DESCRIPTION

The MC34063C is a monolithic switching regulator control circuit containing the primary function required for DC-DC converters.

This device consists of internal temperature compensated reference, voltage comparator, and duty cycle oscillator with active current. The device is specifically designed to be used in Step-Step-Up and Voltage-Inverting applications with a minimum number of external components.

The MC34063C is the enhanced version of MC34063A with the ability to work in higher frequency. The MC34063C is available in 2 packages : SOP-8 and DIP-8.

Notes:

- 1 Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "Recommended Operating Conditions" is not implied. Exposure to "Absolute Maximum Ratings" for extended periods may affect device reliability.
- 2 Maximum package power dissipation limits must be observed.
- 3 Low duty cycle pulse technique are used during test to maintain junction temperature as close to ambient temperature as possible.
- 4 If the output switch is driven into hard saturation (non-Darlington configuration) at low switch currents ($\leq 300mA$) and high driver currents ($\geq 30mA$), it may take up to $2.0\mu s$ for it to come out of saturation. This condition will shorten the off time at frequencies 30kHz, and is magnified at high temperatures. This condition does not occur with a Darlington configuration, since the output switch cannot saturate.
