

PI6C2309-1

3.3V Zero-Delay Buffer

Product Features

- Zero input-output propagation delay
- Less than 200ps input to output propagation delay
- Multiple low-skew outputs
 - Output-output skew less than 250ps
 - Device-device skew less than 700ps
 - Two banks of four outputs and one ON-chip
 - Internal feedback connection
- 10 MHz to 100 MHz operating range
- Low Jitter <200ps
- 3.3V operation
- High drive option (PI6C2309-1H)
- Temperature Rating: Commercial & Industrial
- Space-saving 16-pin, 150-mil SOIC package (W16) and 16-pin TSSOP package (L16)

Functional Description

Providing two banks of four outputs, the PI6C2309-1 is a 3.3V zero-delay buffer designed to distribute clock signals in applications including PC, workstation, datacom, telecom, and high-performance systems.

The PI6C2309-1 provides 9 copies of a clock signal that has less than 200ps propagation delay compared to the reference clock. The skew among the output clock signals for PI6C2309-1 is less than 250ps. When there are no rising edges on the REF input, the PI6C2309-1 enters a power-down state. In this mode, the PLL is off and all outputs are three-stated. This results in less than 50μA of current draw.

The PI6C2309-1 has two banks of four outputs and a CLK_OUT that can be controlled by the select inputs (see table below). If all output clocks are not required, Bank B can be three-stated. For test purposes or if the internal PLL is not needed, it can be bypassed.

Zero Delay and Skew Control

REF. Input to CLKA/CLKB Delay vs. Difference in Loading between CLK_OUT pin and CLKA/CLKB pins.

To achieve a Zero Delay between the input and output, all outputs should be uniformly loaded. The relative loading of CLK_OUT (with respect to the remaining outputs) can adjust the input-output delay. This is shown in the graph above.

For applications requiring zero input-output delay, all outputs, including CLK_OUT, should be equally loaded. Even if CLK_OUT is not used, it must have a capacitive load that is equal to that on every other output. If input-output delay adjustments are required, use the above graph to calculate loading differences between the feedback output and remaining outputs.

Maximum Ratings

Supply Voltage to Ground	-0.5V to +7.0V
DC Input Voltage (Except REF)	-0.5V to $V_{DD} + 0.5V$
DC Input Voltage REF	-0.5 to 7V
Storage Temperature	-65°C to +150°C
Maximum Soldering Temperature (10 seconds)	260°C
Junction Temperature	150°C
Static Discharge Voltage (per MIL-STD-883, Method 3015)	>2000V

Operating Conditions

Parameter	Description	Min.	Max.	Units
V_{DD}	Supply Voltage	3.0	3.6	V
T_A (2309-1, 2309-1H)	Commercial Temperature (Ambient)	0	70	°C
T_A (2309-1I, 2309-1HI)	Industrial Temperature (Ambient)	-40	85	
C_L	Load Capacitance	—	30	pF
C_{IN}	Input Capacitance	—	7	

Pin Description

Pin	Signal	Description
1	REF ⁽¹⁾	Input reference frequency, 5V tolerant input, allows spread spectrum clock input
2	CLKA1 ⁽²⁾	Clock output, Bank A
3	CLKA2 ⁽²⁾	Clock output, Bank A
4	V_{DD}	3.3V supply
5	GND	Ground
6	CLKB1 ⁽²⁾	Clock output, Bank B
7	CLKB2 ⁽²⁾	Clock output, Bank B
8	S2 ⁽³⁾	Select input, bit 2

16	CLK_OUT ⁽²⁾	Clock output, internal feedback on this pin

Notes:

1. Weak pull-down.
2. Weak pull-down on all outputs.
3. Weak pull-ups on these inputs.
4. REF and CLK_OUT inputs have a threshold voltage of $V_{DD}/2$.
5. Parameter is guaranteed by design and characterization. Not 100% tested in production.
