

# Industrial Ethernet PHY

**Dual PHY ASSP** 

uPD60620 uPD60620A uPD60621A

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Technology Corp. website (http://www.renesas.com).

#### **Notice**

- All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
- Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
- 3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
- 4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
- 5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
- 6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
- 7. Renesas Electronics products are classified according to the following three quality grades: "Standard", "High Quality", and "Specific". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as "Specific" without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as "Specific" or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics.

The quality grade of each Renesas Electronics product is "Standard" unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.

- "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.
- "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti- crime systems; safety equipment; and medical equipment not specifically designed for life support.
- "Specific": Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems;medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
- 8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
- 9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
- 10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
- 11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
- 12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.
- (Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority- owned subsidiaries.
- (Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

### **General Precautions in the Handling of ASSP Products**

The following usage notes are applicable to all ASSP products from Renesas. For detailed usage notes on the products covered by this manual, refer to the relevant sections of the manual. If the descriptions under General Precautions in the Handling of ASSP Products and in the body of the manual differ from each other, the description in the body of the manual takes precedence.

#### 1. Handling of Unused Pins

Handle unused pins in accord with the directions given under Handling of Unused Pins in the manual.

The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

#### 2. Processing at Power-on

The state of the product is undefined at the moment when power is supplied.

The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.

In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.

In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

#### 3. Prohibition of Access to Reserved Addresses

Access to reserved addresses is prohibited.

The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

#### 4. Clock Signals

After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

#### 5. Differences between Products

Before changing from one product to another, i.e. to one with a different part number, confirm that the change will not lead to problems.

The characteristics of ASSP in the same group but having different part numbers may differ because of the differences in internal memory capacity and layout pattern. When changing to products of different part numbers, implement a system-evaluation test for each of the products.

#### 6. Patent for IEEE1588

A number of patents exist for systems related to IEEE1588. Renesas would request that customers ensure they comply with the relevant rights for these patents. Renesas does not accept any responsibility for infringement of any patent rights by the customer.

#### How to Use This Manual

#### (1) Purpose and Target Readers

This manual is designed to provide the user with an understanding of the hardware functions and electrical characteristics of the PHY. It is intended for users designing application systems incorporating the PHY. A basic knowledge of electric circuits, logical circuits, and PHYs is necessary in order to use this manual. The manual comprises an overview of the product; descriptions of the PHY, system control functions, peripheral functions, and electrical characteristics; and usage notes.

Particular attention should be paid to the precautionary notes when using the manual. These notes occur within the body of the text, at the end of each section, and in the Usage Notes section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

The following documents apply to the Ethernet PHY products . Make sure to refer to the latest versions of these documents. The newest versions of the documents listed may be obtained from the Renesas Electronics Web site.

| Document<br>Type                 | Description   | Document Title   | Document No.                          |
|----------------------------------|---|--|---------------------------------------|
| User's<br>manual for<br>Hardware | Hardware specifications (pin assignments, memory maps, peripheral function specifications, electrical characteristics, timing charts) and operation description.  Note: Refer to the application notes for details on using peripheral functions. | User's manual<br>Industrial<br>Ethernet<br>PHY<br>Dual PHY ASSP                          | This User's manual<br>R19UH0083ED0100 |
| Application<br>Note              | Information on using peripheral functions and application examples. Sample programs. Information on writing programs in assembly language and C.  | Application Note industrial Ethernet Dual PHY ASSP Layout recommendation and design rule | R19AN0015ED0100                       |
| Renesas<br>Technical<br>Update   | Product specifications, updates on documents, etc.  | Customer Notification Ethernet PHY Operating Precautions                                 | R19TU0004ED0100                       |

# (2) Notation of Numbers and Symbols

| Abbreviation   | iation Full Form   |  |  |
|----------------|--|--|--|
| Register p.n   | Register n at PHY address p  |  |  |
| Register p.n.b | Bit 'b' in register address n at PHY address p   |  |  |
| Register PHY.n | PHY stands for PHY address "0" or "1" so this would mean register n in any of the two PHYs, can by PHY address 0 or PHY address 1. |  |  |

### (3) Register Notation

| Abbreviation | Full Form  |  |  |
|--------------|--|--|--|
| RW           | Readable or writeable  |  |  |
| SC           | Self Clearing  |  |  |
| RO           | Read Only  |  |  |
| WO           | Write Only   |  |  |
| LH           | Latch High, when the device sets the register it stays high until actively written to 0 even if the condition that set it disappears |  |  |
| LL           | Latch Low, the register stays low until actively written to 1  |  |  |
| WC           | Cleared by hardware after writing  |  |  |
| RC           | Cleared after reading by hardware  |  |  |
| NASR         | Not affected by software reset   |  |  |

### (4) List of Abbreviations and Acronyms

| Abbreviation | Full Form                                    |  |  |
|--------------|--|--|--|
| ACIA         | Asynchronous Communication Interface Adapter |  |  |
| bps          | bits per second                              |  |  |
| CRC          | Cyclic Redundancy Check                      |  |  |
| DMA          | Direct Memory Access                         |  |  |
| DMAC         | Direct Memory Access Controller              |  |  |
| GSM          | Global System for Mobile Communications      |  |  |
| Hi-Z         | High Impedance                               |  |  |
| IEBus        | Inter Equipment Bus                          |  |  |
| I/O          | Input/Output                                 |  |  |
| IrDA         | Infrared Data Association                    |  |  |
| LSB          | Least Significant Bit                        |  |  |
| MSB          | Most Significant Bit                         |  |  |
| NC           | Non-Connect                                  |  |  |
| PLL          | Phase Locked Loop                            |  |  |
| PU           | Pull Up                                      |  |  |
| PD           | Pull Down                                    |  |  |
| PWM          | Pulse Width Modulation                       |  |  |
| SFR          | Special Function Register                    |  |  |
| SIM          | Subscriber Identity Module                   |  |  |

### **General Description**

The extended dual-channel 10/100 Ethernet PHYs uPD60620 uPD60620A and uPD60621A are fully integrated Physical layer devices to connect to standard IEEE802.3 Ethernet networks. Today's industrial networking standards often implement daisy-chain or ring structures, in which a dual-channel PHY configuration makes a perfect fit.

These devices specifically focus on low latency and low jitter to support today's industrial Ethernet standards. In addition, the uPD60621A features hardware support for IEEE1588 V2. Renesas Electronics' specific enhanced diagnosis features allow permanent cable quality monitoring for easy maintenance in factory automation applications.

The PHY can connect to unshielded twisted-pair (UTP) cable via external magnetics or to optical fiber via fiber PMD modules. It interfaces to an Ethernet MAC layer through the IEEE 802.3 Standard Media Independent Interface (MII) or reduced MII (RMII) interface.

The uPD60621A also includes support for PTP according to IEEE1588 Version 1 and 2. To support this, an 80-bit clock is included in the PHY. Timestamps with a resolution of as low as 1ns can be taken from received and transmitted frames and events on external pins. The device also supports one-step and two-step timestamp insertion and supports transparent mode.

### 1.1 Overview of product features

- Two channel PHY
- Fully standard compliant with IEEE 802.3i/802.3u for 100BASE-TX, 100BASE-FX and 10BASE-T
- Integrated PMD sub-layer featuring adaptive equalization and baseline wander correction
- IEEE 802.3u auto-negotiation and parallel detection
- Full and half duplex operation
- Supports automatic polarity detection and correction
- Supports automatic MDI/MDI-X crossover
- Supports IEEE1588 V1 and V2 (uPD60621A only)
- Up to 20 programmable GPIO's for trigger and capture (uPD60621A only)
- 2.5V and 3.3V MAC interface
- Flexible MAC interface: MII and RMII (uPD60620 only)
- Serial management port (MDC/MDIO)
- Supports user programmable interrupts

- Enables software power-up/down and automatic power up/down by energy detection
- Single 3.3 V power supply with optional separated 1.5V
- Operating temperature: T<sub>ambient</sub> = -40 to +85°C (T<sub>iunction</sub> from -40 to +125°C)
- LQFP80 package (7 mm x 7 mm)

### 1.2 Special product features

- Low latency and low jitter for industrial networking
- Fast link-up option in auto-negotiation
- Fast link-loss detection
- Cable monitoring and error detection
- · Permanent cable quality tracking
- Enhanced system testability (such as bypass, loopback and cable length measurement by TDR)
- 1 ns resolution timer for hardware support of IEEE1588 (uPD60621A only)
- Timestamping function to timestamp incoming and outgoing frames and pin activity (uPD60621A only)
- Output pins controllable by internal clock (uPD60621A only)
- 100BASE-TX, 100BASE-FX Repeater (uPD60620A, uPD60621A only)
- 100BASE-TX to 100BASE-FX Media converter (uPD60620A, uPD60621A only)

### 1.3 Applications

- Industrial networking such as Profinet, Ethernet/IP, CIPsync, ModbusTCP, EtherCAT and SercosIII
- 10/100 Mbps LAN on motherboard (LOM) and network interface card (NIC)
- Switches, routers and repeaters with 10/100 Mbps capable ports
- Mobile base stations
- Test and measurement applications
- Home servers, broadband routers, printers, and IP phones
- Telecom base stations
- Real-time networking

### **Pin Functions**

#### 2.1 Pin-out Information

### 2.1.1 Pin Layout

### 2.1.2 Port Pins

| Power Supply              | Pins       | Comment  |  |

# **System Diagram**

The picture below shows the system diagram. The PHY is connected to the MAC through a MII or RMII interface. On the other side it is connected either to a CAT5 cable through magnetics or to a fibre cable.

### 3.1 Device block diagram

The device consists of two PHY's each connected to a PTP Framer block used to de-/encode the PTP frames and timestamp them, a PTP timer block containing the PTP clock, and an I/O block for general configuration and I/O handling. The PTP support is only available on the uPD60621A.

### **Global Hardware Description**

The device consists of two Ethernet PHYs combined in a single package. In addition it includes a control block which is used to control shared resources such as LED outputs, interrupts, and low-power modes. All are accessible through a two wire bidirectional Serial Management Interface.

### 4.1 Register Access

All registers can be accessed through the MII / SMI interface. The SMI is a serial interface defined in IEEE802.3 for access to PHY registers. The following picture shows a typical access using the SMI interface:

The PHY address denotes the address of the PHY, while the register address is the address of the register within the addressed PHY. The device uses the PHY addresses to support access to the PTP block and the Global Configuration registers. The address table is as follows:

| PHY Address (Binary) | Ressource            | Comments       |
|----------------------|----------------------|----------------|
| NM000                | PHY0                 |                |
| NM001                | PHY1                 |                |
| NM010                | reserved             |                |
| NM011                | Reserved             |                |
| NM100                | Reserved             |                |
| NM101                | Reserved             |                |
| NM110                | PTP                  | uPD60621A only |
| NM111                | GLOBAL_CONFIG<br>PTP |                |

The values of the bits N and M can be configured as a strap option.

# 4.2 General SMI Control Register 7.31

The following register is used for configuration of the SMI:

| Bit  | Name                           | Description   | Mode | Reset |
|------|--------------------------------|---|------|-------|
| 15   | RESET                          | Initiates a hardware reset of the complete device (stays active until cleared by software)              | W    | 0     |
|      |                                | 0: Release Reset  |      |       |
| 14   | SMI_SHORT<br>_PREAMBLE         | 1: Enable short preamble support.     0: Short Preamble mode for SMI interface not enabled              | RW   | 0     |
| 13:9 | Reserved                       | Write as 0  | RW   | 0     |
| 8    | Reserved                       | Write as 0  | RW   | 1     |
| 7:2  | Reserved                       | Write as 0  | RW   | 0     |
| 1    | PHY1_<br>DISREGARD<br>_ADDRESS | 1: PHY 1 ignores the PHY address when the device is being written 0: The PHY checks for the PHY address | RW   | 0     |
| 0    | PHY0_<br>DISREGARD<br>_ADDRESS | 1: PHY 0 ignores the PHY address when the device is being written 0: The PHY checks for the PHY address | RW   | 0     |

# 4.3 Power Control Register 7.30

The following register is used for configuration of the power options:

| Bit   | Name              | Description  | Mode | Reset |
|-------|-------------------|--|------|-------|
| 15:13 | POWER_ST          | 100: Device ready.   | RO   | 0     |
|       | ATUS              | Other than 100: Device not ready   |      |       |
| 12    | Reserved          |  | RW   | 0     |
| 11    | STOP              | 1: Device is disabled; only access to registers 7.25-7.31 in the GLOBAL_CONFIG area is possible. 0: Device is enabled  | RW   | 0     |
| 10    | PULSE_<br>PWD     | O: Pulse Output logic is enabled     Pulse Output logic for GPIO is powered down   | RW   | 1     |
| 9     | CAP_PWD           | Capture logic is enabled     Capture logic for GPIO is     powered down  | RW   | 1     |
| 8     | PTP_PWD           | 1: PTP is powered down 0: PTP is enabled   | RW   | 1     |
| 7     | Reserved          | Write as 1   | RW   | 1     |
| 6     | Reserved          | Write as 0   | RW   | 0     |
| 5     | C2C_STRAP<br>_DIS | Strap option for channel to channel loopback disable     Strap option for channel to channel loopback enable   | RW   | 0     |
| 4     | C2C_EN            | if "C2C_STRAP_DIS" = 1,  1: channel to channel loopback enable (repeater mode)  0: channel to channel loopback disable (normal mode)  if "C2C_STRAP_DIS" = 0,  don't care (Strap option effective) | RW   | 0     |
| 3:2   | Reserved          |  | RW   | 0     |
| 1     | PHY1PWD           | 1: The analog and digital part of the PHY1 is powered down. The PLL is powered down if all PHYs are powered down  0: PHY1 is enabled   | RW   | 0     |
| 0     | PHY0PWD           | 1: The analog and digital part of the PHY0 is powered down. The PLL is powered down if all PHYs are powered down  0: PHY0 is enabled   | RW   | 0     |

### 4.4 PHY Status Register 7.28

The following register shows the status of the PHYs.

| Bit   | Name            | Description  | Mode | Reset |
|-------|-----------------|--|------|-------|
| 15:10 | Reserved        | Write as 0   | RW   | 0     |
| 9     | PHY1_LINK       | 0: PHY 1 has no link                                       | RO   | 0     |
|       |                 | 1: PHY 1 has link  |      |       |
| 8     | PHY0_LINK       | 0: PHY 0 has no link                                       | RO   | 0     |
|       |                 | 1: PHY 0 has link  |      |       |
| 7:2   | Reserved        | Write as 0   | RW   | 0     |
| 1     | PHY1_<br>SYSRST | PHY is powered up and able to operate, Reset not active    | RO   | 0     |
|       |                 | 0: PHY is still powering up                                |      |       |
| 0     | PHY0_<br>SYSRST | 1: PHY is powered up and able to operate, Reset not active | RO   | 0     |
|       |                 | 0: PHY is still powering up                                |      |       |

The SYSRST registers are set by the PHY after the PLL has been powered up and has stabilized. They need to be 1 for the device to operate and to get access to all functions. Otherwise the internal 125 MHz clock is not available.

### 4.5 Strap option Register 7.27

The following register shows the strap option value latched after reset

| Bit | Name              | Description                                    | Mode | Reset        |
|-----|-------------------|--|------|--------------|
| 15  | QUICK_AUT<br>ONEG | Autonegotiation strap setting                  | RO   | Strap option |
| 14  | AUTO_NEG          | Quick Autonegotiation strap setting            | RO   | Strap option |
| 13  | AUTO_MDIX         | Auto MDIX strap setting                        | RO   | Strap option |
| 12  | FAST_JK           | Fast JK strap setting                          | RO   | Strap option |
| 11  | DUPLEX            | Duplex strap setting                           | RO   | Strap option |
| 10  | ADDR4             | PHY address bit 4 strap setting                | RO   | Strap option |
| 9   | ADDR3             | PHY address bit 3 strap setting                | RO   | Strap option |
| 8   | ETHERCAT          | MII timing strap setting                       | RO   | Strap option |
| 7   | MII               | MII/RMII strap setting                         | RO   | Strap option |
| 6:2 | Reserved          | Reserved                                       | RO   | 0            |
| 1   | PHY1 TX           | 100BASE-TX / 100BASE-FX strap setting for PHY1 | RO   | Strap option |
| 0   | PHY0 TX           | 100BASE-TX / 100BASE-FX strap setting for PHY0 | RO   | Strap option |

### 4.6 PHY LED Status Register 7.24

The following register shows the status of the PHYs after power up. To read the LED status for the PHYs first PHY\_SELECT must be written with the number of the required PHY and then the data for this PHY can be read from the register. The ACTIVE\_LED\_BLINK bit can be used to control the LED outputs of the device. If a GPIO is configured for link detection setting this register will cause the GPIO to blink while data transmission is ongoing.

| Bit | Name              | Name Description   |      | Reset |
|-----|-------------------|--|------|-------|
| 15  | Reserved          | Write as 0   | RO   | 0     |
| 14  | P0SD              | Signal Detect signal is active   | RO   | 0     |
| 13  | PHY_TXACT         | 1: PHY had TX activity since last reading  | R/LH | 0     |
|     |                   | 0: PHY had no TX activity since last reading                                     |      |       |
|     |                   | Cleared when read  |      |       |
| 12  | PHY_RXACT         | 1: PHY had RX activity since last reading  | R/LH | 0     |
|     |                   | 0: PHY had no RX activity since last reading                                     |      |       |
|     |                   | Cleared when read  |      |       |
| 11  | PHY_FD            | 1: PHY runs on full duplex   | RO   | 1     |
|     |                   | 0: PHY runs not on fill duplex   |      |       |

|     |                   | 0: PHY runs not on 10 MBit   |      |       |
| 7:4 | Reserved          |  | RO   | 0     |
| 3   | ACTIVE_LED _BLINK | 1: Link LED blinks if activity is detected and ON if link is up                  | RW   | 0     |
|     |                   | 0: Link LED does not blink on activity   |      |       |
|     |                   | When written this is set for the PHY number in PHY_SELECT                        |      |       |
| 2:0 | PHY_<br>SELECT    | Select number of the PHY for which the other bits of this register will be read. | RW   | 0     |
|     |                   | 000: Write to PHY0   |      |       |
|     |                   | 001: Write to PHY1   |      |       |
|     |                   | Others: Reserved   |      |       |

# 4.7 Interrupt Status register 7.20

To have a centralized register to get a summary of all possible interrupt sources an interrupt status register is placed at the top level in addition to the specific interrupt registers. The bits in this register are only set if the corresponding interrupt is enabled in the interrupt source modules.

| Bit | Name   | Description  | Mode | Reset |
|-----|--|--|------|-------|
| 15  | TIMESTAMP<br>_RX1_INT  | PHY1 has received a telegram which caused a timestamp to be taken (uPD60621A only)             | RC   | 0     |
| 14  | TIMESTAMP<br>_TX1_INT  | _INT which caused a timestamp to be taken (uPD60621A only)                                     |      | 0     |
| 13  | CAP_TS_ST<br>ORED  | S_ST The PTP capture unit stored an event (uPD60621A only)                                     |      | 0     |
| 12  | CAP_MEM_F<br>ULL_INT   | PTP capture buffer is full (uPD60621A only)  | R    | 0     |
| 11  | RESERVED   |  | R/LH | 0     |
| 10  | PTP_PERIO<br>D_INT   | Pulse generator started new period (uPD60621A only)  | RC   | 0     |
| 9   | TIMESTAMP PHY0 has received a telegram which caused a timestamp to be taken (uPD60621A only) |  | RC   | 0     |
| 8   | TIMESTAMP<br>_TX0_INT  | PHY0 has transmitted a telegram which caused a timestamp to be taken (uPD60621A only)          | RC   | 0     |
| 7   | PHY1_LINK_<br>DOWN_INT   |  |      | 0     |
| 6   | PHY1_BER_<br>OVER_INT  | PHY1 has triggered a BER Interrupt   | RC   | 0     |
| 5   | PHY1_FEQ_I<br>NT   | PHY1 has triggered a FEQ interrupt   | RC   | 0     |
| 4   | PHY1_GENE<br>RAL_INT   | PHY1_GENE PHY1 has triggered one of its  |      | 0     |
| 3   | PHY0_LINK_<br>DOWN_INT   | NK_ PHY0 has triggered a Link Down R0  |      | 0     |
| 2   | PHY0_BER_<br>OVER_INT  | PHY0 has triggered a BER Interrupt RC  |      | 0     |
| 1   | PHY0_FEQ_I<br>NT   | PHY0 has triggered a FEQ interrupt   | RC   | 0     |
| 0   | PHY0_GENE<br>RAL_INT   | PHY0 has triggered one of its internal interrupts except for Link Down, BER and FEQ interrupts | RC   | 0     |

### 4.8 Interrupt Mask register 7.21

To provide a summary of all possible interrupt sources an interrupt mask register is placed at the top level in addition to the specific interrupt registers. Note that this is just an additional option to mask all interrupts at a central register; all Interrupts need to be enabled at their respective location within the PHY or PTP register set. Therefore the mask register is by default enabled while the interrupt sources are by default disabled.

| Bit | Name          | Description              | Mode | Reset |
|-----|---------------|--------------------------|------|-------|
| 15  | TIMESTAMP_RX  | 0: Interrupt is enabled  | R/W  | 0     |
|     | 1_INT_MASK    | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |
| 14  | TIMESTAMP_TX  | 0: Interrupt is enabled  | R/W  | 0     |
|     | 1_INT_MASK    | 1: Interrupt is disabled |      |       |
|     |               | ( uPD60621A only)        |      |       |
| 13  | CAP TS STORE  | 0: Interrupt is enabled  | R/W  | 0     |
|     | D_MĀSK        | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |
| 12  | CAP MEM FUL   | 0: Interrupt is enabled  | R/W  | 0     |
|     | L_INT_MASK    | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |
| 11  | RESERVED      |                          | R/LH | 0     |
| 10  | PTP PERIOD IN | 0: Interrupt is enabled  | R/W  | 0     |
|     | T_MĀSK        | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |

|     | 0_INT_MASK    | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |
| 8   | TIMESTAMP_TX  | 0: Interrupt is enabled  | R/W  | 0     |
|     | 0_INT_MASK    | 1: Interrupt is disabled |      |       |
|     |               | (uPD60621A only)         |      |       |
| 7   | PHY1_LINK_DO  | 0: Interrupt is enabled  | R/W  | 0     |
|     | WN_INT_MASK   | 1: Interrupt is disabled |      |       |
| 6   | PHY1_BER_OVE  | 0: Interrupt is enabled  | R/W  | 0     |
|     | R_INT_MASK    | 1: Interrupt is disabled |      |       |
| 5   | PHY1_FEQ_INT  | 0: Interrupt is enabled  | R/W  | 0     |
|     | _MASK         | 1: Interrupt is disabled |      |       |
| 4   | PHY1_GENERA   | 0: Interrupt is enabled  | R/W  | 0     |
|     | L_INT_MASK    | 1: Interrupt is disabled |      |       |
| 3   | PHY0_LINK_DO  | 0: Interrupt is enabled  | R/W  | 0     |
|     | WN_INT_MASK   | 1: Interrupt is disabled |      |       |
| 2   | PHY0_BER_OVE  | 0: Interrupt is enabled  | R/W  | 0     |
|     | R_INT_MASK    | 1: Interrupt is disabled |      |       |
| 1   | PHY0_FEQ_INT  | 0: Interrupt is enabled  | R/W  | 0     |
|     | _MASK         | 1: Interrupt is disabled |      |       |
| 0   | PHY0_GENERA   | 0: Interrupt is enabled  | R/W  | 0     |
|     | L_INT_MASK    | 1: Interrupt is disabled |      |       |

#### **4.9 GPIO**

The GPIO pins can be configured depending on the application. Thus it is possible to repurpose unused pins for additional LEDs or PTP I/O. It is also possible to use the LED pins for PTP debug signals. The GPIO registers are located in the GLOBAL\_CONFIG address range.

Each GPIO pin has a 4-bit configuration register assigned. The register configuration is only used if the pin is not used for Ethernet handling. So, for example, if MII is used many pins are used for MII. If RMII is used the unused pins can be configured for other purposes.

Note that if a GPIO is configured for LED usage, the polarity is reversed so a LED is always enabled if pulled down.

### 4.9.1 GPIO\_CONFIG\_0 Register 7.0

| Bit   | Pin   | Description  | Mode | Reset       |
|-------|-------|--|------|-------------|
| 15:12 | GPIO3 | Same as GPIO0:   | RW   | 1100        |
|       |       |  |      | P1ACTIVELED |
| 11:8  | GPIO2 | Same as GPIO0 except:  | RW   | 1000        |
|       |       | 0101: GPIO is Output for PTP Packet transmitted on PHY 1, If PTP is disabled on this PHY the start of any telegram will activate the pin. (uPD60621A only) |      | P1LINKLED   |
|       |       | 0110: GPIO is Output for PTP packet received on PHY 1, If PTP is disabled on this PHY the start of any telegram will activate the pin. (uPD60621A only)    |      |             |
| 7:4   | GPIO1 | Same as GPIO0  | RW   | 1011        |
|       |       |  |      | P0ACTIVELED |
| 3:0   | GPIO0 | 0000: No change when written   | RW   | 0111        |
|       |       | 0001: GPIO is Output for PPS (Pulse per second) (uPD60621A only)   |      | P0LINKLED   |
|       |       | 0010: GPIO is Output for PTP-OUT1 (Output of Pulse Out unit 1) (uPD60621A only)  |      |             |
|       |       | 0011: GPIO is Output for PTP-OUT2<br>(Output of Pulse Out unit 2)<br>(uPD60621A only)  |      |             |
|       |       | 0100: GPIO is Output for PTP-OUT3 (Output of Pulse Out unit 3) (uPD60621A only)  |      |             |
|       |       | 0101: GPIO is Output for PTP Packet transmitted on PHY0, If PTP is disabled on this PHY the start of any telegram will activate the pin. (uPD60621A only)  |      |             |
|       |       | 0110: GPIO is Output for PTP packet received on PHY 0. If PTP is disabled on this PHY the start of any telegram will activate the pin.                     |      |             |

| (uPD60621A only)                                    |
|---|
| 0111: GPIO is Output for P0LINKLED                  |
| 1000: GPIO is Output for P1LINKLED                  |
| 1001: GPIO is Output for P0_100BT-<br>LED           |
| 1010: GPIO is Output for P1_100BT-<br>LED           |
| 1011: GPIO is Output for P0ACTIVELED                |
| 1100: GPIO is Output for P1ACTIVELED                |
| 1101: GPIO is Output for INT                        |
| 1110: GPIO is Output for CHIP_SYNC (uPD60621A only) |
| 1111: GPIO is Input                                 |

# 4.9.2 GPIO\_CONFIG\_1 Register 7.1

| Bit   | Name  | Description                                     | Mode | Reset            |
|-------|-------|---|------|------------------|
| 15:12 | GPIO7 | MII mode: always P0RXD3, regardless of setting. | RW   | 1110 in RMII     |
|       |       | RMII mode: same coding as GPIO0 except for:     |      |                  |

|       |        | 1110: SOF_TX1 Start of frame PHY1 TX path (uPD60621A only)                |      |              |

### 4.10 Strap Options

The device offers several configurations which can be selected as strap options. The related I/Os have integrated 40 k $\Omega$  pull-up or pull-down resistors which configure the device as described below. To change this configuration an external resistor of maximum 5 k $\Omega$  must be connected to the pin. An external resistor supporting the internal resistor is also advisable in case the device is used in a very noisy environment.

The following table shows the possible configuration options and the related pins. Unless otherwise noted all configuration options apply to both PHYs.

Table 4-1 Strap options

| Pin Name           | Function   | Default value |
|--------------------|--|---------------|
| P1RXD1             | 0: Autonegotiation disabled, 100BaseT<br>1: Autonegotiation enabled, 100BaseT  | 1, PU         |
| P1RXD0             | If Autonegotiation disabled:  0: Half Duplex  1: Full Duplex  If Autonegotiation enabled:  0: Parallel detect ends in half duplex mode  1: Forced Full Duplex in parallel detect | 1, PU         |
| P1RXCLK            | Disable Quick Autonegotiation     Quick Autonegotiation, shortest times     (Autonegotiation required)  See also special strap modes in table 4-2                                | 1, PU         |
| P0RXERR            | 0: Configure RMII Interface 1: Configure MII Interface   |               |
| P1RXERR            | O: Standard Mode, "JK" required for Start of Frame detection  1: Fast Mode, Only "J" required for Start of Frame detection   | 1, PU         |
| P0RXCLK            | 0: AUTOMDI-X disabled. 1: AUTOMDI-X enabled  | 1, PU         |
| PORXDV             | 0: FX Mode for PHY0, in this case the values of Autonegotiation, Duplex are ignored for this PHY.  1: TX Mode for PHY0   | 1, PU         |
| P1RXDV             | O: FX Mode for PHY1, in this case the values of Autonegotiation, Duplex ignored for this PHY.  1: TX Mode for PHY1   | 1, PU         |
| P0RXD0 /<br>P0RXD1 | Configures the upper two bits N and M of the PHY addresses  00: device uses address 00xxx for SMI  |               |

|         | 0: Synchronous mode for TXCLK. TXCLK is synchronous to XCLK0. This must be used for MACs that supply the MII TX data synchronously to the XCLK0 signal.                     |       |
|---------|---|-------|
| P1TXCLK | 1: Asynchronous mode for TXCLK. This mode reduces the TX Latency, but requires a MAC that handles the TXCLK signal to supply the MII TX data. This is the typical behavior. | 1, PU |

To configure the PHY via strap pins to special modes unusual combinations of the strap pins are used. The PHY modes are shown and described in table 4-2.

Table 4-2 Special strap options

| Mode         | Description                    | Strap combination         |
|--------------|--------------------------------|---------------------------|

# **PHY**

# 5.1 General Description

The device contains two PHYs. The block diagram for each is shown below:

#### 5.2 Clock Generator PLL

The PLL is a 125 MHz PLL which generates the clock for the 125 MHz part. It generates 32 output phases. The DSP selects which of these phases is used to sample the incoming signal. A single PLL is used for both PHYs. Therefore a Power Down of a PHY will only power down the PLL if both PHYs are powered down.

### 5.3 Analog Frontend

The analog frontend consists of two Programmable Gain Amplifiers, a low pass filter and the ADC.

#### 5.3.1 Adaptive Equalizing

The adaptive equalizer compensates for phase and amplitude distortion caused by the Physical channel consisting of magnetics, connectors, and CAT-5 cable. The equalizer can restore the signal for any good quality CAT-5 cable.

#### 5.3.2 100Base TX Receiver ADC

The Receiver ADC is part of the analog block. It is clocked with a 125 MHz clock which can be selected by the DSP from one of 32 phases.

### 5.4 Digital Signal Handling

The following chapters describe how the signal is handled in the digital part of the PHY.

#### 5.4.1 DSP

The DSP is re-shaping the received signal so it can be further processed. The ADC samples the signal at 125MHz. However the frequency of the signal is significantly lower than 125MHz due to the MLT-3 coding. Based on the received and decoded signal the DSP can measure the quality of the signal and either adjust internal filters or adjust the sampling phase of the ADC. One of the internal filters can be read to observe the cable quality.

#### 5.4.2 Baseline Wander Correction

If the DC content of the signal is such that the low-frequency components fall below the low-frequency pole of the isolation transformer, then the drop characteristics of the transformer will become significant and baseline wander (BLW) on the received signal will result. To prevent corruption of the received data, the DSP corrects for baseline wander.

#### 5.4.3 NRZI/MLT-3 Encoding / Decoding

MLT3 is a specific version of a NRZI coding using a tri-level code where a change in the logic level represents a code bit "1" and the logic output remaining at the same level represents a code bit "0". Basically it uses the NRZI coding as input but the '1' is flipped to '-1' every second time. The main advantage is that it reduces the effective frequency on the cable to 1/4 or 125/8 MHz. The decoder converts the MLT-3 data coming from the DSP to a NRZ data stream. The conversion of data to NRZI/ MLT-3 encoded data is shown in the following picture.

This code is used on the Ethernet data lines in 100TX mode.

#### 5.4.4 Scrambler / Descrambler

To reduce EMI the data sent is scrambled before it goes on the line and descrambled in the receiver. This reduces the emission at specific frequencies and spreads the emissions over a wider frequency band.

Scrambling the data helps eliminate large narrow-band peaks for repeated data patterns, and spreads the signal power more uniformly over the entire channel bandwidth. The seed for the scrambler is generated from the PHY address, ensuring that in multiple-PHY applications each PHY will have its own scrambler sequence.

The descrambler descrambles the decoded NRZ cipher-text bit from the MLT-3 decoder. The cipher-text bit stream is decoded by addition (modulo 2) of a key stream to produce a plain-text bit stream.

During reception of IDLE symbols, the descrambler synchronizes its descrambler key to the incoming stream. Once synchronization is achieved, the descrambler locks on this key and is able to descramble incoming data.

#### 5.4.5 5B/4B Encoding / Decoding

The data on the line is coded 4B/5B and decoded on the receive path. The main purpose is to remove repeated values, i. e. 0000 is replaced by 11110 to ensure there is a signal change after a certain period. In addition it allows detection of faulty transmissions and adds control data.

The following table shows the relationship between payload data and the 5B interpretation.

| PCS code-<br>group [4:0] | Name | MII (TXD/RXD)<br>[3:0] | Interpretation                          |
|--------------------------|------|------------------------|---|
| 11110                    | 0    | 0000                   | Data 0                                  |
| 01001                    | 1    | 0001                   | Data 1                                  |

### 5.5 Functional Description

#### 5.5.1 Collision detection

When transmissions from two stations overlap, the resulting contention is called a collision. Collisions occur only in half duplex mode, where a collision indicates that there is more than one station attempting to use the shared Physical medium.

#### 5.5.2 Carrier Sense detection

Carrier Sense (CRS) is asserted by the PHY when either transmit or receive medium is non-idle. For half-duplex mode, Carrier Sense is asserted during transmission or reception. For full-duplex mode, Carrier Sense is asserted during reception.

#### 5.5.3 Auto Crossover (MDI/MDI-X)

The PHY automatically detects and corrects for the MDI/MDI-X crossover in TX modes. Auto-Crossover is disabled in FX Mode. If this function is disabled, crossover may be corrected manually through the Serial Management Interface. The status of the crossover function can be read from a status register. The detection process is started whenever the PHY is turned on and Auto Crossover is activated. As soon as the partner PHY is transmitting it will immediately adjust the crossover as required.

#### 5.5.3.1 Auto-Crossover when using 100BT Fix Mode

In 100BT manual mode the transmitter continuously transmits idles on the TX line. As the incoming echo from the transmitter path needs to be blocked there is no chance to listen on that line. Therefore a special non-standard implementation called 100BT idle burst mode is employed. The idle burst mode has two states, a period of idle burst and a period of random silence to detect incoming signals on the TX line. The time for the next transmission will be picked randomly. The decision to do a switchover will be made based on the reception of two signals within a specific time period.

The PHY will transmit bursts of 1  $\mu$ s after a waiting time of 0 - 63  $\mu$ s. In parallel it checks both lines for a signal. If a valid signal is received on the RX line, it will continue normal operation. If a valid signal is received on the TX line it will wait for 500 $\mu$ s and then reverse the setting (exchange TX and RX). Again after a time of 0 - 63 $\mu$ s it will send a burst of 1 us and in parallel check if there is a signal on one of the lines. This will continue until a valid signal is detected on the RX line.

The PHY will only do a crossover if it detects signals on the actual TX line. On an open line it will not exchange the RX/TX lines as it cannot receive any signals.

The duration of this process can be  $<1~\mu s$  if the signal is initially recognized correctly and approximately 565 $\mu s$  if crossover is required.

### 5.5.3.2 Auto-Crossover when using Autonegotiation or 10BT Mode

Since the auto-negotiation's method of communication builds upon the link pulse mechanism employed by 10BASE-T MAUs to detect the status of the link, the energy detection upon FLPs bursts is the same as the NLPs. The NLP is a pulse transmitted every 16±8 ms. and its pulse width is 100ns. Typical burst width is 2 ms.

After reset the PHY will check for a signal on the incoming lines. As it is in its "Break\_link\_timer" state it will not start transmission before this timer is expired. If there is a signal detected in that period it will adjust the MDI/X accordingly and continue. If no signal is detected it will start transmitting the FL-Pulses to establish a connection. As the switchover is in general done during the duration of the Break\_link\_timer, there is no additional time required for Auto-Crossover in Autonegotiation Mode.

# 5.5.3.3 Auto-Crossover when connecting Autonegotiation and 100BT Mode

This is a situation in which one link partner A is in auto-negotiation mode and the other partner F is set to 100 Mb/s fix mode.

After power-up the forced PHY F will start sending FLP while the other link partner A is in Transmit disable state. So while PHY A will wait for its <code>break\_link\_timer</code> time (1200ms-1500ms) the forced PHY F will turn itself off randomly for every time period of <code>sample timer</code> (62±2us) to listen for a signal on its TX line. It will not change its transmit line pair unless it detects a contention. PHY A adjusts its Autocrossover state as it received a signal during its <code>break\_link\_timer</code> expiration time. When PHY A moves to <code>ABILITY\_DETECT</code> mode and transmits FLP PHY F detects these pulses. As PHY A has already adjusted its autocrossover mechanism correctly, there is no need for PHY F to do so.

### 5.5.4 Auto-Polarity

The PHY automatically detects and corrects for polarity reversal in wiring in 10BASE-T mode. The result of polarity detection is indicated by the flag "XPOL", bit 4 in register PHY.27. Polarity is checked at end of packets in 10BASE-T.

### 5.5.5 Auto-Negotiation

The objective of the auto-negotiation function is to provide the means to exchange information between two devices that share a link segment and to automatically configure both devices to take maximum advantage of their abilities. Auto-negotiation protocol is a purely Physical layer activity and proceeds independently of the MAC controller.

Prior to the start of any kind of negotiation the PHY is required by the IEEE 802.3 Chapter 28 to wait the Break\_Link\_Timer time which is defined to be between 1200 ms and 1500 ms. This time is defined to make sure both PHYs are reset and reach a defined status prior to starting the negotiation process.

For the auto-negotiation function, the two PHYs communicate by sending FLP (Fast link Pulse) bursts for exchanging information with its link partner. A FLP burst consists of 33 pulse positions. The 17 odd-numbered pulse positions

contain a link pulse and represent clock information. The 16 even-numbered pulse positions represent data information. The data transmitted by an FLP burst is known as a "Link Code Word". These are fully defined in clause 28 of the IEEE 802.3 specification.

After the Break Link Timer has expired, the link down status is achieved and, if auto-negotiation is enabled, the PHY starts to send FLP bursts while trying to receive signals on its receive path. If it detects signals according to 10BaseT, 100BaseTX or 100BaseT standard, it will wait for FLP bursts and check the received signals until the autoneg\_wait\_timer period (typically 500ms) has expired and then switch to fix mode according to the received signal.

The following picture shows the FLP burst.

These 33 pulses contain an acknowledge bit which is cleared at the start of the sequence. Each partner starts to send FLP bursts and tries to receive them from the other with the acknowledge bit cleared.

After one partner has successfully received three identical FLP bursts it continues sending FLP bursts with the acknowledge bit set. The other partner will wait until it has received this answer for three times. After that both partners will send 6-8 FLP bursts with the acknowledge bit set to ensure that they have understood each other successfully. After that both PHYs will resolve the information and decide on the optimum configuration.

Therefore it is required that at least 9 FLP bursts are sent to initiate a successful auto-negotiation. Thus a successful auto-negotiation will last at least 72 ms up to 216 ms depending on the burst length, if all transmissions are successful and the next page function is not used. In case a pulse is distorted the process will start over again.

To improve the linkup time for two Renesas PHYs the nominal 16ms frame rate is reduced to allowed 8 ms and shortening the frame transmission time. In this case two Renesas PHYs are able to negotiate within 72 ms without hurting the IEEE spec.

This PHY supports auto-negotiation and implements the "Base page", defined by IEEE 802.3. It also supports the optional "Next page" function to get the remote fault number code.

### 5.5.5.2 Disabling Auto-Negotiation

Auto-negotiation can be disabled by register setting or by setting the appropriate strap pins. When auto-negotiation is disabled, the speed and duplex modes are decided by setting management interface registers or Parallel Detection.

### 5.5.5.3 Priority Resolution

There are four possible operating modes. In the order of priority these are:

100M full duplex (highest priority)

100M half duplex

10M full duplex

10M half duplex

Since two devices (local device and remote device) may have multiple abilities in common, a prioritization scheme exists to ensure that the highest common denominator ability is chosen. Full duplex solutions are always higher in priority than their half duplex counterparts.

10BASE-T is the lowest common denominator and therefore has the lowest priority. If a link is formed via parallel detection, then bit 0 in Register PHY.6 is cleared to indicate that the link partner is not capable of auto-negotiation. The controller has access to this information via the management interface. If a fault occurs during parallel detection, bit 4 of register PHY.6 is set. Register PHY.5 is used to store the link partner ability information, which is coded in the received FLPs. If the link partner is not auto-negotiation capable, then register PHY.5 is updated after completion of parallel detection to reflect the speed capability of the link partner.

### 5.5.5.4 Next Page Function

Additional information beyond that required by base page exchange is also sent via "next pages". This PHY supports the optional "next page" function.

Next page exchange occurs after the base page has been exchanged. Next page exchange consists of using the normal auto-negotiation arbitration process to send next page messages. Two message encodings are defined: Message pages, which contain predefined 11 bit codes, and unformatted pages.

Next page transmission ends when both ends of a link segment set their next page bits to logic zero, indicating that neither has anything additional to transmit. It is possible for one device to have more pages to transmit than the other device. Once a device has completed transmission of its next page information, it shall transmit message pages with null message codes and the NP bit set to logic zero while its link partner continues to transmit valid next pages. Auto negotiation capable devices shall recognize reception of message pages with null message codes as the end of its link partner's next page information.

The default value of the next page support is disabled (bit 15 of register PHY.4). To enable next page support, bit 15 of Register PHY.4 should be set to "1". Autonegotiation should be restarted, and the message code should be written to bit [10:0] of register PHY.7.

#### 5.5.5.5 Re-negotiation

When auto-negotiation is enabled, it may be re-started by one of the following events:

- 1. Link status is down.
- 2. Setting Auto-Negotiation Restart bit to high.

Auto-negotiation is started (not re-started) when 1) Hardware reset, 2) Software reset or 3) setting Auto-Negotiation Enable from low to high.

#### 5.5.5.6 Parallel Detection

The parallel detection function allows detection of link partners that support 100BASE-TX and/or 10BASE-T, but do not support auto-negotiation or are set to fix mode. The PHY is able to determine the speed of the link based on either 100M MLT-3 symbols or 10M Link Pulses. If the PHY detects either mode, it automatically reverts to the corresponding operating mode.

In this case the link is always half duplex as defined in the IEEE spec. If a link is formed via parallel detection, then register PHY.6.0 is cleared to indicate that the link partner is not capable of auto-negotiation. The controller has access to this information via the management interface. If a fault occurs during parallel detection, register PHY.6.4 is set. register PHY.5 is used to store the link partner ability information, which is coded in the received FLPs. If the link partner is not auto-negotiation capable, then register PHY.5 is updated after completion of parallel detection to reflect the speed capability of the link partner.

Similar to the auto-negotiation process the PHY waits for the Break\_Link\_Timer duration before starting parallel detection. After reception of the first link signals, the parallel detection process waits for another 500 ms to check if FLP bursts are received.

### 5.5.5.7 Parallel Detection → Speculative Full Duplex

In modern Ethernet systems it is unlikely that a 100 MBit fix mode PHY is actually using half duplex. However if the IEEE 802.3 is fulfilled the PHY doing autonegotiation will revert to half duplex operation following the parallel detect operation. Thus the result of the parallel detect mode is one PHY running at 100 MBit full duplex and the other running at 100 MBit half duplex. Although communication is possible this will lead to many errors as the half duplex configured PHY will continuously detect collisions when the full duplex PHY is transmitting and receiving simultaneously.

To avoid this situation the PHY can be configured to go into full duplex instead of half duplex in parallel detection mode by means of a strap option.

#### 5.5.6 Bad Line recognition

The PHY features a number of functions to control and observe the line to be able to ensure a reliable connection.

### 5.5.6.1 BER-Monitor

The PHY can continuously measure the bit error rate (BER) on the line and trigger an interrupt or put the link down if a configurable threshold is reached.

Bit errors are detected by checking the received symbols against the list of allowed symbols. There are two basic conditions for this check:

- 1. IDLE situation: When the PHY is in idle mode it should only receive IDLE symbols or the start of frame delimiter which is a J symbol. All other symbols indicate that a bit error has happened and are counted as errors.
- 2. Data transmission: During data transmission there are 32 possible symbols of which only 19 are valid symbols. The rest indicate a bit error and will be counted as such. Note that the /H/ symbol is also counted as an error symbol.

A pre-condition of the BER mechanism operation is the lock of the descrambler; it will try to adjust itself while receiving IDLE patterns and is considered locked if a reasonable number of IDLE patterns have been received and descrambled. Unless the descrambler is locked, the BER monitor is not operable, and no data can be received.

Register PHY.23 – BER

| Bit      | Name           | Description  | Mode | Default |
|----------|----------------|--|------|---------|
| 23:15    | BER_LNK_OK     | Link quality indication – indicates state of link monitor.   | R    | 0       |
|          |                | '0' – Not in 'Good Link' state   |      |         |
|          |                | '1' – In 'Good Link' state   |      |         |
|          |                | Will go up as soon as the counter is below the trigger level after start up. Can be used to detect link up after start up. |      |         |
| 23:14    | BER_CNT_LNK_EN | 1: A trigger on the BER or on the FEQ monitor will cause a link down.  | RW   | 1       |
|          |                | 0: A trigger on the BER/FEQ will just cause the state machine to leave "Good Link" state.                                  |      |         |
| 23.13:11 | BER_CNT_TRIG   | Trigger level for BER Count to define link up/down   | RW   | 2       |
|          |                | Counter in 2^(n -1) errors   |      |         |
|          |                | 0: >0 errors will trigger  |      |         |
|          |                | 1: >1 triggers   |      |         |
|          |                | 2: >2 triggers   |      |         |
|          |                | 3: >4 triggers   |      |         |
|          |                | 4: >8 triggers   |      |         |
|          |                | 5: > 16 triggers   |      |         |
|          |                | 6: >32 triggers  |      |         |
|          |                | 7: > 64 errors triggers  |      |         |

| 23.10:7 | BER_WINDOW | Length of time for BER counter in 0.005 * 2^n ms 0: BER counter functions disabled 1: 0.01 ms 2: 0.02 ms 3: 0.04 ms    | RW | 1 (0.01<br>ms) |
|---------|------------|--|----|----------------|
|         |            | 14: 81.92 ms 15: unlimited run window. Writing a 0 resets the BER counter and restarts the time window.                |    |                |
| 23:6:0  | BER_COUNT  | Counter for bit errors, shows the amount of errors in the past time window. Is updated every 100 µs if BER_WINDOW = 15 | R  | 0x0            |

#### 5.5.6.2 FEQ-Monitor

In order to optimize the reception of the incoming data, the DSP continuously adapts its filters to the incoming signal. To be able to monitor the line quality, one of the DSP filter coefficients can be monitored and an interrupt or link down can be triggered if programmable limits are exceeded.

The FEQ2 coefficient changes as the DSP tries to re-adapt to match a changed line characteristic caused for example by a line break or increased resistance due to corrosion. This change is done within 1 to  $9\mu$ s when the line condition changes depending on line length and cable quality. So by using the FEQ monitor, line changes can be safely detected within  $9\mu$ s.

The FEQ2 value is latched at link up time. By programming the FEQ2\_DELTA field in register PHY.24 the allowed deviation of this value can be set. Whenever the FEQ2 is outside of this border due to changes in line condition an interrupt or link down is initiated. Note that after a link down the FEQ2 value is relatched so then a link is established based on the then actual FEQ2 value. In this case the application needs to take control and decide how to continue.

Register PHY.24: FEQ Monitor Control Register

| Bit     | Name      | Description  | Mode | Default   |
|---------|-----------|--|------|-----------|
| 24.15:0 | FEQ_DELTA | Minimum change of value (compared to the reference value latched when the monitor is enabled after link up) that will trigger the FEQ interrupt and link down.  If the FEQ value differs by more than FEQ_DELTA the link goes down if the BER_CNT_LNK_EN is 1 and the BER monitor is enabled, The interrupt is also triggered if enabled.  'FFFF' – will disable monitor and cause the reference value to be re-latched continuously.  'FFFE' – will not change the FEQ_DELTA value but will instead allow read out the current reference value from FEQ_VAL.  Writing any other value will disable this mode. | W    | OxFFFF    |
| 24.15:0 | FEQ_VAL   | If FEQ_DELTA == FFFE  Bit 17:2 of the reference value.  Else  Bits 17:2 of the current FEQ2 coefficient.   | R    | Undefined |

The following picture gives an example of the value of the FEQ coefficient for several line lengths (in meters.)

The following picture gives an example of the dependency of the FEQ coefficient on the resistance of the line. The 0 Ohm resistance is the value for a 1 meter line, for the other values a resistor has been added to the RX line.

The blue circles indicate the typical variation of the FEQ2 value.

44

### 5.5.7 Latency

The latency is the length of time it takes for data to pass through the PHY from the line interface to the MII and also from the MII to the line interface on the TX side. For industrial real-time applications a short latency is very important as it has a significant influence on the cycle times that can be achieved and the accuracy at which a system can be operated. Both the latency itself and the variation in latency (jitter) should be as small as possible.

Although the Renesas PHY has already a very short latency, the PHY has a special mode that will reduce the latency even further. This mode is called "J-only mode" and is available on all devices of the PHY family.

A new telegram is initiated by two symbols "J" and "K" as shown in the picture below:

Before data is sent it is transformed from a 4-bit notation at the MII to a 5 bit notation on the line to ensure that enough transitions are available for the clock regeneration. In addition the 5-bit coding allows for transmission of additional control symbols to indicate start of frame and end of frame. A start of frame is indicated by the symbol 11000 or "J" followed by a 10001 or "K".

Standard devices (conforming to the Ethernet standard) must detect the leading "J"- and "K"- symbol of a telegram as start-of-frame, before they can start to output data on the MII interface. Thus two symbols have to be received before output can be started on the MII interface. The Renesas PHY offers a special mode to only decode the leading J-symbol and start receiving the data immediately. The PHY will thus output data on the MII following the first "J" symbol without waiting for the reception of the "K" symbol.

This reduces the roundtrip delay by 40ns. This PHY family is thus able to support a roundtrip delay <200ns. In the unlikely case that the "J" detection was due to a bit error and the next "K" symbol is not received the RX\_ERR signal is asserted and reception resumes.

### 5.5.8 Special Isolation Mode

In many applications it is desirable to have a more flexible option to configure the PHY compared to strap options which need to be decided when the board is produced. Usually a PHY will read the configuration from the strap pins and try to connect immediately after power up. This does not leave time for a microcontroller to change the configuration before the communication and setup with the partner PHY has been started. In special isolation mode the PHY will not connect to its partner PHY but stay quiet on the line until enabled by software. This mode provides time for a microcontroller to configure the PHY which means configuration can be controlled by firmware instead of hardware.

### 5.5.9 Repeater / Media converter

This PHY supports channel to channel loopback mode and can be used as physical repeater. In this mode, the received frame at each port is directly forwarded to the other port. Channel to channel loopback mode is configured by strap option or register setting. (Refer to 4.10 Strap Options and 4.3 Power Control Register 7.30)

As an application of repeater function, this PHY works as media converter (100BASE-TX to 100BASE-FX) by setting each port as 100BASE-TX and 100BASE-FX respectively,

# 5.6 PHY Register List

The PHY registers can be accessed at PHY address 0 for PHY 0 or PHY address 1 for PHY 1. These registers control only the PHY they belong to. Some of these registers are duplicated on the PHY address 7 registers to ease software handling.

## 5.6.1 Register PHY.0 - Basic Control

| Bit | Name                        | Description  | Mode  | Default      |
|-----|-----------------------------|--|-------|--------------|
| 15  | RESET                       | 1 = software reset   | RW/SC | 0            |
|     |                             | 0 = normal operation   |       |              |
|     |                             | When setting this bit do not set other bits in this register |       |              |
| 14  | LOOPBACK                    | 1 = enable internal loopback mode                            | RW    | 0            |
|     |                             | 0 = disable internal loopback mode                           |       |              |
| 13  | SPEED_                      | 1 = 100 Mb/s   | RW    | 1            |
|     | SELECTION                   | 0 = 10 Mb/s  |       |              |
|     |                             | This bit is ignored if autonegotiation is enabled (0.12=1).  |       |              |
| 12  | AUTO-<br>NEGOTIATION_       | 1 = Enable auto-negotiation process                          | RW    | Strap option |
|     | ENABLE                      | 0 = Disable auto-negotiation process                         |       |              |
| 11  | POWERDOWN                   | 1 = General Power down                                       | RW    | 0            |
|     |                             | 0 = normal operation   |       |              |
| 10  | ISOLATE                     | 1 = Electrically isolate PHY from MII                        | RW    | 0            |
|     |                             | 0 = Normal operation   |       |              |
| 9   | RESTART_<br>AUTONEGOTIATION | 1 = restart auto-negotiation process                         | RW/SC | 0            |
|     |                             | 0 = normal operation   |       |              |
| 8   | DUPLEX_MODE                 | 1 = Full duplex  | RW    | Strap        |
|     |                             | 0 = Half Duplex  |       | option       |
|     |                             | This bit is ignored if autonegotiation is enabled (0.12=1).  |       |              |
| 7   | COLLISION_TEST              | 1 = enable COL signal test                                   | RW    | 0            |
|     |                             | 0 = disable COL signal test                                  |       |              |
| 6:0 | RESERVED                    | Write as 0, ignore on Read                                   | RO    | 0            |

Writing to Register PHY.0 in order to change modes from 10BT to 100BT and vice versa (Autonegotiation disabled), will take approximately 2us. Mode changes from HD to FD and vice versa is instantaneous.

# 5.6.2 Register PHY.1 - Basic Control

|       |                    | 44 : 04 00   |      |                |
|       |                    | 14: 81.92 ms   |      |                |
|       |                    | 15: unlimited run Writing a 0 resets the BER counter and restarts the time window.   |      |                |
| 6:0   | BER-COUNT          | Counter for bit errors, shows the amount of errors in the past time window or every 100 µs if BER_WINDOW = 15. Writing 00 resets the BER counter and restarts the time window. | RO   | 0x0            |

# 5.6.18 Register PHY.24 – FEQ monitor Register

| Bit  | Name      | Description  | Mode | Default |
|------|-----------|--|------|---------|
| 15:0 | FEQ_DELTA | Minimum change of value compared to the reference value latched when the monitor is enabled, which will trigger the FEQ interrupt and link down. If the FEQ value differs by more than that value, the link goes down, if the BER_CNT_LNK_EN is 1 and the BER Monitor is enabled, The interrupt is triggered if enabled.  'FFFF' – will disable monitor and cause the reference value to be relatched continuously 'FFFE' – will not change the FEQ_DELTA value but enable to read out the current reference value, when FEQ_VAL is read, instead of the current value.  Writing any other value will disable this mode. | W    | 0xFFFF  |
| 15:0 | FEQ_VAL   | If FEQ_DELTA == FFFE Bit 17:2 of the reference value. Else Bits 17:2 of the current FEQ2 coefficient.  | RO   |         |

# 5.6.19 Register PHY.25 – Diagnosis Control/Status Register

| Bit  | Name              | Description  | Mode                    | Default |
|------|-------------------|--|-------------------------|---------|
| 15   | Reserved          | Write with 0; ignore on read   | RW                      | 0       |
| 14   | DIAG_INIT         | When set to '1', create one cycle pulse - init TDR test  | RW<br>(self<br>cleared) | 0       |
| 13:8 | ADC_MAX_<br>VALUE | Shows the signed maximum/minimum value of the reflected wave. After the TDR process has been started the PHY will send out a trigger pulse and wait for the reflected wave for 255 clock cycles of 8 ns. After the time has elapsed the DIAG_DONE bit is set. The ADC MAX_VALUE will indicate the maximum of the received wave if positive or the minimum if negative. | R                       | 0       |
| 13:8 | ADC_Trigger       | Threshold for pulse detection.  – should be 0.5V / 00111 for cable length detection or 1.5V / 01111 for no cable detection.  MSB should always be 0.   | W                       | 0       |
| 7    | DIAG_DONE         | Indicates that the counter has been stopped either by counter overrun or by a ADC trigger. Cleared after reading   | RO                      | 0       |
| 6    | DIAG_POL          | O: Counter stopped by positive trigger level     1: Counter stopped by negative trigger level  | RO                      | 0       |
| 5    | DIAG_SEL_LINE     | 1: perform diagnosis on TX line 0: perform diagnosis on RX line  | RW                      | 0       |
| 4:0  | PW_DIAG           | Pulse width for Diagnosis  0: Diagnosis turned off  Other: Pulse width = value*8ns   | RW                      | 0       |

# 5.6.20 Register PHY.26 – Diagnosis Counter Register

| Bit  | Name       | Description  | Mode | Default |
|------|------------|--|------|---------|
| 15:8 | CNT_WINDOW | Minimum time after which the counter stops. Used to filter out any pulses or reflections generated from the local connector or similar sources.  One tick equals approximately 0.8m  | RW   | 0       |
| 7:0  | DIAGCNT    | Indicates the location of the received signal which exceeded the threshold; When DIAG_INIT is set to '1' - initiated by HW to '000000'. '1111111' – indicates no reflection. Any value different from zero indicates a valid measurement. When no cable is present, the value will be '000001' (assuming threshold is set to the correct value). | RO   | 0       |
|      |            | One counter tick equals approximately 0.8 m  |      |         |

# 5.6.21 Register PHY.27 - Special Control/Status Indications

| Bit   | Name       | Description  | Mode                   | Default |
|-------|------------|--|------------------------|---------|
| 15:13 | Reserved   | Write as "000". Ignore on read   | RW                     | 0       |
| 12    | SWRST_FAST | SW reset counter testing   | RW                     | 0       |
|       |            | 1 = accelerates SW reset counter from 256us to 10 us for production testing.   |                        |         |

# **External Components**

### 6.1 Clock

The devices can be operated on an external 25 MHz clock in MII mode or an external 50 MHz clock in RMII mode. In addition for MII mode it contains an internal oscillator which may generate the required 25 MHz clock using an external 25 MHz crystal connected to the pins XCLK0 and XCLK1.

## 6.2 Internal Switching Regulator

The device contains an internal switching regulator which generates the internal 1.6V for the PHY from the external 3.3V power supply. It can be disabled by tying REGOF to 3.3V and connecting the pins mentioned below directly to a 1.6V power supply. Otherwise the REGOFF pin must be connected to GND.

| Pin name    | Pin number | Description                      |
|-------------|------------|----------------------------------|
| VDD15       | 30, 52     | 1.5V Digital VDD                 |
| VDDAPLL     | 11         | Analog 1.5V power supply for PLL |
| P1VDDMEDIA, | 0.40       | Analog 4 5 V november of an DLIV |
| P0VDDMEDIA  | 3, 19      | Analog 1.5V power supply for PHY |

### 6.2.1 Power-Up Sequence

In case the internal voltage regulator is not used and the 1.5V supply is supplied form an external source a special power up sequence is not required. However both power supplies must be stable within 100ms.

# Support of IEEE1588 (uPD60621A only)

Renesas Electronics' Ethernet PHY implements the precision time protocol (PTP) according to IEEE1588 to support the requirements of higher precision and faster production.

The PHY supports IEEE1588 V1 and V2 including transparent clock mode and one-step or two-step mode. Furthermore the PHY can timestamp incoming messages with a resolution of 1ns.

The following clock modes are supported:

- Ordinary clock
- Boundary clock
- Transparent clock

The PHY can timestamp events on any of the GPIO pins. Based on the internal synchronized clock it may generate up to three output signals which may generate single pulses or repetitive pulses with programmable pulse length. It is also possible to output a Pulse-Per-Second (PPS) signal. Resolution for the event time-stamping unit and the pulse generation unit is 8ns. Reception of a PTP message, transmission of a PTP message, an event on the event unit and the pulse generator can generate an interrupt.

#### 7.1 IEEE1588

The basic purpose of IEEE1588 is to synchronize clocks in different nodes and have them run at the same phase and frequency. One clock in a node is selected as the master clock and all other clocks (called "slave clocks") in the system are synchronized to the master clock. Special PTP frames are exchanged between the nodes to distribute the time value of the master clock and measure the travel times. Based on the master clock time value and the travel times of the slave clocks can be adjusted and synchronized.

To measure the travel time, timestamps can be taken when frames leave the PHY or when they are received by the PHY. The more precise these timestamps, the more precise the calculations of the travel times are, and the better the synchronization of the clocks. For the transmit frames the data is always sent at the clock edge of the 125 MHz clock and therefore the time-stamping logic, which is running at the same clock as the transmit logic, has an optimal accuracy. However, receive frames can arrive at any time within the 125MHz/8ns clock period so the receive time-stamping logic has an error of up to 8ns depending on the actual arrival time of the data within the clock period.

To optimize the reception of the incoming data, the receive DSP continuously shifts the time at which the data is sampled. This is done by using one of the phases of the 125MHz clock from the PLL. Thus the selected phase of the PLL is a precise indicator for the exact sampling time at which the incoming data arrived at the PHY. As each of these phases represents a 1ns timeslot it can be used to define the exact arrival time within the 8ns clock period. This data is also stored together with the timestamp.

There are two ways in which timestamps can be transmitted between the nodes. One way is called "One Step". In this mode the timestamps for transmit frames are directly embedded in the telegram itself.. This approach reduces the software overhead at the expense of increased latency. The other method is called a "Two Step" approach. In this mode the timestamps are taken at the time of transmit, but sent afterward in a "follow up" telegram. This method provides lower latency but generates more traffic and requires more software overhead.

## 7.2 Register access to PTP

Many registers within the PTP block are 80 bits or 48 bits wide to control the whole width of the time representation. To read or write these registers they must be accessed 5 times (5 \* 16 bits = 80 bits) or 3 times for the 48 bit wide registers in a row. Unless otherwise noted accesses are done with the least significant word (bits 15:0) first. The values are latched internally after the last value has been written.

### 7.3 1588 Clock Control

The clock keeps the time which is to be synchronized between the different nodes and it can be directly set, accelerated, decelerated, or adjusted over a defined period.

The accessible clock is 80 bits wide with the upper 48 bits counting the seconds and the lower 32 bit counting the nanoseconds. Thus the ns clock overflow is not at 0xFFFFFFF but at 10^9 ns (0x3B9ACA00). Internally, the clock also maintains 30 extra bits of sub-nanosecond resolution to handle drift correction.

As the clock is running at 125 MHz, the clock value is increased by 8ns with every clock cycle. This value can be adjusted to speed up or slow down the clock. So, although the clock is still incremented based on the 125 MHz clock, it can be fine-tuned so that the value reflects real time.

To access the clock, read the register five times to retrieve 16 bits each time.

### 7.3.1 CLOCK\_STATUS Register 6.0

| Bit  | Name                 | Description   | Mode | Default |
|------|----------------------|---|------|---------|
| 14   | EN_OFFSET_<br>CORR   | Enable offset correction     Disable offset correction     Automatically cleared after the                              | RW   | 0       |
|      |                      | offset correction is finished.  |      |         |
| 13   | OFFSET_RUN           | offset correction in process     offset correction done   | R    | 0       |
| 12   | EN_DRIFT_C<br>ORR    | enable drift correction     disable drift correction  | R/W  | 0       |
| 11:9 | CLOCK_READ _POS      | Value of pointer pointing to the CLOCK_READ register. If 0 next read is from least significant word of clock latch.     | R    | 0       |
| 8:6  | CLOCK_WRIT<br>E_POS  | Value of pointer pointing to the CLOCK_WRITE register. If 0 next write goes toleast significant word of clock latch.    | R    | 0       |
| 5:3  | OFFSET_WRI<br>TE_POS | Value of pointer pointing to the CLOCK_OFFSET register. If 0 next write goes toleast significant word off offset latch. | R    | 0       |
| 2:0  | DRIFT_WRITE<br>_POS  | Value of pointer pointing to the CLOCK_DRIFT register. If 0 next write goes toleast significant word off offset latch.  | R    | 0       |

### 7.3.2 CLOCK\_READ Register 6.1

The CLOCK\_READ register is used to read the actual value of the clock. It must be accessed five consecutive times to read the complete data. Any read to another register will reset the internal pointer and the next read will then again read the highest word. All accesses are done with the most significant word first.

| Bit  | Name       | Description          | Mode | Default |
|------|------------|----------------------|------|---------|
| 79:0 | CLOCK READ | Clock read register. | R    | 0       |

### 7.3.3 CLOCK\_WRITE Register 6.2

This register can be used to set the clock to a value. It must be written five consecutive times. The data is latched into the clock when the 5<sup>th</sup> word is written. All accesses are done with the most significant word first.

| Bits | Name        | Description          | Mode | Default |
|------|-------------|----------------------|------|---------|
| 79:0 | CLOCK_WRITE | Clock write register | W    |         |

### 7.3.4 CLOCK\_OFFSET Register 6.3

This register is used to adjust the clock to a new value. To avoid sudden jumps the offset is not added all at once; instead the "OFFSET" is added/subtracted to the clock value after "OFFSET\_INTERVAL" for "OFFSET\_COR\_COUNT" times. Thus the clock is slowly adjusted to the new value value and jumps are avoided.

All values are latched internally when the offset correction is stopped either when it is finished or if it is manually disabled and reenabled with the EN\_OFFSET\_CORR register bit.

| Bit   | Name             | Description                                   | Mode | Default |
|-------|------------------|---|------|---------|
| 47    | OFFSET_SIGN      | Sign,   | W    | 0       |
|       |                  | 1: Subtract offset                            |      |         |
|       |                  | 0: Add offset                                 |      |         |
| 46:44 | OFFSET           | Increase value in ns                          | W    | 0       |
| 43    | Reserved         | Write as 0                                    | W    | 0       |
| 42:32 | OFFSET_INTERVAL  | Interval in steps                             | W    | 0       |
|       |                  | 0: No interval                                |      |         |
|       |                  | 1: No interval                                |      |         |
|       |                  | 2: add every 2 <sup>nd</sup> step             |      |         |
|       |                  | 3: add every 3 <sup>rd</sup> step             |      |         |
|       |                  |   |      |         |
| 29:0  | OFFSET_COR_COUNT | Count, how often the<br>"step" value is added | W    | 0       |

## 7.3.5 CLOCK\_DRIFT Register 6.4

This register contains a correction value, which can be used to continuously correct the clock value to compensate for oscillator drift. The value in the DELTA\_VAL register is summed up every clock cycle (125MHz), as soon as the sum has exceeded 0x3fffffff a value of 1 an additional ns is depending on the DELTA\_SIGN bit added/subtracted from the clock value. This register is latched internally when the EN\_DRIFT\_CORR register bit is set.

The value for the DELTA\_VAL register is calculated based on the following formula:

DELTA\_VAL = 
$$\frac{drift \cdot 10^3 \cdot 2^{30}}{125[MHz]/(1 \pm drift)}$$

where:

drift[s/s] is correction value for clock  $\pm$ : use + when DELTA SIGN = 1, <math>use - when DELTA SIGN = 0

| Bit  | Name       | Description  | Mode | Default |
|------|------------|--|------|---------|
| 31   | DELTA_SIGN | Sign of the delta value.   | RW   | 0       |
|      |            | 1: Clock is slowed down  |      |         |
|      |            | 0: Clock is speeded up   |      |         |
| 30   | Reserved   | Ignore on read, write as 0   | RW   | 0       |
| 29:0 | DELTA_VAL  | Delta in fractions of ns, by which the increment value is corrected. So bit 29 represents ½ ns, bit 28 1/4 <sup>th</sup> ns, bit 27 1/8 <sup>th</sup> ns, etc. | RW   | 0       |

# 7.4 Frame Handling Unit

The following picture shows the block diagram for the frame handling unit. The incoming telegram is time stamped as it arrives and the timestamp is then stored together with other related information in the timestamp SRAM. This data enables software to handle two-step PTP. When an event happens -- either due to transmission or reception of a PTP message -- an interrupt can be generated.

#### 7.4.1 One step mode

For one-step PTP the timestamp is stored in the outgoing timestamp latch and is then integrated into the timestamp field of the frame before it is sent. The CRC is also corrected accordingly. Note that for one-step mode the latency through the PHY is increased as the insertion of the time stamp in the frame requires some processing of the frame.

### 7.4.2 Two step mode

For two-step PTP the timestamp of the Synch telegram is stored in the outgoing timestamp latch and is not integrated into the timestamp field of the frame before it is sent. It then needs to be read by software and is transmitted to the receiver in a separate FollowUp telegram.

### 7.4.3 Transparent Clock Mode

Transparent Clock is used to improve the accuracy of the time synchronization in long networks by eliminating the uncertainty it takes for synch telegrams to pass through switches. Depending on the load of the switch the residence time of a synch telegram in the switch varies. By measuring the time a synch frame stays in the switch and writing this value into the frame the accuracy is greatly improved as the slave clock can use this value to adjust its calculation of the master clock value.

To support Transparent Clock mode in hardware the PHY modifies the respective telegrams. When a PTP synch telegram is received in transparent clock mode, the lower 2(sec)+32(ns) bits of the timestamp value taken at reception are converted to ns and subtracted from the correction field. When a PTP telegram is sent, the transmit timestamp lower 2(sec)+32 (ns) bits are converted to ns and added to the correction field. Thus the correction field is incremented by the difference between transmit and reception time and the correction field correctly updated even if a telegram is received on one PHY and transmitted on the other. This handling can be enabled separately for each PHY and for transmit and receive.

The Transparent Clock function can only be used in one step mode. In two step mode the Transparent Clock function is not required but can be handled by using one of the Ordinary Clock modes for time stamping and handling the protocol in software based on the FollowUp telegrams. However even if the system typically uses two step mode it is still possible to use the one step mode setting.

For End to End Transparent clock the time a synch telegram takes to pass through the node is measured and either stored in the correction field of the telegram or the correction field of the FollowUp telegram. The correction field at the slave then contains the time that the telegram spend in the different switches etc. which act as a transparent clock. The PTP stack can use this value to calculate the raw line delay and eliminate the jitter that comes from the varying residence times in the switchesPeer to Peer Transparent Clock

For peer-to-peer transparent clock each node measures the delay to all surrounding nodes using the PdelayReq and Pdelay\_Resp mechanism. Thus all line delays in a network are known. Each node through which a Synch message passes adds the own residence time plus the line delay of the incoming link to the correction field. When this synch telegram arrives at the slave node it contains the complete line delay plus the residence times in its correction field except for the very last link. The delay on the last link is known to the slave and

thus the complete line delay is known. Although this method is more complex than the End to end transparent clock it offers much faster reconfiguration in case of line breaks.

# 7.4.4 Timestamp Status Register 6.6

The Timestamp Status register shows the status for each buffer:

| Bit   | Name                                | Description                        | Mode | Default |
|-------|-------------------------------------|------------------------------------|------|---------|
| 15:12 | Reserved write as 0, ignore on read |                                    | RW   |         |
| 11    | BUF_EMPTY_TX_PHY1                   | Buffer empty for TX bufferPHY1     | RW   | 0       |
| 10    | BUF_EMPTY_RX_PHY1                   | Buffer empty for RX buffer PHY1    | RW   | 0       |
| 9     | BUF_EMPTY_TX_PHY0                   | Buffer empty for TX buffer PHY0    | RW   | 0       |
| 8     | BUF_EMPTY_RX_PHY0                   | Buffer empty for RX buffer PHY0    | RW   | 0       |
| 7:4   | Reserved write as 0, ignore on read |                                    | RW   |         |
| 3     | OVERFLOW_BUF_TX_PHY1                | Buffer overflow for TX buffer PHY1 | RW   | 0       |
| 2     | OVERFLOW_BUF_RX_PHY1                | Buffer overflow for RX buffer PHY1 | RW   | 0       |
| 1     | OVERFLOW_BUF_TX_PHY0                | Buffer overflow for TX buffer PHY0 | RW   | 0       |
| 0     | OVERFLOW_BUF_RX_PHY0                | Buffer overflow for RX buffer PHY0 | RW   | 0       |

### 7.4.5 Timestamp Config Register 6.7

The Timestamp Configuration register is used to configure the framer unit and is used to select which register of the timestamp memory is read.

| Bit  | Name                               | Description  | Mode | Default |
|------|------------------------------------|--|------|---------|
| 15:8 |                                    | Reserved, write as 0, ignore on read   | RW   | 0       |
| 7    | DISREGARD_O<br>LDEST_TIMES<br>TAMP | O: Do not overwrite timestamp if buffer overruns / newest timestamp is lost     Overwrite oldest timestamp if buffer overruns / oldest | RW   | 0       |
|      |                                    | timestamp is lost  |      |         |
| 6:4  | TIMESTAMP_<br>SELECT               | Address at which timestamp buffer is read for the following access to the TIMESTAMP_LINE_EVENT register.                               | RW   | 0       |
|      |                                    | 001: Next read will get TX timestamp on PHY0   |      |         |
|      |                                    | 000: Next read will get RX timestamp on PHY0   |      |         |
|      |                                    | 011: Next read will get TX timestamp on PHY1   |      |         |
|      |                                    | 010: Next read will get RX timestamp on PHY1   |      |         |
|      |                                    | Others: Undefined  |      |         |
| 3:2  |                                    | Reserved, ignore on read, write as 0   | RW   |         |
| 1    | TS_EN_PHY1                         | Enable timestamping for PHY1   | RW   | 0       |
| 0    | TS_EN_PHY0                         | Enable timestamping for PHY0   | RW   | 0       |

### 7.4.1 TIMESTAMP\_LINE\_EVENT Register 6.8

The TIMESTAMP\_LINE\_EVENT register gives access to the timestamp memory which stores the time stamps generated by the framer logic when a PTP frame was transmitted or received. It stores transmit or receive timestamps separately for TX and RX frames. The TIMESTAMP\_SELECT bits in the TIMESTAMP\_CONGIGURATION register define if the TX or the RX buffer is accessed. The timestamp memory can hold up to four timestamps for RX and four timestamps for TX, A read will always retrieve the oldest valid dataset.

A timestamp set is combined of the timestamp itself, the source port identity and the sequence ID stored in a 192 bit wide register. This is organized as shown below:

| Bit     | Name               | Description   | Mode | Default   |
|---------|--------------------|---|------|-----------|
| 191:176 | MESSAGE_ID         | Message Type of the received message  | RO   | Undefined |
|         |                    | 001: PTP Sync message   |      |           |
|         |                    | 010: PDelayReq message  |      |           |
|         |                    | 011: PDelayResp message   |      |           |
|         |                    | 100 : Delay Req. message  |      |           |
| 175:96  | TIMESTAMP          | Timestamp of the related event described in bits 95:0.  | RO   | Undefined |
|         |                    | Bits 175:128: seconds   |      |           |
|         |                    | Pits 127:96: ns   |      |           |
| 95:16   | SOURCEPORTIDENTITY | sourcePortIdentity extracted from the PTP telegram . If TS_ALL_FRAMES_nn is set and a NonPTPFrame is received this field is empty.  | RO   | Undefined |
| 15:0    | SEQUENCE_ID        | Rolling number assigned by sending port and extracted from telegram.  | RO   | Undefined |
|         |                    | If TS_ALL_FRAMES is set, and also normal non-PTP telegrams are timestamped there may be no SEQUENCE_ID in the telegram, thus the SEQUENCE_ID is generated internally starting with 0. |      |           |

To read a data set the timestamp memory register has to be accessed 12 times. The least significant word is read first. The TIMESTAMP\_SELECT register must be written prior to each individual access to the timestamp memory register.

## 7.4.2 PTP\_CONFIG\_n Register 6.9 / 6.13

The PTP Config register is used to configure the framer unit. There is one PTP config register for each PHY. The config register for PHY 0 is located at address 6.9, for PHY1 at 6.13.

| Name                    | Description   | Mode   | Default  |
|-------------------------|---|--|--|
|                         | Reserved, ignore on read, write as 0  | RW   |  |
| TS_ALL_<br>FRAMES_RX    | 1: Enable timestamping for all received frames. The IPV4 and IPV6 filter bits are still used.   | RW   | 0  |
|                         | received frames   |  |  |
| TS_ALL_<br>FRAMES_TX    | 1: Enable timestamping for all transmitted frames. The IPV4 and IPV6 filter bits are still used.  | RW   | 0  |
|                         | 0: Disable timestamping for all transmitted frames.   |  |  |
| L2                      | 1: Timestamp all Layer 2 frames   | RW   | 0  |
|                         | 0: Do not timestamp layer 2 frames  |  |  |
| IPV4                    | 1: Timestamp frames containing IPV4 frames  | RW   | 0  |
|                         | 0: Do not timestamp IPV4 frames   |  |  |
| IPV6                    | 1: Timestamp frames containing IPV6 frames  | RW   | 0  |
|                         | 0: Do not timestamp IPV6 frames   |  |  |
| ONE_STEP                | 1: Enable one step mode for<br>the PHY. In this mode the<br>taken transmit timestamp is<br>integrated in the frame on the<br>fly and the CRC corrected. | RW   | 0  |
|                         | 0: Selct two step mode, the transmit timestamp is not integrated in the outgoing frame.   |  |  |
| P2P_DELAY_<br>WRITE_POS | Current position of the PORT_DELAY_PHY_n register   | R  | 0  |
| MODE_TX                 | Set the PTP mode for TX   | RW   | 1  |
|                         | 00: BC_PTP_V1 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 10: TC_E2E_PTP_V2 (transparent clock end-to-end mode)                           |  |  |
|                         | TS_ALL_FRAMES_RX  TS_ALL_FRAMES_TX  L2  IPV4  IPV6  ONE_STEP  P2P_DELAY_WRITE_POS   | Reserved, ignore on read, write as 0  TS_ALL_ FRAMES_RX  1: Enable timestamping for all received frames. The IPV4 and IPV6 filter bits are still used. 0: Disable timestamping for all received frames  TS_ALL_ FRAMES_TX  1: Enable timestamping for all transmitted frames. The IPV4 and IPV6 filter bits are still used. 0: Disable timestamping for all transmitted frames. The IPV4 and IPV6 filter bits are still used. 0: Disable timestamping for all transmitted frames.  L2  1: Timestamp all Layer 2 frames 0: Do not timestamp layer 2 frames 0: Do not timestamp layer 2 frames 0: Do not timestamp IPV4 frames 0: Do not timestamp IPV4 frames 0: Do not timestamp IPV6 frames 0: Do not timestamp IPV6 frames 0: Do not timestamp iPV6 frames 0: Do set timestamp is not integrated in the frame on the fly and the CRC corrected. 0: Selct two step mode, the transmit timestamp is not integrated in the outgoing frame.  P2P_DELAY_ WRITE_POS  Current position of the PORT_DELAY_PHY_n register  MODE_TX  Set the PTP mode for TX 00: BC_PTP_V1 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 10: TC_E2E_PTP_V2 (transparent clock end-to-end | Reserved, ignore on read, write as 0  TS_ALL_ FRAMES_RX  1: Enable timestamping for all received frames. The IPV4 and IPV6 filter bits are still used.  0: Disable timestamping for all received frames.  TS_ALL_ FRAMES_TX  1: Enable timestamping for all transmitted frames. The IPV4 and IPV6 filter bits are still used.  0: Disable timestamping for all transmitted frames. The IPV4 and IPV6 filter bits are still used.  0: Disable timestamping for all transmitted frames.  L2  1: Timestamp all Layer 2 frames  0: Do not timestamp layer 2 frames  0: Do not timestamp IPV4 frames  0: Do not timestamp IPV4 frames  0: Do not timestamp IPV4 frames  0: Do not timestamp IPV6 frames  0: Do selt two step mode for the PHY. In this mode the taken transmit timestamp is integrated in the frame on the fly and the CRC corrected.  0: Selct two step mode, the transmit timestamp is not integrated in the outgoing frame.  P2P_DELAY_ WRITE_POS  Current position of the PORT_DELAY_PHY_n register  MODE_TX  Set the PTP mode for TX  00: BC_PTP_V1 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 10: TC_E2E_PTP_V2 (transparent clock end-to-end mode) |

RENESAS

|     |         | (transparent clock peer-to-<br>peer mode)   |    |   |
|-----|---------|---|----|---|
| 1:0 | MODE_RX | Set the PTP mode for RX  00: BC_PTP_V1 (boundary clock mode) 01: BC_PTP_V2 (boundary clock mode) 10: TC_E2E_PTP_V2 (transparent clock endto-end mode) 11: TC_P2P_PTP_V2 (transparent clock peer-to-peer mode) | RW | 0 |

The following table gives an overview on how the different telegram types are handled depending on the configuration. An empty field means that nothing is done.

#### TX Path:

|                           | OC/BC<br>V1 | OC/BC<br>V1               | OC/BC<br>V2               | OC/BC<br>V2            | TC E2E                     | TC P2P                     |

#### 7.4.3 PHY\_DELAY\_TX\_n Register 6.11 / 6.15

The PORT\_DELAY\_PORT\_n register is used to adjust the timestamp by the latency of the PHY's TX path. This is by default set to 0 but may be corrected to also compensate for delays caused be the transformer. There is one register for each PHY. PTP assumes that the line delay including the PHY latency in both directions is identical, this may not be the case if PHYs from different vendors are used in a network. In this case the PHY\_DELAY\_TX\_PORT and PHY\_DELAY\_RX\_PORT values should be set. This value should be set to 40.

| Bit  | Name                    | Description  | Mode | Default |
|------|-------------------------|--|------|---------|
| 15:0 | PHY_DELAY_<br>TX_PORT_n | Value in ns by which timestamps taken for the PHYn on the TX side are corrected. | RW   | 0       |

#### 7.4.4 PHY\_DELAY\_RX\_n Register 6.12 / 6.16

The PORT\_DELAY\_PORT\_n register is used to adjust the timestamp by the latency of the PHYs RX path. This is by default set to the actual value but may be corrected to also compensate for delays caused be the transformer. Typically this value should be 190 if Fast-JK mode is used, otherwise 230.

| Bit  | Name                    | Description  | Mode | Default |
|------|-------------------------|--|------|---------|
| 15:0 | PHY_DELAY_<br>RX_PORT_n | Value in ns by which timestamps taken for the PHYn on the RX side are corrected. | RW   | 0       |

#### 7.5 Input Capture Unit

The input capture unit can be used to timestamp events on any of the GPIO pins. The timestamps are stored in a special memory area which can be accessed through the SMI via dedicated registers. The memory is configured as a FIFO structure; timestamps are written in consecutive addresses. To read out certain addresses can be selected. Up to 64 timestamps can be stored.

Each GPIO has its own edge detection unit which can be configured to react on a rising edge, falling edge, or both. If an event occurs, the value of the timer is latchedlocally. Each pin has its own counter to count the events that have occurred, The value of this counter is stored as a "rolling number" together with the timestamp. Thus it can be easily determined if an event has been missed by looking for gaps in the rolling number when the timestamp is read. The input capture unit also stores the GPIO number at which the event occurred and the edge that triggered the event together with the timestamp data. Each detection unit can store up to one event which needs to be stored before the next event occurs.

The input capture unit needs 4 clock cycles of 125 MHz to store an event, thus the maximum frequency at which the input edges can be captured is 31.25 MHz. If multiple events happen simultaneously they are stored in the order of the GPIO pin number, i.e. GPIO1 is stored before GPIO2. If a new event happens before the event is stored the old event data is lost. As the input capture unit is shared for all pins this frequency applies to all enabled pins together. In any case, the limiting factor for edges is the speed at which the data can be read through the SMI

## 7.5.1 Input Event Control Register 7.12

The Input Event Control register is used to configure the input event unit.

| Bit | Name                    | Description   | Mode | Default |
|-----|-------------------------|---|------|---------|
| 15  | ALL_PTR_RES             | Reset all pointers  | WC   | 0       |
| 14  |                         | Reserved, ignore on read, write as 0  | R    | 0       |
| 13  | READ_WORD_NEXT          | 1: Reading next word, when accessing Read Register  | RW   | 0       |
| 40  | OVERNIA AND CORO        | 0: No impact  | DIA  |         |
| 12  | OVRRUN_ANY_GPIO         | 0: No overrun on any GPIO   | RW   | 0       |
|     |                         | 1: One of the edge detection unit got a pulse before it could handle the previous one. This means that the frequency of pulses on the GPIO is too high. |      |         |
| 11  | TIMEOUT_ANY_CHAN        | 0: No Timeout on any GPIO   | RC   | 0       |
|     |                         | 1: An edge detection unit latched an event, but it could not be stored timely. This means that the frequency of all GPIO events together is too high.   |      |         |
| 10  | TIMESTAMP_              | 1: Enable time stamping unit  | RW   | 0       |
|     | ENABLE                  | 0: Disable time stamping unit   |      |         |
| 9   | TS_<br>OVWR_EN          | 0: New timestamps can<br>overwrite older ones when<br>the buffer is full.   | RW   | 0       |
|     |                         | 1: New timestamps are not stored if memory has not been read out (no overwrite) and then buffer is full   |      |         |
| 8   | TS_RAM_<br>OVERFLOW     | 1: Timestamps were overwritten  | R    | 0       |
|     |                         | 0: Timestamps were not overwritten  |      |         |
| 6:0 | TIMESTAMP_<br>WRITE_POS | Pointer to the timestamp for<br>the next event (96 bit word<br>pointer) incremented by the<br>event manager after writing                               | R    | 0       |

#### 7.5.2 Input Capture Pin Control register 7.8

The Input Capture Pin Control register is used to enable time-stamping for GPIO 0 to 7 and is used to configure the edge on which it should trigger.

| Bit   | Name         | Description                              | Mode | Default |
|-------|--------------|--|------|---------|
| 15:14 | IN_CAP_GPIO7 | 00: Disable event timestamping for GPIO7 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 13:12 | IN_CAP_GPIO6 | 00: Disable event timestamping for GPIO6 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 11:10 | IN_CAP_GPIO5 | 00: Disable event timestamping for GPIO5 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 9:8   | IN_CAP_GPIO4 | 00: Disable event timestamping for GPIO4 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 7:6   | IN_CAP_GPIO3 | 00: Disable event timestamping for GPIO3 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 5:4   | IN_CAP_GPIO2 | 00: Disable event timestamping for GPIO2 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 3:2   | IN_CAP_GPIO1 | 00: Disable event timestamping for GPIO1 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |
| 1:0   | IN_CAP_GPIO0 | 00: Disable event timestamping for GPIO0 | RW   | 0       |
|       |              | 01: Timestamp on rising edge             |      |         |
|       |              | 10: Timestamp on falling edge            |      |         |
|       |              | 11: Timestamp on both edges              |      |         |

#### 7.5.3 Input Capture Pin Control register 7.9

The Input Capture Pin Control register is used to enable timestamping GPIO 8 to 15and is used to configure the edge on which it should trigger.

| Bit   | Name          | Description                               | Mode | Default |
|-------|---------------|---|------|---------|
| 15:14 | IN_CAP_GPIO15 | 00: Disable event timestamping for GPIO15 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 13:12 | IN_CAP_GPIO14 | 00: Disable event timestamping for GPIO14 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 11:10 | IN_CAP_GPIO13 | 00: Disable event timestamping for GPIO13 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 9:8   | IN_CAP_GPIO12 | 00: Disable event timestamping for GPIO12 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 7:6   | IN_CAP_GPIO11 | 00: Disable event timestamping for GPIO11 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 5:4   | IN_CAP_GPIO10 | 00: Disable event timestamping for GPIO10 | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 3:2   | IN_CAP_GPIO9  | 00: Disable event timestamping for GPIO9  | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |
| 1:0   | IN_CAP_GPIO8  | 00: Disable event timestamping for GPIO8  | RW   | 0       |
|       |               | 01: Timestamp on rising edge              |      |         |
|       |               | 10: Timestamp on falling edge             |      |         |
|       |               | 11: Timestamp on both edges               |      |         |

#### 7.5.4 Input Capture Pin Control register 7.10

The Input Capture Pin Control register is used to enable time-stamping for GPIO 16 to 19 and is used to configure the edge on which it should trigger.

| Bit  | Name          | Description                               | Mode | Default |
|------|---------------|---|------|---------|
| 15:8 |               | Reserved                                  | RW   | 0       |
| 7:6  | IN_CAP_GPIO19 | 00: Disable event timestamping for GPIO19 | RW   | 0       |
|      |               | 01: Timestamp on rising edge              |      |         |
|      |               | 10: Timestamp on falling edge             |      |         |
|      |               | 11: Timestamp on both edges               |      |         |
| 5:4  | IN_CAP_GPIO18 | 00: Disable event timestamping for GPIO18 | RW   | 0       |
|      |               | 01: Timestamp on rising edge              |      |         |
|      |               | 10: Timestamp on falling edge             |      |         |
|      |               | 11: Timestamp on both edges               |      |         |
| 3:2  | IN_CAP_GPIO17 | 00: Disable event timestamping for GPIO17 | RW   | 0       |
|      |               | 01: Timestamp on rising edge              |      |         |
|      |               | 10: Timestamp on falling edge             |      |         |
|      |               | 11: Timestamp on both edges               |      |         |
| 1:0  | IN_CAP_GPIO11 | 00: Disable event timestamping for GPIO16 | RW   | 0       |
|      |               | 01: Timestamp on rising edge              |      |         |
|      |               | 10: Timestamp on falling edge             |      |         |
|      |               | 11: Timestamp on both edges               |      |         |

#### 7.5.5 INPUT\_EVENT\_DATA\_READ\_WORD Register 7.15

The INPUT\_EVENT\_DATA\_READ\_WORD register gives access to the stored timestamps. To read the complete timestamp the register has to be accessed six times. The least significant word is read first. The location of the data is as follows:

| Bit   | Name                 | Description   | Mode |
|-------|----------------------|---|------|
| 95:16 | TIMESTAMP            | Timestamp of the related event described in bits 15:0.                                      | R    |
| 15:14 | BUFFER_              | 00: Timestamp buffer is empty   | R    |
|       | STATUS               | 01: Next timestamp is available   |      |
|       |                      | 10: Only two buffer for timestamp left  |      |
|       |                      | 11: Buffer is full (immediate next read required or data will be lost)                      |      |
| 13    | TIMESTAMP_<br>EDGE   | 1: Rising edge triggered the event  | R    |
|       |                      | 0: Falling edge triggered the event   |      |
| 12:8  | TIMESTAMP_<br>GPIO   | GPIO number of the pin that triggered the event   | R    |
|       |                      | 00000: GPIO0  |      |
|       |                      | 00001: GPIO1  |      |
|       |                      | 00010: GPIO2  |      |
| 7     | TIMER_ERROR          | 1: Timer overflow, the event has not been processed on time and the timestamp may be broken | R    |
|       |                      | 0: The timestamp is intact  |      |
| 6     | OVERRUN              | 1: An event was detected on the pin but could not be processed                              | R    |
|       |                      | 0: All events were processed on time  |      |
| 5:0   | TIMESTAMP_<br>NUMBER | Rolling number for events on that pin   | R    |

It may not be required to read the complete timestamp since the first words usually do not change very often, so the PHY provides a direct access to the next timestamp: the INPUT\_EVENT\_DATA\_READ\_BLOCK register will always return the LSW of the next timestamp in memory.

To read a timestamp the INPUT\_EVENT\_DATA\_BLOCK\_READ is read once and will return bits 15:0 of the next timestamp data. Then the INPUT\_EVENT\_DATA\_WORD\_READ is read up to 5 times and will return bits 31:16, bits 47:32 and so on. To get bits 15:0 of the next timestamp, read the INPUT\_EVENT\_DATA\_BLOCK\_READ. It is not required to read the complete timestamp.

## 7.5.6 INPUT\_EVENT\_DATA\_BLOCK\_READ Register 7.14

| Bit  | Name | Description  | Mode | Default |
|------|------|--|------|---------|
| 15:0 | _    | Returns the least significant word (bits 15:0) of the next timestamp | R    | 0       |

## 7.5.7 INPUT\_CAPTURE\_DATA\_POINTER Register 7.13

| Name                      | Description   | Mode   | Default  |
|---------------------------|---|--|--|
| FILLING_LEVEL             | Number of data sets in memory                             | R  | 0  |
|                           | 0: Event memory is empty                                  |  |  |
|                           | 64: Event memory is full                                  |  |  |
| TIMESTAMP_<br>READ_POS_BL | Value of the pointer to the data sets event memory        | R  | 0  |
| OCK                       | 0: Next read will read from address 0 of timestamp memory |  |  |
|                           |   |  |  |
|                           | address 63 of timestamp                                   |  |  |

#### 7.6 Pulse Generator Unit

The device has three pulse generator units which can generate pulses or events based on the PTP timer. Each can run in either of two different modes: single-shot or continuous pulse generation.

A pulse is triggered when the START\_TIME exceeds the time from the PTP timer. Although the START\_TIME has a resolution of 1/32 ns, the exact output time may be up to 8 ns later as the output signal is running on the 125 MHz clock. However, the start time is internally calculated with 1/32 ns accuracy so that the error does not accumulate.

To program a new pulse generation: disable the current pulse generation for the respective channel, write the values, and then re-enable the pulse generation by writing PULSE GO with one and setting PULSE CONFIG to the required value..

For continuous pulse the start times are calculated by taking the previous start time, adding the interval time, comparing the result to the timer, and generating the next pulse when the timer value exceeds the start time.

There are four registers which control the pulse generators. All registers are shadow registers that can be written first and are transferred to the pulse channel in PULSE\_CHANNEL at the moment the PULSE\_GO bit is set to '1'. After writing the PULSE\_CHANNEL register, these registers are updated with the actual value for this channel and can subsequently be read.

## 7.6.1 Pulse Output Control Register 7.16

The Pulse Output Control register controls the pulse units. All data written is stored for the channel selected in PULSE\_CHANNEL.

| Bit  | Name             | Description   | Mode | Default |
|------|------------------|---|------|---------|
| 15:8 |                  | Reserved, write as 0, ignore on read  | R/W  |         |
| 9    | LATCH_WIDTH      | Latch newly-written data from PULSE_WIDTH register and use for the next pulse. This bit is set after the PULSE_WIDTH register has been written and the new values should be applied. Until this is done the old value is used. This is only valid for the pulse width and the interval data. The time unit must be stopped before updating the start time.  | RW   | 0       |
| 8    | LATCH_INTERVAL   | Latch newly-written latch interval data from the PULSE_INTERVAL register and use for the next pulse. All other values remain the same. This bit is set after the PULSE_INTERVAL register has been written and the new values should be applied. Until this is done the old value is used. This is only valid for the pulse width and the interval data. The time unit must be stopped before updating the start time. | RW   | 0       |
| 7    | PULSE_GO         | Latch newly written data and use for next pulse. This bit is set after the PULSE_DATA register has been written and the new values should be used. Until this is done the old value is used. This is only valid for the pulse width and the interval data. The time unit must be stopped before updating the start time.  | RW   | 0       |
| 6    | INT_EN           | Enable interrupt for this channel An interrupt is triggered when the timer is larger than the current PULSE_STARTTIME (continuously updated according to PULSE_INTERVAL)  | RW   | 0       |
| 5    | Channel_inv      | Invert output of channel in 2:0   | RW   | 0       |
| 4:3  | PULSE_<br>CONFIG | Configuration for pulse.<br>00: Off   | RW   | 0       |

|     |                   | 01: Single shot<br>10: Continuous<br>11: Reserved  |    |   |
|-----|-------------------|--|----|---|
| 2:0 | PULSE_<br>CHANNEL | 000: Values in bits 9:3 and respective shadow registers PULSE_STARTTIME, PULSE_WIDTH and PULSE_INTERVAL will be written to channel 0 001: Values in bits 9:3 and respective shadow registers will be written to channel 1 010: Values in bits 9:3 will be written to channel 2 | RW | 0 |

#### 7.6.2 PULSE\_STARTTIME Register 7.17

The PULSE\_STARTTIME register gives the start time for the next pulse. For continuous pulses it is incremented with the PULSE\_INTERVAL value after the pulse has been triggered. The updated value can be read after writing the PULSE\_CHANNEL value. . Do not set the PULSE\_STARTTIME to a value in the past. This register has to be accessed five times with the most significant word first.

| Word | Name                        | Description   | Mode | Default |
|------|-----------------------------|---|------|---------|
| 79:0 | PULSE_<br>STARTTIME         | Actual start time for pulse. Will be updated whenever a pulse was generated and a new start time is calculated based on PULSE_INTERVAL. | R    | 0       |
| 79:0 | INITIAL_PULSE_<br>STARTTIME | Initial start time for pulse.   | W    | 0       |

## 7.6.3 PULSE\_WIDTH Register 7.19

| Bit   | Name                | Description  | Mode | Default |
|-------|---------------------|--|------|---------|
| 47:38 | PULSE_<br>WIDTH_SEC | Pulse high width seconds for single and continuous pulse.                  | RW   | 0       |
|       |                     | The shortest pulse width value is 24 ns.                                   |      |         |
| 37:5  | PULSE_<br>WIDTH_NS  | Pulse high width nanoseconds for single and continuous pulse.              | RW   | 0       |
|       |                     | The shortest pulse width value is 24 ns.                                   |      |         |
| 4:0   | PULSE_<br>WIDTH_FNS | Pulse high width fractions of nanoseconds for single and continuous pulse. | RW   | 0       |
|       |                     | The shortest pulse width value is 24 ns.                                   |      |         |

#### 7.6.4 PULSE\_INTERVAL Register 7.18

| Bit          | Name                   | Description  | Mode | Default |
|--------------|------------------------|--|------|---------|
| 47:35        | PULSE_<br>INTERVAL_SEC | Pulse interval seconds after which the next pulse is generated (only for continuous pulse).  | RW   | 0       |
|              |                        | The shortest pulse interval value is 24 ns.  |      |         |
| Bits<br>34:5 | PULSE_<br>INTERVAL_NS  | Pulse interval nanoseconds<br>after which the next pulse is<br>generated (only for continuous<br>pulse).<br>The shortest pulse interval<br>value is 24 ns. | RW   | 0       |
| Bit 4:0      | PULSE_<br>INTERVAL_FNS | Pulse interval fractions of nanoseconds after which the next pulse is generated (only for continuous pulse).  The shortest pulse interval value is 24 ns.  | RW   | 0       |

## **Electrical Characteristics**

## 8.1 AC Timing

#### 8.1.1 Serial Management Interface (SMI) Timing

Figure 1: SMI Timing

| ara-<br>meter | Description       | Min | Тур | Max | Units | Notes                |
|---------------|-------------------|-----|-----|-----|-------|----------------------|
| T1.1          | MDC to MDIO delay | 0   |     | 15  | ns    | Data output from PHY |
| T1.2          | MDC to MDIO setup | 10  |     |     | ns    |                      |
| T1.3          | MDC to MDIO hold  | 10  |     |     | ns    |                      |
|               | MDC frequency     |     |     | 25  | MHz   |                      |

#### 8.1.2 Reset Timing

Figure 2: Reset Timing

| -              | Jitter tolerance                                     |      | 20  |     | ps (rms)*1) |       |

RENESAS

<sup>\*1)</sup> Root Mean Square

#### 8.1.4 100Base-TX Timings

#### 8.1.4.1 100M MII Receive Timing

Figure 3: 100BT MII receive timing

| Para-<br>meter | Description  | Min | Тур | Max | Units | Notes  |
|----------------|--|-----|-----|-----|-------|--|
| T3.1           | Received<br>signals output<br>delay after<br>rising edge of<br>PnRXCLK | 15  |     | 27  | ns    |  |
| T3.2           | Start of RX-bit<br>to PnRXDV<br>valid                                  |     | 170 |     | ns    | RX_DV_J2T<br>(Register<br>PHY.31.1)<br>set     |
|                |  |     | 210 |     | ns    | RX_DV_J2T<br>(Register<br>PHY.31.1)<br>cleared |
|                | PnRXCLK frequency  |     | 25  |     | MHz   |  |
|                | PnRXCLK<br>duty-cycle  | 45  | 50  | 55  | %     |  |

<sup>\*1)</sup> Note that glitch may occur on output signals between min and max value of T3.1 after rising edge of P\*RXCLK. However, it is compliant with IEEE802.3 standard because the setup time at the input of MAC is 13ns (=Period 40ns - max value > 10ns) and the hold time is 15ns (= min value > 10ns).
