

68HC11/Bidirectional-Compatible μP Reset Circuit

MAX6314

General Description

The MAX6314 low-power CMOS microprocessor (μP) supervisory circuit is designed to monitor power supplies in μP and digital systems. The MAX6314's **RESET** output is bidirectional, allowing it to be directly connected to μPs with bidirectional reset inputs, such as the 68HC11. It provides excellent circuit reliability and low cost by eliminating external components and adjustments. The MAX6314 also provides a debounced manual reset input.

This device performs a single function: it asserts a reset signal whenever the V_{CC} supply voltage falls below a preset threshold or whenever manual reset is asserted. Reset remains asserted for an internally programmed interval (reset timeout period) after V_{CC} has risen above the reset threshold or manual reset is deasserted.

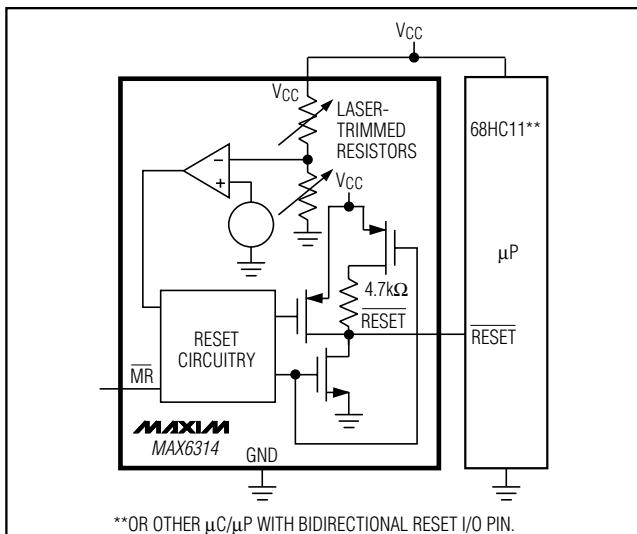

The MAX6314 comes with factory-trimmed reset threshold voltages in 100mV increments from 2.5V to 5V. Preset timeout periods of 1ms, 20ms, 140ms, and 1120ms (minimum) are also available. The device comes in a SOT143 package.

For a μP supervisor with an open-drain reset pin, see the MAX6315 data sheet.

Applications

Computers
Controllers
Intelligent Instruments
Critical μP and μC Power Monitoring
Portable/Battery-Powered Equipment

Typical Operating Circuit

Features

- ◆ Small SOT143 Package
- ◆ **RESET** Output Simplifies Interface to Bidirectional Reset I/Os
- ◆ Precision Factory-Set V_{CC} Reset Thresholds: 100mV Increments from 2.5V to 5V
- ◆ $\pm 1.8\%$ Reset Threshold Accuracy at $T_A = +25^\circ\text{C}$
- ◆ $\pm 2.5\%$ Reset Threshold Accuracy Over Temp.
- ◆ Four Reset Timeout Periods Available: 1ms, 20ms, 140ms, or 1120ms (minimum)
- ◆ Immune to Short V_{CC} Transients
- ◆ 5μA Supply Current
- ◆ Pin-Compatible with MAX811

| | | | C _{LOAD} = 250pF | | 666 | | |
| | | V _{CC} = 5V | C _{LOAD} = 200pF | | 333 | | |
| | | | C _{LOAD} = 400pF | | 666 | | |

Note 1: The MAX6314 monitors V_{CC} through an internal, factory-trimmed voltage divider that programs the nominal reset threshold.

Factory-trimmed reset thresholds are available in 100mV increments from 2.5V to 5V (see *Ordering and Marking Information*).

Note 2: This is the minimum time RESET must be held low by an external pull-down source to set the active pull-up flip-flop.

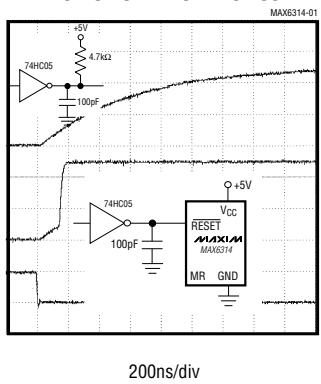

Note 3: Measured from RESET VOL to (0.8 x V_{CC}), R_{LOAD} = ∞.

68HC11/Bidirectional-Compatible μP Reset Circuit

Pin Description

| PIN | NAME | FUNCTION |
|-----|-----------------|--|
| 1 | GND | Ground |
| 2 | RESET | Active-Low Complementary Output. In addition to the normal n-channel pulldown, RESET has a p-channel pullup transistor in parallel with a $4.7\text{k}\Omega$ resistor to facilitate connection to μPs with bidirectional resets. See the <i>Reset Output</i> section. |
| 3 | MR | Manual Reset Input. A logic low on MR asserts reset. Reset remains asserted as long as MR is low, and for the reset timeout period (t_{RP}) after the reset conditions are terminated. Connect to V _{CC} if not used. |
| 4 | V _{CC} | Supply Voltage and Reset Threshold Monitor Input |

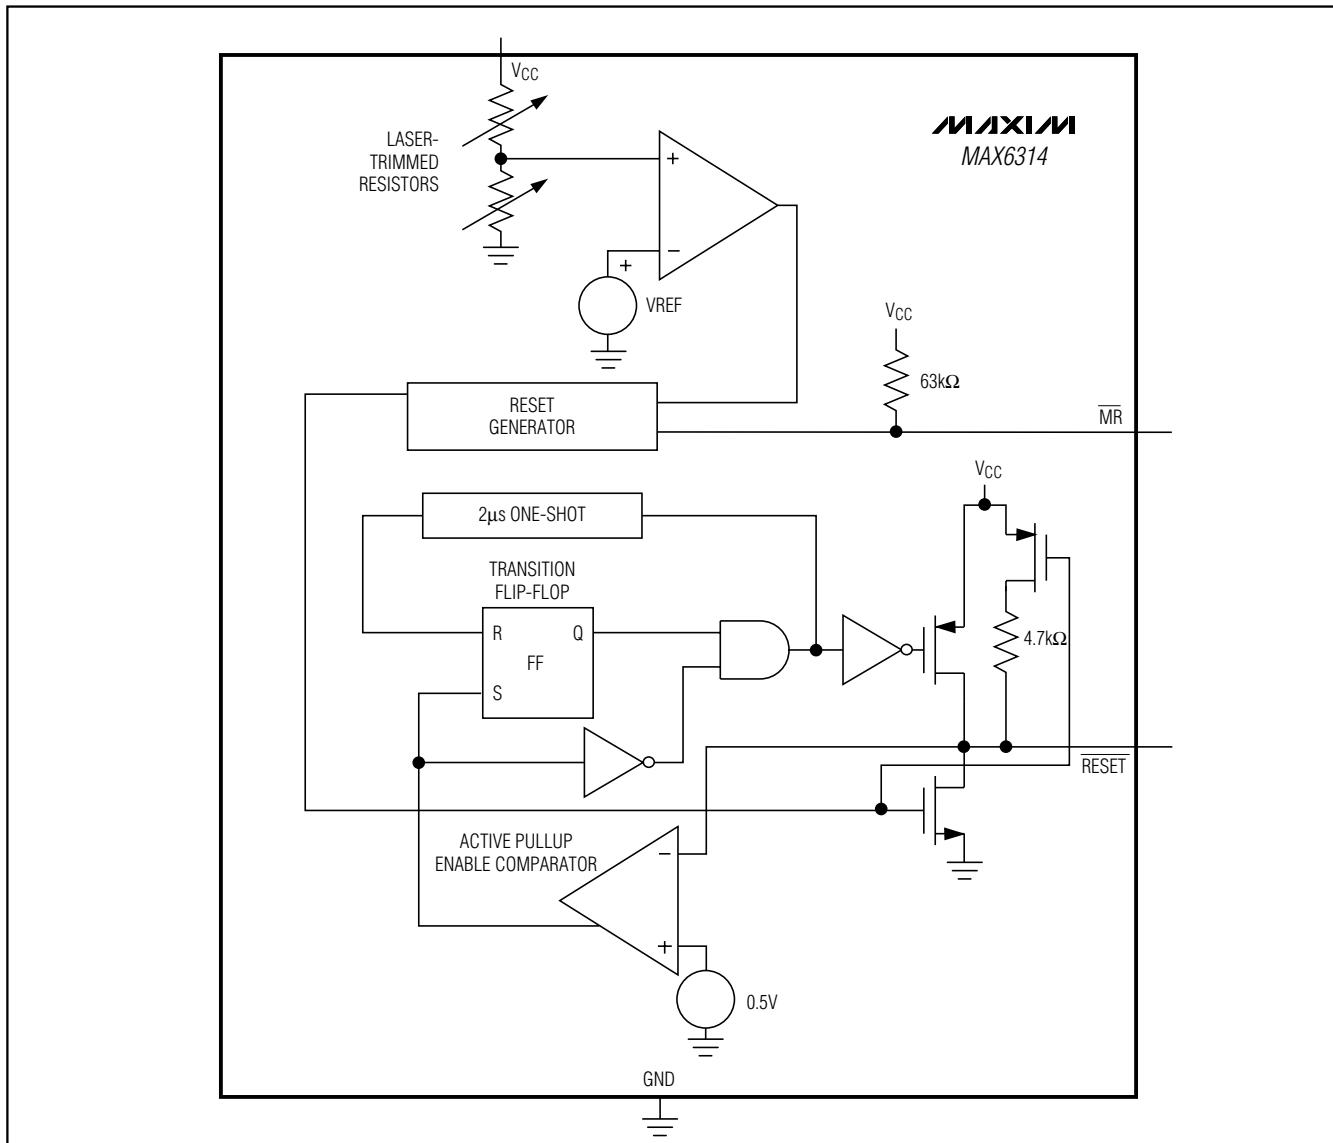

Figure 1. Functional Diagram

68HC11/Bidirectional-Compatible μP Reset Circuit

MAX6314

Detailed Description

The MAX6314 has a reset output consisting of a $4.7\text{k}\Omega$ pull-up resistor in parallel with a P-channel transistor and an N-channel pull down (Figure 1), allowing this IC to directly interface with microprocessors (μPs) that have bidirectional reset pins (see the *Reset Output* section).

Reset Output

A μP's reset input starts the μP in a known state. The MAX6314 asserts reset to prevent code-execution errors during power-up, power-down, or brownout conditions. RESET is guaranteed to be a logic low for $V_{CC} > 1\text{V}$ (see the *Electrical Characteristics* table). Once V_{CC} exceeds the reset threshold, the internal timer keeps reset asserted for the reset timeout period (t_{RP}); after this interval RESET goes high. If a brownout condition occurs (monitored voltage dips below its programmed reset threshold), RESET goes low. Any time V_{CC} dips below the reset threshold, the internal timer resets to zero and RESET goes low. The internal timer starts when V_{CC} returns above the reset threshold, and RESET remains low for the reset timeout period.

The MAX6314's RESET output is designed to interface with μPs that have bidirectional reset pins, such as the Motorola 68HC11. Like an open-drain output, the MAX6314 allows the μP or other devices to pull RESET low and assert a reset condition. However, unlike a standard open-drain output, it includes the commonly specified $4.7\text{k}\Omega$ pullup resistor with a P-channel active pullup in parallel.

This configuration allows the MAX6314 to solve a problem associated with μPs that have bidirectional reset pins in systems where several devices connect to RESET. These μPs can often determine if a reset was asserted by an external device (i.e., the supervisor IC) or by the μP itself (due to a watchdog fault, clock error, or other source), and then jump to a vector appropriate for the source of the reset. However, if the μP does assert reset, it does not retain the information, but must determine the cause after the reset has occurred.

The following procedure describes how this is done with the Motorola 68HC11. In all cases of reset, the μP pulls RESET low for about four E-clock cycles. It then releases RESET, waits for two E-clock cycles, then checks RESET's state. If RESET is still low, the μP concludes that the source of the reset was external and, when RESET eventually reaches the high state, jumps to the normal reset vector. In this case, stored state information is erased and processing begins from

scratch. If, on the other hand, RESET is high after the two E-clock cycle delay, the processor knows that it caused the reset itself and can jump to a different vector and use stored state information to determine what caused the reset.

The problem occurs with faster μPs; two E-clock cycles is only 500ns at 4MHz. When there are several devices on the reset line, the input capacitance and stray capacitance can prevent RESET from reaching the logic-high state ($0.8 \times V_{CC}$) in the allowed time if only a passive pullup resistor is used. In this case, all resets will be interpreted as external. The μP is guaranteed to sink only 1.6mA, so the rise time cannot be much reduced by decreasing the recommended $4.7\text{k}\Omega$ pullup resistance.

The MAX6314 solves this problem by including a pullup transistor in parallel with the recommended $4.7\text{k}\Omega$ resistor (Figure 1). The pullup resistor holds the output high until RESET is forced low by the μP reset I/O, or by the MAX6314 itself. Once RESET goes below 0.5V, a comparator sets the transition edge flip-flop, indicating that the next transition for RESET will be low to high. As soon as RESET is released, the $4.7\text{k}\Omega$ resistor pulls RESET up toward V_{CC} . When RESET rises above 0.5V, the active p-channel pullup turns on for the 2μs duration of the one-shot. The parallel combination of the $4.7\text{k}\Omega$ pullup and the p-channel transistor on-resistance quickly charges stray capacitance on the reset line, allowing RESET to transition low to high within the required two E-clock period, even with several devices on the reset line (Figure 2). Once the one-shot times out, the p-channel transistor turns off. This process occurs regardless of whether the reset was caused by V_{CC} dipping below the reset threshold, MR being asserted, or the μP or other device asserting RESET. Because the MAX6314 includes the standard $4.7\text{k}\Omega$ pullup resistor, no external pullup resistor is required. To minimize current consumption, the internal pullup resistor is disconnected whenever the MAX6314 asserts RESET.

Manual Reset Input

Many μP-based products require manual reset capability, allowing the operator, a test technician, or external logic circuitry to initiate a reset. A logic low on MR asserts reset. Reset remains asserted while MR is low, and for the reset active timeout period after MR returns high. To minimize current consumption, the internal $4.7\text{k}\Omega$ pullup resistor on RESET is disconnected whenever RESET is asserted.

68HC11/Bidirectional-Compatible µP Reset Circuit

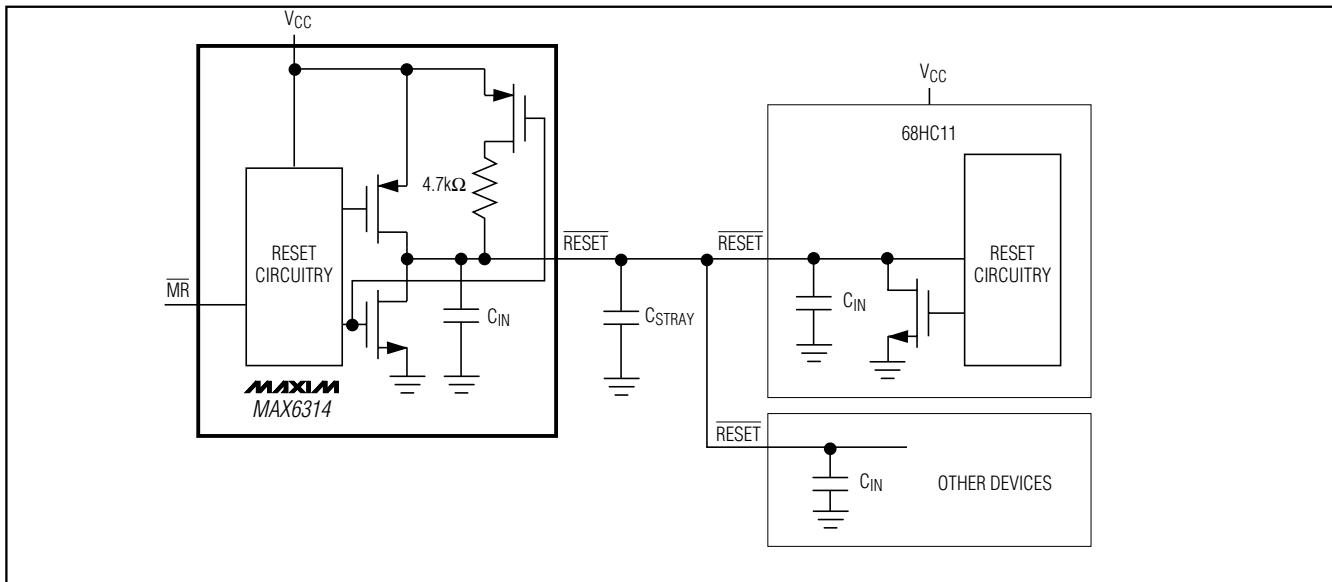

Figure 2. MAX6314 Supports Additional Devices on the Reset Bus

MR has an internal $63\text{k}\Omega$ pullup resistor, so it can be left open if not used. Connect a normally open momentary switch from **MR** to GND to create a manual reset function; external debounce circuitry is not required. If **MR** is driven from long cables or if the device is used in a noisy environment, connecting a $0.1\mu\text{F}$ capacitor from **MR** to ground provides additional noise immunity.

Applications Information

Negative-Going VCC Transients

In addition to issuing a reset to the µP during power-up, power-down, and brownout conditions, these devices are relatively immune to short-duration negative-going transients (glitches). The *Typical Operating Characteristics* show the Maximum Transient Duration vs. Reset Threshold Overdrive, for which reset pulses are not generated. The graph was produced using negative-going pulses, starting at VRST max and ending below the programmed reset threshold by the magnitude indicated (reset threshold overdrive). The graph shows the maximum pulse width that a negative-going Vcc transient may typically have without causing a reset pulse to be issued. As the amplitude of the transient increases (i.e., goes farther below the reset threshold), the maximum allowable pulse width decreases. A $0.1\mu\text{F}$ bypass capacitor mounted close to Vcc provides additional transient immunity.

Ensuring a Valid **RESET** Output Down to $V_{CC} = 0\text{V}$

When V_{CC} falls below 1V , **RESET** no longer sinks current—it becomes an open circuit. Therefore, high-impedance CMOS-logic inputs connected to **RESET** can drift to undetermined voltages. This presents no problem in most applications, since most µP and other circuitry is inoperative with V_{CC} below 1V . However, in applications where **RESET** must be valid down to $V_{CC} = 0\text{V}$, adding a pull-down resistor to **RESET** will cause any stray leakage currents to flow to ground, holding **RESET** low (Figure 3). $R1$'s value is not critical; $100\text{k}\Omega$ is large enough not to load **RESET** and small enough to pull **RESET** to ground.

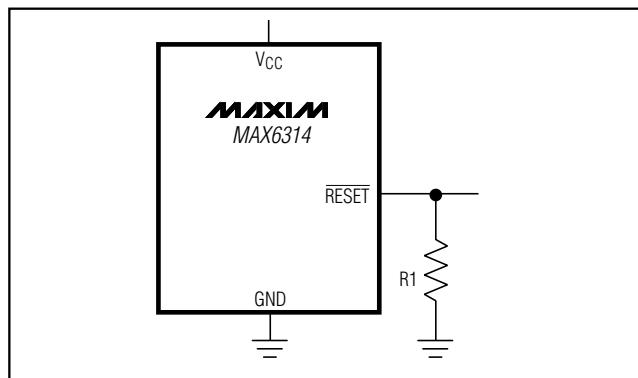

Figure 3. **RESET** Valid to $V_{CC} = \text{Ground}$ Circuit
