

8-Port, 36V Constant-Current LED Driver with LED Fault Detection and Watchdog

MAX6980

General Description

The MAX6980 serial-interfaced LED driver provides eight open-drain, constant-current-sinking LED driver outputs rated at 36V. The device operates from a 3V to 5.5V supply. The MAX6980 supply and the LEDs' supply can power up in any order. The constant-current outputs are programmed together up to 55mA using a single external resistor. The MAX6980 operates with a 25Mbps, industry-standard, 4-wire serial interface.

The MAX6980 includes circuitry that automatically detects open-circuit LEDs. Fault status is loaded into the serial-interface shift register when LE goes high and is automatically shifted out on DOUT when the next data transmission is shifted in.

The MAX6980 includes a fail-safe feature for safety-related applications, which blanks the display if the serial interface fails. If the serial interface becomes inactive for more than 1s, all driver output latches are automatically cleared. This turns off all LEDs connected to the outputs. The shift register data is not disturbed. The outputs remain off until the driver output latches are updated with data turning them on, so recovery is automatic if the transmission failure is temporary. The watchdog function requires no software change to the application driving the MAX6980.

The MAX6980 uses the industry-standard shift-register-plus-latch-type serial interface. The driver accepts data shifted into an 8-bit shift register using data input DIN and clock input CLK. Input data appears at output DOUT eight clock cycles later to allow cascading of multiple MAX6980s. The latch-enable input, LE, loads the 8 bits of shift register data into an 8-bit output latch to set which LEDs are on and which are off. The output-enable input, $\overline{OE}$, gates all eight outputs on and off, and is fast enough to be used as a PWM input for LED intensity control.

The MAX6980 is one of a family of 10 shift-register-plus-latch-type LED drivers. The family includes 8-port and 16-port types, with 5.5V- or 36V-rated LED outputs, with and without open-circuit LED detection and watchdog. All versions operate from a 3V to 5.5V supply, and are specified over the -40°C to +125°C temperature range.

Applications

Variable Message Signs
Marquee Displays
Point-of-Order Signs
Traffic Signs
Gaming Features
Architectural Lighting

Features

- ◆ 25Mbps Industry-Standard 4-Wire Serial Interface at 5V
- ◆ 3V to 5.5V Logic Supply
- ◆ Eight Constant-Current LED Outputs Rated at 36V
- ◆ Up to 55mA Continuous Current per Output
- ◆ Output Current Programmed by Single Resistor
- ◆ 3% Current Matching Between Outputs
- ◆ 6% Current Matching Between ICs
- ◆ Watchdog Clears Display if Interface Fails
- ◆ Reports Open-Circuit LED Faults
- ◆ -40°C to +125°C Temperature Range

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE	PKG CODE
MAX6980AUE	-40°C to +125°C	16 TSSOP-EP*	U16E-3
MAX6980APE	-40°C to +125°C	16 PDIP	A16-2
MAX6980AAE	-40°C to +125°C	16 SSOP	P16-1

*EP = Exposed pad.

Typical Application Circuit and Selector Guide appear at end of data sheet.

Pin Configuration

8-Port, 36V Constant-Current LED Driver with LED Fault Detection and Watchdog

ABSOLUTE MAXIMUM RATINGS

(Voltage with respect to GND.)

V+	-0.3V to +6V
OUT ₋	-0.3V to +40V
DIN, CLK, LE, $\overline{OE}$, SET	-0.3V to (V+ + 0.3V)
DOUT Current	±10mA
OUT ₋ Sink Current	60mA
Total GND Current	480mA

Continuous Power Dissipation (T_A = +70°C)

16-Pin TSSOP-EP	(derate 21.3mW/°C above +70°C).....1702mW
16-Pin PDIP (derate 10.5mW/°C above +70°C).....842mW	
16-Pin SSOP (derate 7.1mW/°C above +70°C).....571mW	
Operating Temperature Range	-40°C to +125°C
Junction Temperature	+150°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10s)	+300°C

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(Typical Operating Circuit, V+ = 3V to 5.5V, T_A = T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at V+ = 5V, T_A = +25°C.) (Note 1)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS

Pin Description

PIN	NAME	FUNCTION
1	GND	Ground
2	DIN	Serial-Data Input. Data is loaded into the internal 8-bit shift register on CLK's rising edge.
3	CLK	Serial-Clock Input. Data is loaded into the internal 8-bit shift register on CLK's rising edge.
4	LE	Load-Enable Input. Data is loaded transparently from the internal shift register to the output latch while LE is high. Data is latched into the output latch on LE's falling edge and retained while LE is low.
5–12	OUT0–OUT7	LED Driver Outputs. OUT0 to OUT7 are open-drain, constant-current-sinking outputs rated to 36V.
13	$\overline{OE}$	Output-Enable Input. High forces outputs OUT0 to OUT7 high impedance without altering the contents of the output latches. Low enables outputs OUT0 to OUT7 to follow the state of the output latches.
14	DOUT	Serial-Data Output. Data is clocked out of the 8-bit internal shift-register to DOUT on CLK's rising edge.
15	SET	LED Current Setting. Connect SET to GND through a resistor (R_{SET}) to set the maximum LED current.
16	V+	Positive Supply Voltage. Bypass V+ to GND with a 0.1 μ F ceramic capacitor.
EP (TSSOP)	—	Exposed Pad. Although not required, connecting EP to ground improves thermal performance.

Detailed Description

The MAX6980 LED driver comprises a 4-wire serial interface driving eight constant-current-sinking, open-drain output ports. The outputs drive LEDs in either static or multiplex applications (Figure 1). The constant-current outputs are guaranteed for current accuracy, not only with chip-supply voltage variations (5V $\pm$ 10% and 3V to 5.5V), but also over a realistic range of driver output voltage drop (0.8V to 2.5V). The drivers use current-sensing feedback circuitry (not simple current mirrors) to ensure very small-current variations over the full allowed range of output voltage (see the *Typical Operating Characteristics*).

The 4-wire serial interface comprises an 8-bit shift register and an 8-bit transparent latch. The shift register is written through a clock input, CLK, and a data input, DIN, and the data propagates to a data output, DOUT. The data output allows multiple drivers to be cascaded and operated together. The contents of the 8-bit shift register are loaded into the transparent latch through a latch-enable input, LE. The latch is transparent to the shift register outputs when high, and latches the current state on the falling edge of LE.

Each driver output is an open-drain, constant-current sink, which should be connected to the cathode of either a single LED or a series string of multiple LEDs. The LED anode can be connected to a supply voltage of up to 36V, independent of the MAX6980 supply, V+. The constant-current capability is up to 55mA per output, set for all eight outputs by an external resistor, R_{SET} .

4-Wire Serial Interface

The serial interface on the MAX6980 is a 4-wire serial interface, using four inputs (DIN, CLK, LE, $\overline{OE}$) and a data output (DOUT). This interface is used to write display data to the MAX6980. The serial-interface data word length is 8 bits, D0–D7. See Figures 2 and 3.

The functions of the five interface pins are as follows. DIN is the serial-data input, and must be stable when it is sampled on the rising edge of CLK. Data is shifted in, MSB first. This means that data bit D7 is clocked in first, followed by 7 more data bits, finishing with the LSB D0.

CLK is the serial-clock input, which shifts data at DIN into the MAX6980's 8-bit shift register on its rising edge.

LE is the load input latch that transfers data from the MAX6980 8-bit shift register to its 8-bit latch when LE is high (transparent latch), and latches the data on the falling edge of LE (Figure 2).

The fourth input provides output-enable control of the output drivers. $\overline{OE}$ is high to force outputs OUT0 to OUT7 high impedance, without altering the contents of the output latches, and low to enable outputs OUT0 to OUT7 to follow the state of the output latches.

$\overline{OE}$ is independent of the serial-interface operation. Data can be shifted into the serial-interface shift register and latched regardless of the state of $\overline{OE}$.

DOUT is the serial-data output, which shifts data out from the MAX6980's 8-bit shift register on the rising edge of CLK. Data at DIN is propagated through the shift register and appears at DOUT eight clock cycles later. See Figure 2.

MAX6980

8-Port, 36V Constant-Current LED Driver with LED Fault Detection and Watchdog

Figure 3. LE and CLK to OUT_ Timing

Watchdog

The MAX6980 includes a watchdog circuit that monitors the CLK, DIN, and LE inputs. If there is no transition on any one of these inputs for nominally 1s, then the output latches are cleared and outputs OUT0–OUT7 go high impedance like the initial power-up condition. This turns off all LEDs connected to the outputs. The shift-register data does not change, just the output-latch data.

The watchdog is intended to be used as a fail-safe feature for applications that prefer a blank display to an incorrect display if the serial interface fails. When the watchdog triggers, the outputs remain off until the driver output latches are updated with data turning them on. Recovery is therefore automatic if the transmission failure is temporary, because the MAX6980 does not lock up in the watchdog timeout state. The MAX6980 operates correctly when the serial interface is next activated, and the watchdog circuit is reset and starts monitoring the serial interface again. The watchdog function requires no software change to the application driving the MAX6980.

LED Fault Detection

The MAX6980 includes circuitry that detects open-circuit LEDs automatically. An open-circuit fault occurs when an output is programmed to sink current but no current flows. Open circuits are checked just after the falling edge of $\overline{OE}$. If one or more output ports are detected with an open-circuit fault, the D6 and D5 bits of DOUT go high. If no open-circuit faults are detected, D6 and D5 are set to low. The data in the other 6-bit positions in DOUT are not altered.

Fault status is shifted out on DOUT when the next data transmission is shifted in after the rising edge of LE. LE is normally taken high after all 8 bits of new LED data have been clocked into the shift register(s), and then DOUT outputs data bit D7. On the next two rising edges of CLK, the 2 fault-status bits, D6 and D5, are clocked out in that order, followed by the remaining 5 unchanged data bits D4 to D0.

A typical fault-detecting application tests all the shifted out data. Bits D0–D4 and D7 are checked against the originally transmitted data to check data-link integrity. Bits D5 and D6 are checked first to see that they contain the same data (validating the status) and second, whether faults are reported or not by the actual logic level.

Figure 4 is the LE and CLK to DOUT timing diagram.

Applications Information

Selecting External Component R_{SET} to Set LED Output Current

The MAX6980 uses an external resistor R_{SET} to set the LED current for outputs OUT0 to OUT7. The minimum allowed value of R_{SET} is 327.3Ω, which sets the output currents up to 55mA. The reference value, 360Ω, sets the output currents to 50mA. To set a different output current, use the formula:

$$R_{SET} = 18,000 / I_{OUT}$$

where I_{OUT} is the desired output current in mA.

Figure 4. Fault Timing

8-Port, 36V Constant-Current LED Driver with LED Fault Detection and Watchdog

Computing Power Dissipation

The upper limit for power dissipation (P_D) for the MAX6980 is determined from the following equation:

$$P_D = (V_+ \times I_+) + (V_{OUT} \times DUTY \times I_{OUT} \times N)$$

where:

V_+ = supply voltage

I_+ = operating supply current when sinking I_{OUT} LED drive current into N outputs

DUTY = PWM duty cycle applied to $\overline{OE}$

N = number of MAX6980 outputs driving LEDs at the same time (maximum is eight)

V_{OUT} = MAX6980 port output voltage when driving load LED(s)

I_{OUT} = LED drive current programmed by R_{SET}

P_D = power dissipation, in mW if currents are in mA.

Dissipation example:

$I_{OUT} = 50\text{mA}$, $N = 8$, $DUTY = 1$, $V_{OUT} = 2\text{V}$, $V_+ = 5.25\text{V}$

$$P_D = (5.25\text{V} \times 25\text{mA}) + (2\text{V} \times 1 \times 50\text{mA} \times 8) = 0.931\text{W}.$$

Thus, for a 16-pin TSSOP package ($T_{JA} = 1 / 0.0213 = +46.95^\circ\text{C/W}$ from the *Absolute Maximum Ratings*), the maximum allowed ambient temperature T_A is given by:

$$T_{J(MAX)} = T_A + (P_D \times T_{JA}) = +150^\circ\text{C} = T_A + (0.931 \times 46.95^\circ\text{C/W})$$

so $T_A = +106.3^\circ\text{C}$.

Overtemperature Cutoff

The MAX6980 contains an internal temperature sensor that turns off all outputs when the die temperature exceeds approximately $+165^\circ\text{C}$. The outputs are re-enabled again when the die temperature drops below approximately $+140^\circ\text{C}$. Register contents are not affected, so when a driver is overdissipating, the external symptom is the load LEDs cycling between on and off as the driver repeatedly overheats and cools, alternately turning the LEDs off and then back on again.

Power-Supply Considerations

The MAX6980 operates with a chip supply V_+ , and one or more LED supplies. Bypass each supply to GND with a $0.1\mu\text{F}$ capacitor as close to the MAX6980 as possible. This is normally adequate for static LED driving. For multiplex or PWM applications, it is necessary to add an additional bulk electrolytic capacitor of $4.7\mu\text{F}$ or more to each supply for every four to 16 MAX6980s. The necessary capacitance depends on the LED load current, PWM switching frequency, and serial-interface speed. Inadequate V_+ decoupling can cause timing problems, and very noisy LED supplies can affect LED current regulation.
