xxx00100 0/xxx10010 |

¹⁾ Syntax 0/xxx11100 means: SUBADDR ESS = 0 - DATA BYTE = xxx11100 (x - don't care)

How to find the right input configuration

The best way to come to the desired configuration may be to go through the application tree from the top to the bottom while making the specific decisions.

This way will lead to one of the six possible applications. Then take the number of the application and go into the pinning table. Here you will find the special pinout as well as the special programming codes for selecting sources.

For example in Appl. 6 the TDA7461 has to be configured while startup with the databyte 0/xxxx0xxx.

To select the FM, AM or phone source the last five significant bits of subaddress 0 have to be changed, for any other source the last three bits are sufficient (see data byte specification).

Input stages

Most of the input circuits are the same as in preceding ST audioprocessors with exception of the CD inputs (see figure 2).

In the meantime there are some CD players in the market having a significant high source impedance which affects strongly the commonmode rejection of the normal differential input stage. The additional buffer of the CD input avoids this drawback and offers the full commonmode rejection even with those CD players.

The TDA7461 can be configured with an additional input; if the AC coupling before the speaker stage is not used (bit 7 in subaddress 5 set to "1") ACINL and ACINR pins can be used as an additional stereo input.

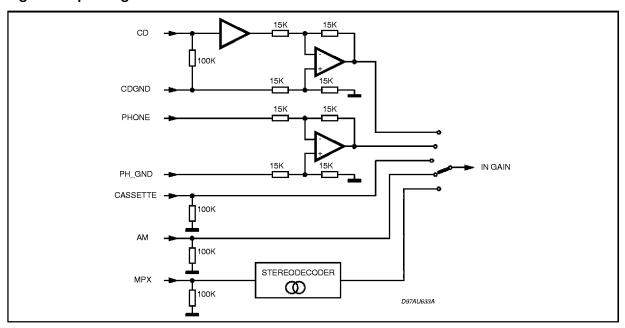

AutoZero

In order to reduce the number of pins there is no AC coupling between the In-Gain and the following stage, so that any offset generated by or before the In-Gain stage would be transferred or even amplified to the output.

To avoid that effect a special offset cancellation stage called AutoZero is implemented.

To avoid audible clicks the audioprocessor is muted before the loudness stage during this time. In some cases, for example if the μP is executing a refresh cycle of the $l^2 C$ bus programming, it is not useful to start a new AutoZero action because no new source is selected and an undesired mute would appear at the outputs. For such applications the TDA7461 could be switched in the "Auto Zero Remain" mode (Bit 6 of the subaddress byte). If this bit is set to high, the DATABYTE 0 could be loaded without invoking the AutoZero and the old adjustment value remains.

Figure 2. Input stages

Mixing Stage

This stage offers the possibility to mix the internal beep or the phone signal to any other source. Due to the fact that the mixing stage is also located behind the In-Gain stage fine adjustments of the main source level can be done in this way.

Loudness

There are four parameters programmable in the loudness stage (see fig. 3, 4, 5):

- Attenuation
- Center Frequency
- Loudness Q
- Flat Mode: in this mode the loudness stage works as a 0 - 15dB attenuator.

Softmute

The digitally controlled softmute stage allows muting/demuting the signal with a I²C bus programmable slope. The mute process can either be activated by the softmute pin or by the I²C bus. The slope is realized in a special S shaped curve to mute slow in the critical regions (see figure 6).

For timing purposes the Bit 3 of the I²C bus output register is set to 1 from the start of muting until the end of demuting.

Figure 3. Loudness Attenuation @ fc = 400Hz (second order)

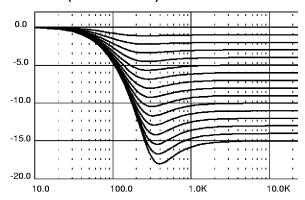

Figure 4. Loudness Center frequency @ Attn. = 15dB (second order)

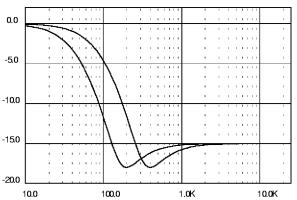

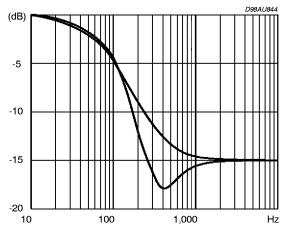

Figure 5. Loudness @ Attn. = 15dB, fc = 400Hz

Softstep Volume

When volume level is changed often an audible click appears at the output. The root cause of those clicks could be either a DC offset before the volume stage or the sudden change of the envelope of the audio signal. With the Softstep feature both kinds of clicks could be reduced to a minimum and are no more audible (see figure 7).

Bass

There are three parameters programmable in the bass stage (see figs 8, 9, 10, 11):

- Attenuation
- Center Frequency (60, 70, 80 and 100Hz)
- Quality Factors (1, 1.25, 1.5 and 2)

DC Mode

In this mode the DC gain is increased by 4.4dB. In addition the programmed center frequency and quality factor is decreased by 25% which can be used to reach alternative center frequencies or quality factors.

Treble

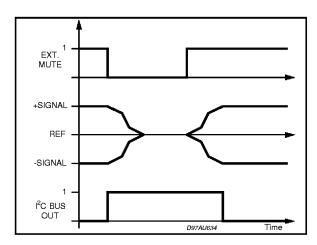

There are two parameters programmable in the treble stage (see figs 12, 13):

- Attenuation
- Center Frequency (10, 12.5, 15 and 17.5kHz).

Speaker Attenuator

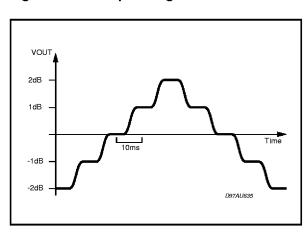

Due to practical aspects the steps in the speaker attenuators are not linear over the full range. At attenuations more than 24dB the steps increase from 1.5dB to 10dB (please see data byte specification).

Figure 6. Softmute Timing

Note: Please notice that a started Mute action is always terminated and could not be interrupted by a change of the mute signal.

Figure 7. Soft Step Timing

Note: For steps more than 1dB the softstep mode should be deactivated because it could generate a 1dB error during the blend-time

Figure 8. Bass Control @ fc = 80Hz, Q = 1

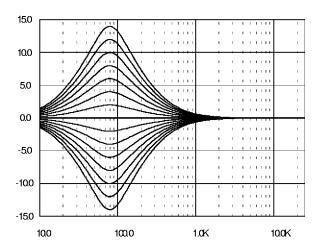

Figure 10. Bass Quality factors @ Gain = 14dB, fc = 80Hz

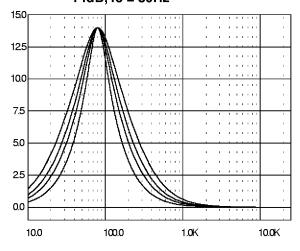

Figure 12. Treble Control @ fc = 17.5KHz

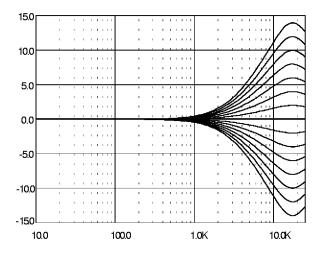

Figure 9. Bass Center @ Gain = 14dB, Q = 1

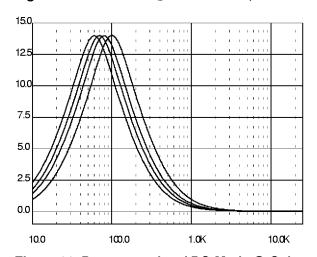

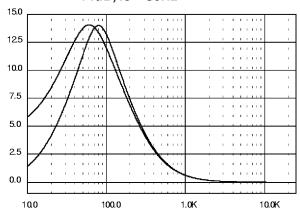

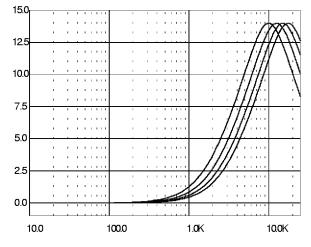

Figure 11. Bass normal and DC Mode @ Gain = 14dB, fc = 80Hz

Note: In general the center frequency, Q and DC-mode can be set independenty. The exception from this rule is the mode (5/xx1111xx) where the center frequency is set to 150Hz instead of 100Hz.

Figure 13. Treble Center Frequencies
@ Gain = 14dB

STEREODECODER PART

- No external components necessary
- PLL with adjustment free fully integrated VCO
- Automatic pilot dependent MONO/STEREO switching
- Very high suppression of intermodulation and interference
- Programmable Roll-Off compensation

- Dedicated RDS Softmute
- Highcut and Stereoblend characterisctics programmable in a wide range
- Internal Noiseblanker with threshold controls
- Multipath detector with programmable internal/external influence
- I²C bus control of all necessary functions

ELECTRICAL CHARACTERISTICS ($V_S = 9V$; deemphasis time constant = $50\mu s$, $V_{MPX} = 500 mV$, 75KHz deviation, f = 1KHz. $G_I = 6dB$, $T_{amb} = 25$ °C; unless otherwise specified).

Notes to the characteristics:

- $1.\ Intermodulation\ Suppression:\ measured\ with: 91\%\ pilot\ signal;\ fm=10kHz\ or\ 13kHz.$
- 2. Traffic Radio (V.F.) Suppression: measured with: 91% stereo signal; 9% pilot signal; fm=1kHz; 5% subcarrier (f = 57kHz, fm = 23Hz AM, m = 60%)
- 3. SCA (Subsidiary Communications Authorization) measured with: 81% mono signal; 9% pilot signal; fm = 1kHz; 10%SCA subcarrier (fs = 67kHz, unmodulated).
- 4. ACI (Adjacent Channel Interference) measured with: 90% mono signal; 9% pilot signal; fm =1kHz; 1% spurious signal (fs = 110kHz or 186kHz, unmodulated).

NOISE BLANKER PART

- internal 2nd order 140kHz high pass filter
- programmable trigger threshold
- additional circuits for trigger adjustment (devia-

tion, field-strenght)

- very low offset current during hold time
- four selectable pulse suppression times

Figure 17. Block diagram of the stereodecoder

DESCRIPTION OF STEREODECODER

The stereodecoder part of the TDA7461 (see Fig. 17) contains all functions necessary to demodulate the MPX signal like pilot tone dependent MONO/STEREO switching as well as "stereoblend" and "highcut" functions.

Adaptations like programmable input gain, roll-off compensation, selectable deemphasis time constant and a programmable fieldstrength input allow to use different IF devices.

Stereodecoder Mute

The TDA7461 has a fast and easy to control RDS mute function which is a combination of the audioprocessor softmute and the high-ohmic mute of the stereodecoder. If the stereodecoder is selected and a softmute command is sent (or activated through the SM pin) the stereodecoder will be set automatically to the high-ohmic mute condition after the audio signal has been softmuted.

Hence a checking of alternate frequencies could be performed. To release the system from the mute condition simply the unmute command must be sent: the stereodecoder is unmuted immediately and the audioprocessor is softly unmuted. Fig. 18 shows the output signal Vo as well as the internal stereodecoder mute signal. This influence of Softmute on the stereodecoder mute can be switched off by setting bit 3 of the Softmute byte to "0". A stereodecoder mute command (bit 0, stereodecoder byte set to "1") will set the stereodecoder in any case independently to the high-ohmic mute state.

If any other source than the stereodecoder is selected the decoder remains muted and the MPX pin is connected to Vref to avoid any discharge of the coupling capacitor through leakage currents.

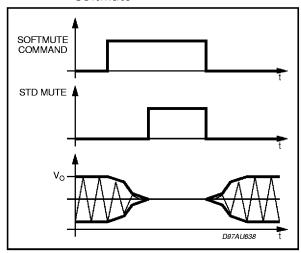

Input Stages

The Ingain stage allows to adjust the MPX signal to a magnitude of about 1Vrms internally which is the recommended value. The 4.th order input filter has a corner frequency of 80kHz and is used to attenuate spikes and noise and acts as an antialiasing filter for the following switch capacitor filters.

Demodulator

In the demodulator block the left and the right channel are separated from the MPX signal. In this stage also the 19 kHz pilot tone is cancelled. For reaching a high channel separation the TDA7461 offers an I2C bus programmable roll-off adjustment which is able to compensate the low-

Figure 18. Signals during stereodecoder's softmute

pass behaviour of the tuner section. If the tuner attenuation at 38kHz is in a range from 20.2% to 31% the TDA7461 needs no external network before the MPX pin. Within this range an adjustment to obtain at least 40dB channel separation is possible.

The bits for this adjustment are located together with the fieldstrength adjustment in one byte. This gives the possibility to perform an optimization step during the production of the carradio where the channel separation and the fieldstrength control are trimmed.

Deemphasis and Highcut.

The lowpass filter for the deemphasis allows to choose between a time constant of 50μs and 75μs (bit D7, Stereodecoder byte).

The highcut control range will be in both cases $t_{HC} = 2 \cdot t_{Deemp}$. Inside the highcut control range (between VHCH and VHCL) the LEVEL signal is converted into a 5 bit word which controls the lowpass time constant between $t_{Deemp}...3 \cdot t_{Deemp}$. There by the resolution will remain always 5 bits independently of the absolute voltage range between the VHCH and VHCL values.

The highcut function can be switched off by I2C bus (bit D7, Fieldstrength byte set to "0").

PLL and Pilot Tone Detector

The PLL has the task to lock on the 19kHz pilotone during a stereo transmission to allow a correct demodulation. The included detector enables the demodulation if the pilot tone reaches the selected pilottone threshold VPTHST. Two different thresholds are available. The detector output (signal STEREO, see block diagram) can be checked

by reading the status byte of the TDA7461 via I2C bus.

Fieldstrength Control

The fieldstrength input is used to control the high cut and the stereoblend function. In addition the signal can be also used to control the noise-blanker thresholds.

LEVEL Input and Gain

To suppress undesired high frequency modulation on the highcut and stereoblend function the LEVEL signal is lowpass filtered firstly. The filter is a combination of a 1st order RC lowpass at 53kHz (working as anti-aliasing filter) and a 1st-order switched capacitor lowpass at 2.2kHz. The second stage is a programmable gain stage to adapt the LEVEL signal internally to different IF.

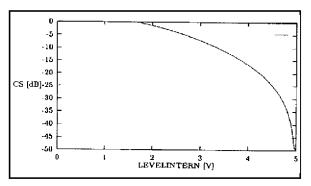

The gain is widely programmable in 16 steps from 0dB to 10dB (step = 0.67dB). These 4 bits are located together with the Roll-Off bits in the "Stereodecoder Adjustment" byte to simplify a possible adaptation during the production of the carradio.

Stereoblend Control

The stereoblend control block converts the internal LEVEL voltage (LEVEL INTERN) into an demodulator compatible analog signal which is used to control the channel separation between 0dB and the maximum separation. Internally this control range has a fixed upper limit which is the internal reference voltage REF5V. The lower limit can be programmed to be 33%, 42%, 50% or 58% of REF5V (see fig. 20).

To adjust the external LEVEL voltage to the internal range two values must be defined: the LEVEL

Figure 19. Internal stereoblend characteristics

gain L_G and VSBL. To adjust the voltage where the full channel separation is reached (VST) the LEVEL gain L_G has to be defined. The following equation can be used to estimate the gain:

$$L_{G} = \frac{REF5V}{Field\ strength\ voltage\ [STEREO]}$$

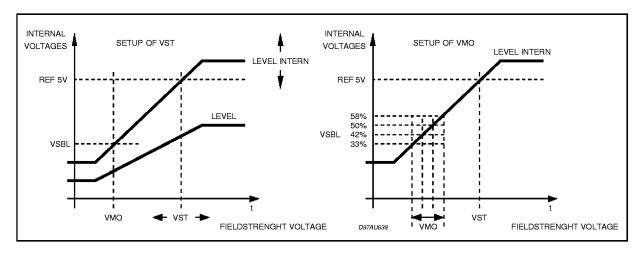

The gain can be programmed through 4 bits in the "Stereodecoder-Adjustment" byte.

The MONO voltage VMO (0dB channel separation) can be choosen selecting 33, 42, 50 or 58% of REF5V.

All necessary internal reference voltages like REF5V are derived from a bandgap circuit. Therefore they have a temperature coefficient near zero. This is useful if the fieldstrength signal is also temperature compensated.

But most IF devices apply a LEVEL voltage with a TC of 3300ppm. The TDA7461 offers this TC for the reference voltages, too. The TC is selectable with bit D7 of the "stereodecoder adjustment" byte.

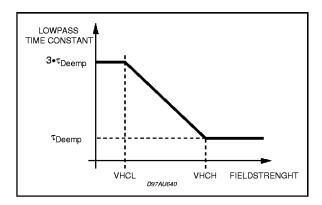

Figure 20. Relation between internal and external LEVEL voltage and setup of Stereoblend

Highcut Control

The highcut control setup is similar to the stereoblend control setup: the starting point VHCH can be set with 2 bits to be 42, 50, 58 or 66% of REF5V whereas the range can be set to be 17 or 33% of VHCH (see fig. 21).

Figure 21. Highcut characteristics

FUNCTIONAL DESCRIPTION OF THE NOISE-BLANKER

In the automotive environment the MPX signal is disturbed by spikes produced by the ignition and for example the wiper motor. The aim of the noiseblanker part is to cancel the audible influence of the spikes. Therefore the output of the stereodecoder is held at the actual voltage for $40\mu s$.

In a first stage the spikes must be detected but to avoid a wrong triggering on high frequency (white) noise a complex trigger control is implemented. Behind the triggerstage a pulse former generates the "blanking" pulse. To avoid any crosstalk to the signalpath the noiseblanker is

supplied by his own biasing circuit.

Trigger Path

The incoming MPX signal is highpass filtered, amplified and rectified. This second order highpass-filter has a corner frequency of 140kHz. The rectified signal, RECT, is lowpass filtered to generate a signal called PEAK. Also noise with a frequency 140kHz increases the PEAK voltage. The PEAK voltage is fed to a threshold generator, which adds to the PEAK voltage a DC dependent threshold VTH. Both signals, RECT and PEAK+VTH are fed to a comparator which triggers a re-triggerable monoflop. The monoflop's output activates the sample-and-hold circuits in the signalpath for 40µs.

The block diagram of the noiseblanker is given in fig.22.

Automatic Noise Controlled Threshold Adjustment (ATC)

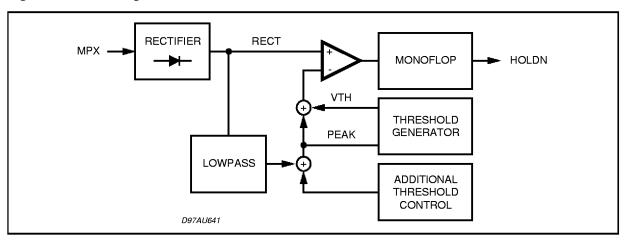

There are mainly two independent possibilities for programming the trigger threshold:

- a the low threshold in 8 steps (bits D0 to D2 of the noiseblanker byte)
- b the noise adjusted threshold in 4 steps (bits D3 and D4 of the noiseblanker byte, see fig. 14).

The low threshold is active in combination with a good MPX signal without any noise; the PEAK voltage is less than 1V. The sensitivity in this operation is high.

If the MPX signal is noisy the PEAK voltage increases due to the higher noise, which is also rectified. With increasing of the PEAK voltage the trigger threshold increases, too. This particular gain is programmable in 4 steps (see fig. 14).

Figure 22. Block diagram of the noiseblanker

Automatic Threshold Control

Besides the noise controlled threshold adjustment there is an additional possibility for influencing the trigger threshold. It is depending on the stereoblend control.

The point where the MPX signal starts to become noisy is fixed by the RF part. Therefore also the starting point of the normal noise-controlled trigger adjustment is fixed (fig. 16). In some cases the behaviour of the noiseblanker can be improved by increasing the threshold even in a region of higher fieldstrength. Sometimes a wrong triggering occures for the MPX signal often shows distortion in this range which can be avoided even if using a low threshold.

Because of the overlap of this range and the range of the stereo/mono transition it can be controlled by stereoblend. This threshold increase is programmable in 3 steps or switched off with bits D0 and D1 of the fieldstrength control byte.

Over Deviation Detector

If the system is tuned to stations with a high deviation the noiseblanker can trigger on the higher frequencies of the modulation. To avoid this wrong behaviour, which causes noise in the output signal, the noiseblanker offers a deviation dependent threshold adjustment.

By rectifying the MPX signal a further signal representing the actual deviation is obtained. It is

used to increase the PEAK voltage. Offset and gain of this circuit are programmable in 3 steps with the bits D6 and D7 of the stereodecoder byte (the first step turns off the detector, see fig. 15).

FUNCTIONAL DESCRIPTION OF THE MULTI-PATH DETECTOR

Using the internal detector the audible effects of a multipath condition can be minimized. A multipath condition is detected by rectifying the 19kHz spectrum in the fieldstrength signal.

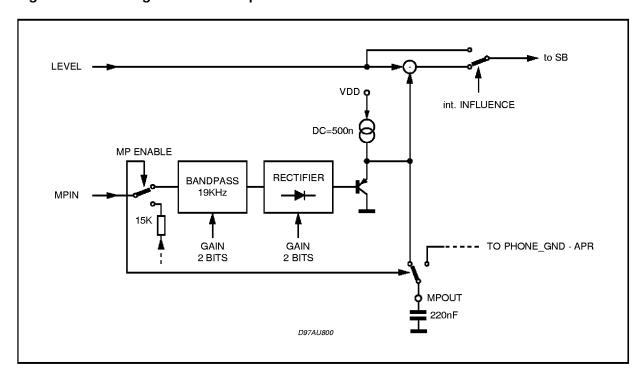

Selecting the "internal influence" in the configuration byte, the channel separation is automatically reduced during a multipath condition according to the voltage appearing at the MPOUT pin.

To obtain a optimal performance an adaptation is necessary. Therefore the gain of the 19kHz bandpass is programmable in four steps as well as the rectifier gain. The attack and decay times can be set by the external capacitor value.

TEST MODE

During the test mode which can be activated by setting bit D0 of the testing byte and bit D5 of the subaddress byte to "1" several internal signals are available at the CASSR pin. During this mode the input resistance of 100kOhm is disconnected from the pin. The internal signals available are shown in the software specification.

I²C BUS INTERFACE DESCRIPTION

Interface Protocol

The interface protocol comprises:

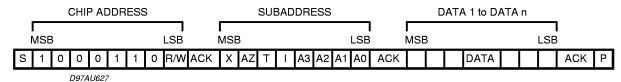

-a start condition (S)

/ write transmission) -a subaddress byte

-a sequence of data (N-bytes + acknowledge)

-a stop condition (P)

-a chip address byte (the LSB bit determines read

S = StartACK = Acknowledge

AZ = AutoZero-Remain

T = Testing

I = Autoincrement

P = Stop

MAX CLOCK SPEED 500kbits/s

The transmitted data is automatically updated after each ACK.

Transmission can be repeated without new chip address.

Auto increment

If bit I in the subaddress byte is set to "1", the autoincrement of the subaddress is enabled.
