# Chapter 1: LPC1315/16/17/45/46/47 Introductory information

Rev. 4 — 12 March 2013

**User manual** 

### 1.1 Introduction

The LPC1315/16/17/45/46/47 are ARM Cortex-M3 based microcontrollers for embedded applications featuring a high level of integration and low power consumption. The ARM Cortex-M3 is a next generation core that offers system enhancements such as enhanced debug features and a higher level of support block integration.

The LPC1315/16/17/45/46/47 operate at CPU frequencies of up to 72 MHz. The ARM Cortex-M3 CPU incorporates a 3-stage pipeline and uses a Harvard architecture with separate local instruction and data buses as well as a third bus for peripherals. The ARM Cortex-M3 CPU also includes an internal prefetch unit that supports speculative branching.

Equipped with a highly flexible and configurable Full-Speed USB 2.0 device controller available on the LPC1345/46/47, this series brings unparalleled design flexibility and seamless integration to today's demanding connectivity solutions.

The peripheral complement of the LPC1315/16/17/45/46/47 includes up to 64 kB of flash memory, 8 kB or 10 kB of SRAM data memory, one Fast-mode Plus I<sup>2</sup>C-bus interface, one RS-485/EIA-485 USART with support for synchronous mode and smart card interface, two SSP interfaces, four general purpose counter/timers, an 8-channel, 12-bit ADC, and up to 51 general purpose I/O pins.

#### 1.2 Features

#### System:

ARM Cortex-M3 r2p1 processor, running at frequencies of up to 72 MHz. ARM Cortex-M3 built-in Nested Vectored Interrupt Controller (NVIC). Non Maskable Interrupt (NMI) input selectable from several input sources. System tick timer.

#### Memory:

- Up to 64 kB on-chip flash program memory with a 256 byte page erase function.
- In-System Programming (ISP) and In-Application Programming (IAP) via on-chip bootloader software. Flash updates via USB supported.
- Up to 4 kB on-chip EEPROM data memory with on-chip API support.
- Up to 12 kB SRAM data memory.
- 16 kB boot ROM with API support for USB API, power control, EEPROM, and flash IAP/ISP.

#### Chapter 1: LPC1315/16/17/45/46/47 Introductory information

#### · Debug options:

- Standard JTAG test interface for BSDL.
- Serial Wire Debug.
- Support for ETM ARM Cortex-M3 debug time stamping.

#### Digital peripherals:

- Up to 51 General Purpose I/O (GPIO) pins with configurable pull-up/pull-down resistors, repeater mode, input inverter, and pseudo open-drain mode. Eight pins support programmable glitch filter.
- Up to 8 GPIO pins can be selected as edge and level sensitive interrupt sources.
- Two GPIO grouped interrupt modules enable an interrupt based on a programmable pattern of input states of a group of GPIO pins.
- High-current source output driver (20 mA) on one pin (P0\_7).
- High-current sink driver (20 mA) on true open-drain pins (P0\_4 and P0\_5).
- Four general purpose counter/timers with a total of up to 8 capture inputs and 13 match outputs.
- Programmable Windowed WatchDog Timer (WWDT) with a internal low-power WatchDog Oscillator (WDO).
- Repetitive Interrupt Timer (RI Timer).

#### Analog peripherals:

- 12-bit ADC with eight input channels and sampling rates of up to 500 kSamples/s.

#### Serial interfaces:

- USB 2.0 full-speed device controller (LPC1345/46/47) with on-chip ROM-based USB driver library.
- USART with fractional baud rate generation, internal FIFO, a full modem control handshake interface, and support for RS-485/9-bit mode and synchronous mode. USART supports an asynchronous smart card interface (ISO 7816-3).
- Two SSP controllers with FIFO and multi-protocol capabilities.
- I<sup>2</sup>C-bus interface supporting the full I<sup>2</sup>C-bus specification and Fast-mode Plus with a data rate of up to 1 Mbit/s with multiple address recognition and monitor mode.

#### · Clock generation:

- Crystal Oscillator with an operating range of 1 MHz to 25 MHz (system oscillator) with failure detector.
- 12 MHz high-frequency Internal RC oscillator (IRC) trimmed to 1 % accuracy over the entire voltage and temperature range. The IRC can optionally be used as a system clock.
- Internal low-power, low-frequency WatchDog Oscillator (WDO) with programmable frequency output.
- PLL allows CPU operation up to the maximum CPU rate with the system oscillator or the IRC as clock sources.
- A second, dedicated PLL is provided for USB (LPC1345/46/47).
- Clock output function with divider that can reflect the crystal oscillator, the main clock, the IRC, or the watchdog oscillator.
- Power control:

#### Chapter 1: LPC1315/16/17/45/46/47 Introductory information

- Four reduced power modes: Sleep, Deep-sleep, Power-down, and Deep power-down.
- Power profiles residing in boot ROM allow optimized performance and minimized power consumption for any given application through one simple function call.
- Processor wake-up from Deep-sleep and Power-down modes via reset, selectable GPIO pins, watchdog interrupt, or USB port activity.
- Processor wake-up from Deep power-down mode using one special function pin.
- Integrated PMU (Power Management Unit) to minimize power consumption during Sleep, Deep-sleep, Power-down, and Deep power-down modes.
- Power-On Reset (POR).
- Brownout detect with four separate thresholds for interrupt and forced reset.
- Unique device serial number for identification.
- Single 3.3 V power supply (2.0 V to 3.6 V).
- Temperature range -40 °C to +85 °C.
- Available as LQFP64, LQFP48, and HVQFN33 package.

# 1.3 Ordering information

Table 1. Ordering information

Type number	Package		
	Name	Description	Version
LPC1345FHN33	HVQFN33	plastic thermal enhanced very thin quad flat package; no leads; 33 terminals; body 7 $\times$ 7 $\times$ 0.85 mm	n/a
LPC1345FBD48	LQFP48	plastic low profile quad flat package; 48 leads; body $7 \times 7 \times 1.4 \text{ mm}$	SOT313-2

# 2.2 Memory map

The LPC1315/16/17/45/46/47 incorporates several distinct memory regions, shown in the following figures. Figure 2 shows the overall map of the entire address space from the user program viewpoint following reset.

The AHB peripheral area is 2 MB in size and is divided to allow for up to 128 peripherals. The APB peripheral area is 512 kB in size and is divided to allow for up to 32 peripherals. Each peripheral of either type is allocated 16 kB of space. This allows simplifying the address decoding for each peripheral.

### 2.2.1 On-chip flash programming memory

The LPC1315/16/17/45/46/47 contain up to 128 kB on-chip flash program memory. The flash can be programmed using In-System Programming (ISP) or In-Application Programming (IAP) via the on-chip boot loader software. Flash updates via USB are supported as well.

The flash memory is divided into 4 kB sectors with each sector consisting of 16 pages. Individual pages of 256 byte each can be erased using the IAP erase page command.

#### Chapter 2: LPC1315/16/17/45/46/47 Memory mapping

#### **2.2.2 EEPROM**

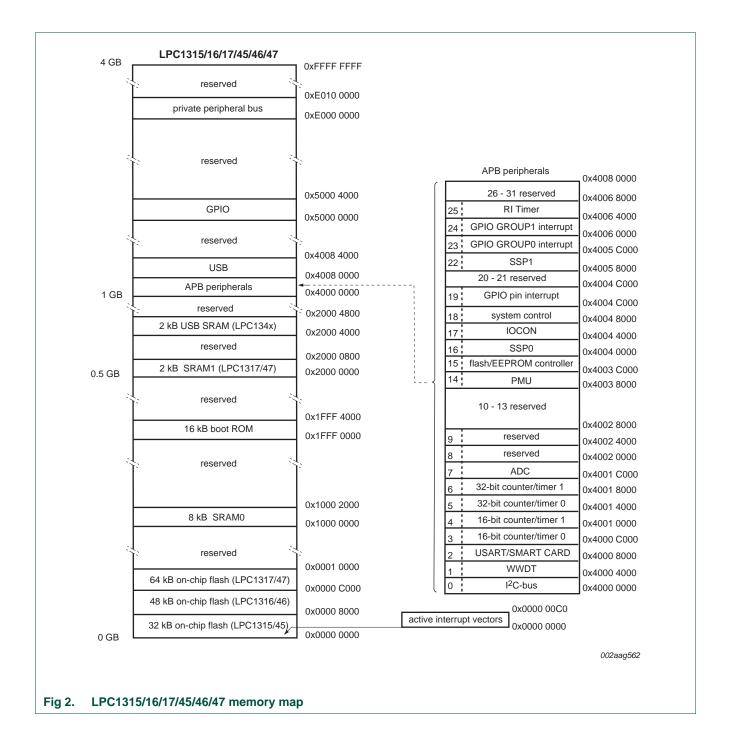

The LPC1315/16/17/45/46/47 contain 2 kB or 4 kB of on-chip byte-erasable and byte-programmable EEPROM data memory. The EEPROM can be programmed using In-Application Programming (IAP) via the on-chip boot loader software.

#### 2.2.3 **SRAM**

The LPC1315/16/17/45/46/47 contain a total of 8 kB, 10 kB, or 12 kB on-chip static RAM memory. The USB SRAM block is available on parts LPC134x only. SRAM block SRAM1 is available on parts LPC1347/17 only.

The SRAM1 and USB SRAM clocks are turned off by default. Enable the clocks in the SYSHBCLKCTRL register (Table 19).

**User manual** 

# 3.1 How to read this chapter

All USB-related registers and register bits are available on parts LPC134x only. The USB PLL is available on parts LPC134x only.

**Remark:** The DEVICE\_ID register is located at address offset 0x3F8. This register location is different from other LPC1xxx parts.

# 3.2 Introduction

The system configuration block controls oscillators, some aspects of the power management, and the clock generation of the LPC1315/16/17/45/46/47. Also included in this block is a register for remapping flash, SRAM, and ROM memory areas.

# 3.3 Pin description

Table 4 shows pins that are associated with system control block functions.

Table 4. Pin summary

Pin name	Pin direction	Pin description
CLKOUT	0	Clockout pin
PIO0 and PIO1 pins	l	Eight pins can be selected as external interrupt pins from all available GPIO pins (see <u>Table 35</u> ).

# 3.4 Clocking and power control

See Figure 3 for an overview of the LPC1315/16/17/45/46/47 Clock Generation Unit (CGU).

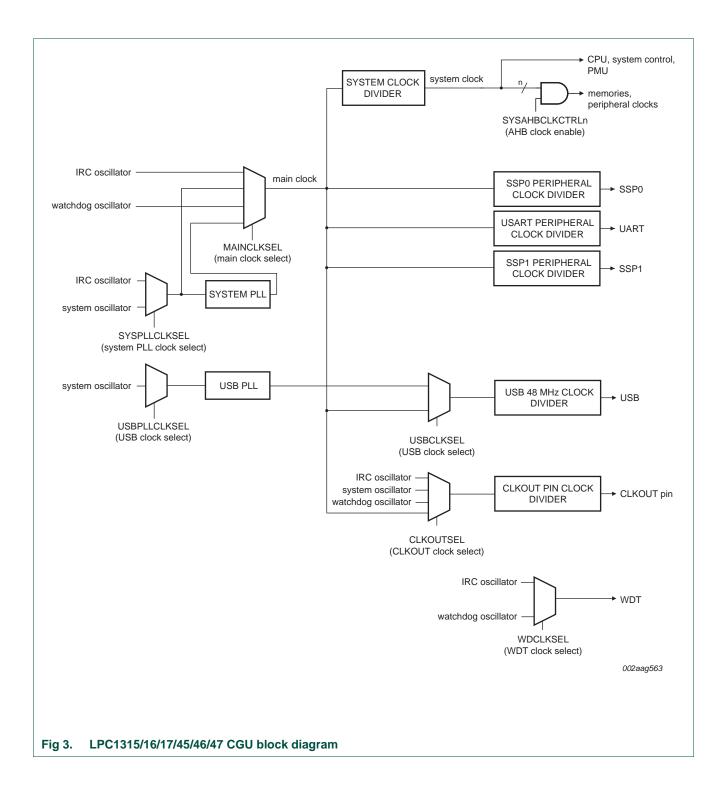

The LPC1315/16/17/45/46/47 include three independent oscillators. These are the system oscillator, the Internal RC oscillator (IRC), and the Watchdog oscillator. Each oscillator can be used for more than one purpose as required in a particular application.

Following reset, the LPC1315/16/17/45/46/47 will operate from the Internal RC oscillator until switched by software. This allows systems to operate without an external crystal and the bootloader code to operate at a known frequency.

The SYSAHBCLKCTRL register gates the system clock to the various peripherals and memories. USART and SSP have individual clock dividers to derive peripheral clocks from the main clock.

The main clock, and the clock outputs from the IRC, the system oscillator, and the watchdog oscillator can be observed directly on the CLKOUT pin.

# 3.5.1 System memory remap register (SYSMEMREMAP)

The system memory remap register selects whether the exception vectors are read from boot ROM, flash, or SRAM. By default, the flash memory is mapped to address 0x0000 0000. When the MAP bits in the SYSMEMREMAP register are set to 0x0 or 0x1, the boot ROM or RAM respectively are mapped to the bottom 512 bytes of the memory map (addresses 0x0000 0000 to 0x0000 0200).

Table 6. System memory remap (SYSMEMREMAP, address 0x4004 8000) bit description

Bit	Symbol	Value	Description	Reset value	
1:0	MAP		System memory remap. Value 0x3 is reserved.	0x2	
		0x0	Boot Loader Mode. Interrupt vectors are re-mapped to Boot ROM.		
			0x1	User RAM Mode. Interrupt vectors are re-mapped to Static RAM.	
		0x2	User Flash Mode. Interrupt vectors are not re-mapped and reside in Flash.		
31:2	-		Reserved	-	

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

# 3.5.2 Peripheral reset control register (PRESETCTRL)

This register allows software to reset specific peripherals. A 0 in an assigned bit in this register resets the specified peripheral. A 1 negates the reset and allows peripheral operation.

**Remark:** Before accessing the SSP and I2C peripherals, write a 1 to this register to ensure that the reset signals to the SSP and I2C are de-asserted.

Table 7. Peripheral reset control (PRESETCTRL, address 0x4004 0004) bit description

Bit	Symbol	Value	Description	Reset value
0	SSP0_RST_N		SSP0 reset control	0
		0	Resets the SSP0 peripheral.	
		1	SSP0 reset de-asserted.	
1	I2C_RST_N		I2C reset control	0
		0	Resets the I2C peripheral.	
		1	I2C reset de-asserted.	
2	SSP1_RST_N		SSP1 reset control	0
		0	Resets the SSP0 peripheral.	
		1	SSP1 reset de-asserted.	
3	-		Reserved	-
31:4	-		Reserved	-

# 3.5.3 System PLL control register (SYSPLLCTRL)

This register connects and enables the system PLL and configures the PLL multiplier and divider values. The PLL accepts an input frequency from 10 MHz to 25 MHz from various clock sources. The input frequency is multiplied to a higher frequency and then divided down to provide the actual clock used by the CPU, peripherals, and memories. The PLL can produce a clock up to the maximum allowed for the CPU.

Table 8. System PLL control (SYSPLLCTRL, address 0x4004 8008) bit description

Bit	Symbol	Value	Description	Reset value

# 3.5.5 USB PLL control register (USBPLLCTRL)

The USB PLL is identical to the system PLL and is used to provide a dedicated clock to the USB block if available (see Section 3.1).

This register connects and enables the USB PLL and configures the PLL multiplier and divider values. The PLL accepts an input frequency from 10 MHz to 25 MHz from various clock sources. The input frequency is multiplied up to a high frequency, then divided down to provide the actual clock 48 MHz clock used by the USB subsystem.

Table 10. USB PLL control (USBPLLCTRL, address 0x4004 8010) bit description

Bit	Symbol	Value	Description	Reset value
4:0	MSEL		Feedback divider value. The division value M is the programmed MSEL value $+$ 1. 00000: Division ratio M = 1 to 11111: Division ratio M = 32	0x000
6:5	PSEL		Post divider ratio P. The division ratio is 2 x P.	0x00
		0x0	P = 1	
		0x1	P = 2	
		0x2	P = 4	
		0x3	P = 8	
31:7	-		Reserved. Do not write ones to reserved bits.	0x00

# 3.5.6 USB PLL status register (USBPLLSTAT)

This register is a Read-only register and supplies the PLL lock status (see Section 3.10.1).

# 3.5.7 System oscillator control register (SYSOSCCTRL)

This register configures the frequency range for the system oscillator.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Bit **Symbol** Value Description Reset value **BYPASS** 0 Bypass system oscillator 0x0 0 Oscillator is not bypassed. 1 Bypass enabled. PLL input (sys\_osc\_clk) is fed directly from the XTALIN pin bypassing the oscillator. Use this mode when using an external clock source instead of the crystal oscillator. 1 **FREQRANGE** Determines frequency range for Low-power oscillator. 0x0 0 1 - 20 MHz frequency range.

15 - 25 MHz frequency range

Reserved

Table 12. System oscillator control (SYSOSCCTRL, address 0x4004 8020) bit description

# 3.5.8 Watchdog oscillator control register

31:2

1

This register configures the watchdog oscillator. The oscillator consists of an analog and a digital part. The analog part contains the oscillator function and generates an analog clock (Fclkana). With the digital part, the analog output clock (Fclkana) can be divided to the required output clock frequency wdt\_osc\_clk. The analog output frequency (Fclkana) can be adjusted with the FREQSEL bits between 600 kHz and 4.6 MHz. With the digital part Fclkana will be divided (divider ratios = 2, 4,...,64) to wdt\_osc\_clk using the DIVSEL bits.

The output clock frequency of the watchdog oscillator can be calculated as  $wdt_osc_clk = Fclkana/(2 \times (1 + DIVSEL)) = 9.3 kHz$  to 2.3 MHz (nominal values).

**Remark:** Any setting of the FREQSEL bits will yield a Fclkana value within  $\pm 40\%$  of the listed frequency value. The watchdog oscillator is the clock source with the lowest power consumption. If accurate timing is required, use the IRC or system oscillator.

**Remark:** The frequency of the watchdog oscillator is undefined after reset. The watchdog oscillator frequency must be programmed by writing to the WDTOSCCTRL register before using the watchdog oscillator.

Table 13. Watchdog oscillator control register (WDTOSCCTRL, address 0x4004 8024) bit description

**User manual** 

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

# 3.5.20 USB clock source select register (USBCLKSEL)

This register selects the clock source for the USB usb\_clk. The clock source can be either the USB PLL output or the main clock, and the clock can be further divided by the USBCLKDIV register (see Table 26) to obtain a 48 MHz clock.

**Remark:** When switching clock sources, both clocks must be running before the clock source is updated. The default clock source for the USB controller is the USB PLL output. For switching the clock source to the main clock, ensure that the system PLL and the USB PLL are running to make both clock sources available for switching. The main clock must be set to 48 MHz and configured with the main PLL and the system oscillator. After the switch, the USB PLL can be turned off.

Table 25. USB clock source select (USBCLKSEL, address 0x4004 80C0) bit description

Bit	Symbol	Value	Description	Reset value
1:0 SEL	SEL	SEL	USB clock source. Values 0x2 and 0x3 are reserved.	0x00
		0x0	USB PLL out	
		0x1	Main clock	
31:2	-		Reserved	0x00

# 3.5.21 USB clock source divider register (USBCLKDIV)

This register allows the USB clock usb\_clk to be divided to 48 MHz. The usb\_clk can be shut down by setting the DIV bits to 0x0.

Table 26. USB clock source divider (USBCLKDIV, address 0x4004 80C8) bit description

Bit	Symbol	Description	Reset value
7:0	DIV	USB clock divider values 0: Disable USB clock. 1: Divide by 1. to 255: Divide by 255.	0x01
31:8	-	Reserved	0x00

# 3.5.22 CLKOUT clock source select register (CLKOUTSEL)

This register selects the signal visible on the CLKOUT pin. Any oscillator or the main clock can be selected.

To change the clock source visible on the CLKOUT pin, first enable the new clock source with the currently selected clock source still running, change the clock source using the SEL bit, and then remove the current clock source.

If the clock source selected on the CLKOUT pin is powered down in the PDRUNCFG or PDSLEEPCFG registers, this same clock source must be re-enabled before another clock source can be selected through this register.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Table 27. CLKOUT clock source select (CLKOUTSEL, address 0x4004 80E0) bit description

Bit	Symbol	Value	Description	Reset value

31:8	-	Reserved	-

# 3.5.24 POR captured PIO status 0 register (PIOPORCAP0)

The PIOPORCAP0 register captures the state of GPIO port 0 at power-on-reset. Each bit represents the reset state of one GPIO pin. This register is a read-only status register.

Table 29. POR captured PIO status 0 (PIOPORCAP0, address 0x4004 8100) bit description

Bit	Symbol	Description	Reset value
23:0	PIOSTAT	State of P0_23 through P0_0 at power-on reset	Implementation dependent
31:24	-	Reserved	-

# 3.5.25 POR captured PIO status 1 register (PIOPORCAP1)

The PIOPORCAP1 register captures the state of GPIO port 1 at power-on-reset. Each bit represents the reset state of one GPIO pin. This register is a read-only status register.

Table 30. POR captured PIO status 1 (PIOPORCAP1, address 0x4004 8104) bit description

Bit	Symbol	Description	Reset value
31:0	PIOSTAT	State of P1_31 through P1_0 at power-on reset	Implementation dependent

# 3.5.26 Brown-Out Detect register (BODCTRL)

The BOD control register selects up to four separate threshold values for sending a BOD interrupt to the NVIC and for forced reset. Reset and interrupt threshold values listed in <a href="Table 31">Table 31</a> are typical values.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Both the BOD interrupt and the BOD reset, depending on the value of bit BODRSTENA in this register, can wake-up the chip from Sleep, Deep-sleep, and Power-down modes. See Section 3.9.

Table 31. Brown-Out Detect (BODCTRL, address 0x4004 8150) bit description

Bit	Symbol	Value	Description	Reset value	
1:0	BODRSTLEV		BOD reset level	00	
		0x0	Level 0: The reset assertion threshold voltage is 1.46 V; the reset de-assertion threshold voltage is 1.63 V.		
		0x1	Level 1: The reset assertion threshold voltage is 2.06 V; the reset de-assertion threshold voltage is 2.15 V.		
		0x2	Level 2: The reset assertion threshold voltage is 2.35 V; the reset de-assertion threshold voltage is 2.43 V.		
		0x3	Level 3: The reset assertion threshold voltage is 2.63 V; the reset de-assertion threshold voltage is 2.71 V.		
3:2	BODINTVAL		BOD interrupt level	00	
		0x0	Reserved.		
		0x1	Level 1:The interrupt assertion threshold voltage is 2.22 V; the interrupt de-assertion threshold voltage is 2.35 V.		
		0x2	Level 2: The interrupt assertion threshold voltage is 2.52 V; the interrupt de-assertion threshold voltage is 2.66 V.		
		0x3	Level 3: The interrupt assertion threshold voltage is 2.80 V; the interrupt de-assertion threshold voltage is 2.90 V.		
4	BODRSTENA		BOD reset enable	0	
		0	Disable reset function.		
		1	Enable reset function.		
31:5	-		Reserved	0x00	

# 3.5.27 System tick counter calibration register (SYSTCKCAL)

This register determines the value of the SYST\_CALIB register (see Table 323).

Table 32. System tick counter calibration (SYSTCKCAL, address 0x4004 8154) bit description

Bit	Symbol	Description	Reset value
25:0	CAL	System tick timer calibration value	
31:26	-	Reserved	-

# 3.5.28 IQR delay register (IRQLATENCY)

The IRQLATENCY register is an 8-bit register which specifies the minimum number of cycles (0-255) permitted for the system to respond to an interrupt request. The intent of this register is to allow the user to select a trade-off between interrupt response time and determinism.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Setting this parameter to a very low value (e.g. zero) will guarantee the best possible interrupt performance but will also introduce a significant degree of uncertainty and jitter. Requiring the system to always take a larger number of cycles (whether it needs it or not) will reduce the amount of uncertainty but may not necessarily eliminate it.

Theoretically, the ARM Cortex-M3 core should always be able to service an interrupt request within 15 cycles. System factors external to the cpu, however, bus latencies, peripheral response times, etc. can increase the time required to complete a previous instruction before an interrupt can be serviced. Therefore, accurately specifying a minimum number of cycles that will ensure determinism will depend on the application.

The default setting for this register is 0x010.

Table 33. IQR delay (IRQLATENCY, address 0x4004 8170) bit description

Bit	Symbol	Description	Reset value
7:0	LATENCY	8-bit latency value	0x010
31:8	-	Reserved	-

# 3.5.29 NMI Source Control register (NMISRC)

The NMI source selection register selects a peripheral interrupts as source for the NMI interrupt of the ARM Cortex-M3 core. For a list of all peripheral interrupts and their IRQ numbers see <u>Table 53</u>. For a description of the NMI functionality, see *ARM Cortex-M3 technical reference manual*.

**Remark:** When you want to change the interrupt source for the NMI, you must first disable the NMI source by setting bit 31 in this register to 0. Then change the source by updating the IRQN bits and re-enable the NMI source by setting bit 31 to 1.

Table 34. NMI Source Control (NMISRC, address 0x4004 8174) bit description

Bit	Symbol	Description	Reset value
4:0	IRQN	The IRQ number of the interrupt that acts as the Non-Maskable Interrupt (NMI) if bit 31 is 1. See <u>Table 53</u> for the list of interrupt sources and their IRQ numbers.	0
30:5	-	Reserved	-
31	NMIEN	Write a 1 to this bit to enable the Non-Maskable Interrupt (NMI) source selected by bits 4:0.	0

**Remark:** If the NMISRC register is used to select an interrupt as the source of Non-Maskable interrupts, and the selected interrupt is enabled, one interrupt request can result in both a Non-Maskable and a normal interrupt. This can be avoided by disabling the normal interrupt in the NVIC, as described in the *ARM Cortex-M3 technical reference manual*.

### 3.5.30 GPIO Pin Interrupt Select register (PINTSEL0 to 7)

Each of these 8 registers selects one GPIO pin from all GPIO pins on both ports as the source of a pin interrupt. To select a pin for any of the eight pin interrupts, write the pin number as 0 to 23 for pins PIO0\_0 to PIO0\_23 and 24 to 55 for pins PIO1\_0 to PIO1\_31

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

to the INTPIN bits. For example, setting INTPIN to 0x5 in PINTSEL0 selects pin PIO0\_5 for pin interrupt 0. Setting INTPIN in PINTSEL7 to 0x32 (pin 50) selects pin PIO1\_26 for pin interrupt 7.

Each of the 8 pin interrupts must be enabled in the NVIC using interrupt slots # 0 to 7 (see Table 53).

To enable each pin interrupt and configure its edge or level sensitivity, use the GPIO pin interrupt registers (see Section 9.4.1).

Table 35. GPIO Pin Interrupt Select register (PINTSEL0 to 7, address 0x4004 8178 (PINTSEL0) to 0x4004 8194 (PINTSEL7)) bit description

	` `		, , ,

# 3.5.31 USB clock control register (USBCLKCTRL)

This register controls the use of the USB need\_clock signal and the polarity of the need\_clock signal for triggering the USB wake-up interrupt. For details of how to use the USB need\_clock signal for waking up the part from Deep-sleep or Power-down modes, see Section 10.7.6.

Table 36. USB clock control (USBCLKCTRL, address 0x4004 8198) bit description

Bit	Symbol	Value	Description	Reset value	
0	AP_CLK		USB need_clock signal control	0x0	
		0	Under hardware control.		
		1	Forced HIGH.		
1	POL_CLK		USB need_clock polarity for triggering the USB wake-up interrupt	0x0	
		0	Falling edge of the USB need_clock triggers the USB wake-up (default).		
		1	Rising edge of the USB need_clock triggers the USB wake-up.		
31:2	-		Reserved	0x00	

# 3.5.32 USB clock status register (USBCLKST)

This register is read-only and returns the status of the USB need\_clock signal. For details of how to use the USB need\_clock signal for waking up the part from Deep-sleep or Power-down modes, see <a href="Section 10.7.6">Section 10.7.6</a>.

# 3.5.34 Start logic 1 interrupt wake-up enable register (STARTERP1)

This register selects which interrupts will wake the part from deep-sleep and power-down modes. Interrupts selected by a one in these registers must be enabled in the NVIC (Table 53).

The STARTERP1 register enables the WWDT interrupt, the BOD interrupt, the USB wake-up interrupt and the two GPIO group interrupts for wake-up.

Table 39. Start logic 1 interrupt wake-up enable register (STARTERP1, address 0x4004 8214) bit description

# 3.5.35 Deep-sleep mode configuration register (PDSLEEPCFG)

The bits in this register (BOD\_PD and WDTOSC\_OD) can be programmed to control aspects of Deep-sleep and Power-down modes. The bits are loaded into corresponding bits of the PDRUNCFG register when Deep-sleep mode or Power-down mode is entered.

**Remark:** Hardware forces the analog blocks to be powered down in Deep-sleep and Power-down modes according to the power configuration described in <u>Section 3.9.4.1</u> and <u>Section 3.9.5.1</u>. An exception are the exception of BOD and watchdog oscillator, which can be configured to remain running through this register. The WDTOSC\_PD value written to the PDSLEEPCFG register is overwritten if the LOCK bit in the WWDT MOD register (see <u>Table 269</u>) is set. See <u>Section 15.7</u> for details.

### Chapter 3: LPC1315/16/17/45/46/47 System control block

# 3.5.37 Power configuration register (PDRUNCFG)

The PDRUNCFG register controls the power to the various analog blocks. This register can be written to at any time while the chip is running, and a write will take effect immediately with the exception of the power-down signal to the IRC.

To avoid glitches when powering down the IRC, the IRC clock is automatically switched off at a clean point. Therefore, for the IRC a delay is possible before the power-down state takes effect.

Table 42. Power configuration register (PDRUNCFG, address 0x4004 8238) bit description

### 3.6 Reset

Reset has four sources on the LPC1315/16/17/45/46/47: the RESET pin, Watchdog Reset, Power-On Reset (POR), and Brown Out Detect (BOD). In addition, there is an ARM software reset.

The RESET pin is a Schmitt trigger input pin. Assertion of chip Reset by any source, once the operating voltage attains a usable level, starts the IRC causing reset to remain asserted until the external Reset is de-asserted, the oscillator is running, and the flash controller has completed its initialization.

On the assertion of any reset source (Arm software reset, POR, BOD reset, External reset, and Watchdog reset), the following processes are initiated:

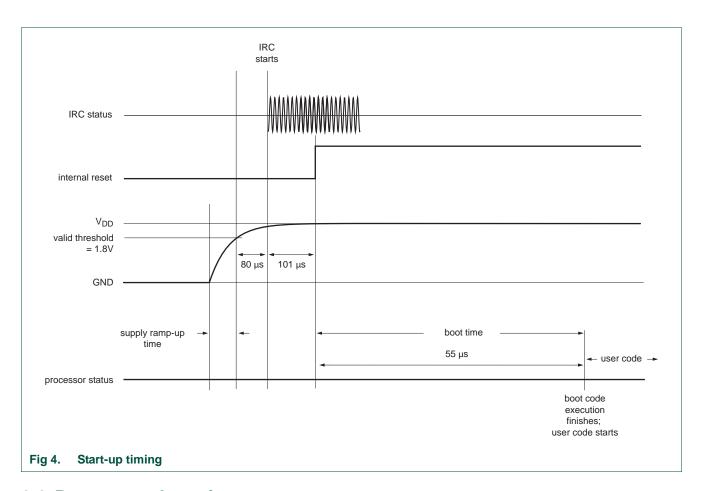

- 1. The IRC starts up. After the IRC-start-up time (maximum of 6  $\mu$ s on power-up), the IRC provides a stable clock output.
- 2. The boot code in the ROM starts. The boot code performs the boot tasks and may jump to the flash.
- 3. The flash is powered up. This takes approximately  $100 \mu s$ . Then the flash initialization sequence is started, which takes about 250 cycles.

When the internal Reset is removed, the processor begins executing at address 0, which is initially the Reset vector mapped from the boot block. At that point, all of the processor and peripheral registers have been initialized to predetermined values.

# 3.7 Start-up behavior

See <u>Figure 4</u> for the start-up timing after reset. The IRC is the default clock at Reset and provides a clean system clock shortly after the supply voltage reaches the threshold value of 1.8 V.

# Chapter 3: LPC1315/16/17/45/46/47 System control block

### 3.8 Brown-out detection

The LPC1315/16/17/45/46/47 includes up to four levels for monitoring the voltage on the  $V_{DD}$  pin. If this voltage falls below one of the selected levels, the BOD asserts an interrupt signal to the NVIC or issues a reset, depending on the value of the BODRSTENA bit in the BOD control register (Table 31).

The interrupt signal can be enabled for interrupt in the Interrupt Enable Register in the NVIC (see <u>Table 348</u>) in order to cause a CPU interrupt; if not, software can monitor the signal by reading a dedicated status register.

If the BOD interrupt is enabled in the STARTERP1 register (see <u>Table 39</u>) and in the NVIC, the BOD interrupt can wake up the chip from Deep-sleep and power-down mode.

If the BOD reset is enabled, the forced BOD reset can wake up the chip from Deep-sleep or Power-down mode.

# Chapter 3: LPC1315/16/17/45/46/47 System control block

# 3.9 Power management

The LPC1315/16/17/45/46/47 support a variety of power control features. In Active mode, when the chip is running, power and clocks to selected peripherals can be optimized for power consumption. In addition, there are four special modes of processor power reduction with different peripherals running: Sleep mode, Deep-sleep mode, Power-down mode, and Deep power-down mode.

Table 44.	Peripheral	configuration i	n reduced	power modes

Peripheral	Sleep mode	Deep-sleep mode	Power-down mode	Deep power-down mode
IRC	software configurable	on	off[1]	off
IRC output	software configurable	off[1]	off <u>[1]</u>	off
Flash	software configurable	on	off	off
BOD	software configurable	software configurable	software configurable	off
PLL	software configurable	off	off	off
SysOsc	software configurable	off	off	off
WDosc/WWDT	software configurable	software configurable	software configurable	off
ADC	software configurable	off	off	off
Digital peripherals	software configurable	off	off	off
USB	software configurable	off	off	off

<sup>[1]</sup> If bit 5, the clock source lock bit, in the WWDT MOD register is set and the IRC is selected as the WWDT clock source, the IRC and the IRC output are forced on during this mode (Table 274). This increases power consumption and may cause the part not to enter Power-down mode correctly. For details see Section 15.7.

**Remark:** The Debug mode is not supported in Sleep, Deep-sleep, Power-down, or Deep power-down modes.

### 3.9.1 Reduced power modes and WWDT lock features

The WWDT clock select lock feature influences the power consumption in any of the power modes because locking the WWDT clock source forces the selected WWDT clock source to be on, independently of the Deep-sleep and Power-down mode software configuration through the PDSLEEPCFG register. For details see <u>Section 15.7</u>.

If the part uses Deep-sleep mode with the WWDT running, the watchdog oscillator is the preferred clock source as it minimizes power consumption. If the clock source is not locked, the watchdog oscillator must be powered by using the PDSLEEPCFG register. Alternatively, the IRC may be selected and locked in WWDT MOD register, which forces the IRC on during Deep-sleep mode.

If the part uses Power-down mode with the WWDT running, the watchdog oscillator must be selected as the clock source. If the clock source is not locked, the watchdog oscillator must be powered by using the PDSLEEPCFG register. Do not lock the clock source with the IRC selected.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

#### 3.9.2 Active mode

In Active mode, the ARM Cortex-M3 core and memories are clocked by the system clock, and peripherals are clocked by the system clock or a dedicated peripheral clock.

The chip is in Active mode after reset and the default power configuration is determined by the reset values of the PDRUNCFG and SYSAHBCLKCTRL registers. The power configuration can be changed during run time.

#### 3.9.2.1 Power configuration in Active mode

Power consumption in Active mode is determined by the following configuration choices:

- The SYSAHBCLKCTRL register controls which memories and peripherals are running (Table 19).
- The power to various analog blocks (PLL, oscillators, the ADC, the BOD circuit, and the flash block) can be controlled at any time individually through the PDRUNCFG register (Table 42).
- The clock source for the system clock can be selected from the IRC (default), the system oscillator, or the watchdog oscillator (see <a href="Figure 3">Figure 3</a> and related registers).
- The system clock frequency can be selected by the SYSPLLCTRL (Table 8) and the SYSAHBCLKDIV register (Table 18).
- Selected peripherals (USART, SSP0/1, USB, CLKOUT) use individual peripheral clocks with their own clock dividers. The peripheral clocks can be shut down through the corresponding clock divider registers (Table 20 to Table 24).

#### 3.9.3 Sleep mode

In Sleep mode, the system clock to the ARM Cortex-M3 core is stopped, and execution of instructions is suspended until either a reset or an interrupt occurs.

Peripheral functions, if selected to be clocked in the SYSAHBCLKCTRL register, continue operation during Sleep mode and may generate interrupts to cause the processor to resume execution. Sleep mode eliminates dynamic power used by the processor itself, memory systems and related controllers, and internal buses. The processor state and registers, peripheral registers, and internal SRAM values are maintained, and the logic levels of the pins remain static.

#### 3.9.3.1 Power configuration in Sleep mode

Power consumption in Sleep mode is configured by the same settings as in Active mode:

- The clock remains running.
- The system clock frequency remains the same as in Active mode, but the processor is not clocked.
- Analog and digital peripherals are selected as in Active mode.

#### 3.9.3.2 Programming Sleep mode

The following steps must be performed to enter Sleep mode:

- 1. The PD bits in the PCON register must be set to the default value 0x0.
- 2. The SLEEPDEEP bit in the ARM Cortex-M3 SCR register must be set to zero.

UM10524

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

3. Use the ARM Cortex-M3 Wait-For-Interrupt (WFI) instruction.

#### 3.9.3.3 Wake-up from Sleep mode

Sleep mode is exited automatically when an interrupt enabled by the NVIC arrives at the processor or a reset occurs. After wake-up due to an interrupt, the microcontroller returns to its original power configuration defined by the contents of the PDRUNCFG and the SYSAHBCLKDIV registers. If a reset occurs, the microcontroller enters the default configuration in Active mode.

#### 3.9.4 Deep-sleep mode

In Deep-sleep mode, the system clock to the processor is disabled as in Sleep mode. All analog blocks are powered down, except for the BOD circuit and the watchdog oscillator, which must be selected or deselected during Deep-sleep mode in the PDSLEEPCFG register. The main clock, and therefore all peripheral clocks, are disabled except for the clock to the watchdog timer if the watchdog oscillator is selected. The IRC is running, but its output is disabled. The flash is in stand-by mode.

**Remark:** If the LOCK bit is set in the WWDT MOD register (<u>Table 269</u>) and the IRC is selected as a clock source for the WWDT, the IRC continues to clock the WWDT in Deep-sleep mode.

Deep-sleep mode eliminates all power used by analog peripherals and all dynamic power used by the processor itself, memory systems and related controllers, and internal buses. The processor state and registers, peripheral registers, and internal SRAM values are maintained, and the logic levels of the pins remain static.

#### 3.9.4.1 Power configuration in Deep-sleep mode

Power consumption in Deep-sleep mode is determined by the Deep-sleep power configuration setting in the PDSLEEPCFG (Table 40) register:

- The watchdog oscillator can be left running in Deep-sleep mode if required for the WWDT.
- If the IRC is locked as the WWDT clock source (see <u>Section 15.7</u>), the IRC continues to run and clock the WWDT in Deep-sleep mode independently of the setting in the PDSLEEPCFG register.
- The BOD circuit can be left running in Deep-sleep mode if required by the application.

#### 3.9.4.2 Programming Deep-sleep mode

The following steps must be performed to enter Deep-sleep mode:

- 1. The PD bits in the PCON register must be set to 0x1 (Table 48).
- 2. Select the power configuration in Deep-sleep mode in the PDSLEEPCFG (Table 40) register.
- 3. Determine if the WWDT clock source must be locked to override the power configuration if the IRC is selected (see <u>Section 15.7</u>).
- 4. If the watchdog oscillator is shut down, ensure that the IRC is powered in the PDRUNCFG register and switch the clock source to IRC in the MAINCLKSEL register (Table 17). This ensures that the system clock is shut down glitch-free.

UM10524

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

- 5. Select the power configuration after wake-up in the PDAWAKECFG (<u>Table 41</u>) register.
- 6. If any of the available wake-up interrupts are needed for wake-up, enable the interrupts in the interrupt wake-up registers (Table 38, Table 39) and in the NVIC.
- 7. Write one to the SLEEPDEEP bit in the ARM Cortex-M3 SCR register.
- 8. Use the ARM WFI instruction.

#### 3.9.4.3 Wake-up from Deep-sleep mode

The microcontroller can wake up from Deep-sleep mode in the following ways:

- Signal on one of the eight pin interrupts selected in <u>Table 35</u>. Each pin interrupt must also be enabled in the STARTERPO register (<u>Table 38</u>) and in the NVIC.
- BOD signal, if the BOD is enabled in the PDSLEEPCFG register:
  - BOD interrupt using the deep-sleep interrupt wake-up register 1 (<u>Table 39</u>). The BOD interrupt must be enabled in the NVIC. The BOD interrupt must be selected in the BODCTRL register.
  - Reset from the BOD circuit. In this case, the BOD circuit must be enabled in the PDSLEEPCFG register, and the BOD reset must be enabled in the BODCTRL register (<u>Table 31</u>).
- WWDT signal, if the watchdog oscillator is enabled in the PDSLEEPCFG register:
  - WWDT interrupt using the interrupt wake-up register 1 (<u>Table 39</u>). The WWDT interrupt must be enabled in the NVIC. The WWDT interrupt must be set in the WWDT MOD register.
  - Reset from the watchdog timer. The WWDT reset must be set in the WWDT MOD
    register. In this case, the watchdog oscillator must be running in Deep-sleep mode
    (see PDSLEEPCFG register), and the WDT must be enabled in the
    SYSAHBCLKCTRL register.
- USB wake-up signal using the interrupt wake-up register 1 (<u>Table 39</u>). For details, see <u>Section 10.7.6</u>.
- GPIO group interrupt signal (see <u>Table 39</u>).

**Remark:** If the watchdog oscillator is running in Deep-sleep mode, its frequency determines the wake-up time.

#### 3.9.5 Power-down mode

In Power-down mode, the system clock to the processor is disabled as in Sleep mode. All analog blocks are powered down, except for the BOD circuit and the watchdog oscillator, which must be selected or deselected during Power-down mode in the PDSLEEPCFG register. The main clock and therefore all peripheral clocks are disabled except for the clock to the watchdog timer if the watchdog oscillator is selected. The IRC itself and the flash are powered down, decreasing power consumption compared to Deep-sleep mode.

**Remark:** Do not set the LOCK bit in the WWDT MOD register (<u>Table 269</u>) when the IRC is selected as a clock source for the WWDT. This prevents the part from entering the Power-down mode correctly.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Power-down mode eliminates all power used by analog peripherals and all dynamic power used by the processor itself, memory systems and related controllers, and internal buses. The processor state and registers, peripheral registers, and internal SRAM values are maintained, and the logic levels of the pins remain static. Wake-up times are longer compared to the Deep-sleep mode.

#### 3.9.5.1 Power configuration in Power-down mode

Power consumption in Power-down mode can be configured by the power configuration setting in the PDSLEEPCFG (<u>Table 40</u>) register in the same way as for Deep-sleep mode (see <u>Section 3.9.4.1</u>):

- The watchdog oscillator can be left running in Deep-sleep mode if required for the WWDT.
- The BOD circuit can be left running in Deep-sleep mode if required by the application.

#### 3.9.5.2 Programming Power-down mode

The following steps must be performed to enter Power-down mode:

- 1. The PD bits in the PCON register must be set to 0x2 (Table 48).
- 2. Select the power configuration in Power-down mode in the PDSLEEPCFG (Table 40) register.
- 3. If the lock bit 5 in the WWDT MOD register is set (<u>Table 269</u>) and the IRC is selected as the WWDT clock source, reset the part to clear the lock bit and then select the watchdog oscillator as the WWDT clock source.
- 4. If the watchdog oscillator is shut down, ensure that the IRC is powered in the PDRUNCFG register and switch the clock source to IRC in the MAINCLKSEL register (Table 17). This ensures that the system clock is shut down glitch-free.
- 5. Select the power configuration after wake-up in the PDAWAKECFG (<u>Table 41</u>) register.
- 6. If any of the available wake-up interrupts are used for wake-up, enable the interrupts in the interrupt wake-up registers (Table 38, Table 39) and in the NVIC.
- 7. Write one to the SLEEPDEEP bit in the ARM Cortex-M3 SCR register.
- 8. Use the ARM WFI instruction.

#### 3.9.5.3 Wake-up from Power-down mode

The microcontroller can wake up from Power-down mode in the same way as from Deep-sleep mode:

- Signal on one of the eight pin interrupts selected in <u>Table 35</u>. Each pin interrupt must also be enabled in the STARTERP0 register (<u>Table 38</u>) and in the NVIC.
- BOD signal, if the BOD is enabled in the PDSLEEPCFG register:
  - BOD interrupt using the interrupt wake-up register 1 (<u>Table 39</u>). The BOD interrupt must be enabled in the NVIC. The BOD interrupt must be selected in the BODCTRL register.
  - Reset from the BOD circuit. In this case, the BOD reset must be enabled in the BODCTRL register (Table 31).
- WWDT signal, if the watchdog oscillator is enabled in the PDSLEEPCFG register:

UM10524

40 of 416

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

- WWDT interrupt using the interrupt wake-up register 1 (<u>Table 39</u>). The WWDT interrupt must be enabled in the NVIC. The WWDT interrupt must be set in the WWDT MOD register.
- Reset from the watchdog timer. The WWDT reset must be set in the WWDT MOD register.
- USB wake-up signal interrupt wake-up register 1 (<u>Table 41</u>). For details, see Section 10.7.6.
- GPIO group interrupt signal (see Table 39).

#### 3.9.6 Deep power-down mode

In Deep power-down mode, power and clocks are shut off to the entire chip with the exception of the WAKEUP pin. The Deep power-down mode is controlled by the PMU (see <u>Chapter 4</u>).

During Deep power-down mode, the contents of the SRAM and registers are not retained except for a small amount of data which can be stored in the general purpose registers of the PMU block.

All functional pins are tri-stated in Deep power-down mode except for the WAKEUP pin.

**Remark:** Setting bit 3 in the PCON register (<u>Section 4.3.1</u>) prevents the part from entering Deep-power down mode.

#### 3.9.6.1 Power configuration in Deep power-down mode

Deep power-down mode has no configuration options. All clocks, the core, and all peripherals are powered down. Only the WAKEUP pin is powered.

#### 3.9.6.2 Programming Deep power-down mode

The following steps must be performed to enter Deep power-down mode:

- 1. Pull the WAKEUP pin externally HIGH.
- 2. Ensure that bit 3 in the PCON register (Table 48) is cleared.
- 3. Write 0x3 to the PD bits in the PCON register (see Table 48).
- 4. Store data to be retained in the general purpose registers (Section 4.3.2).
- 5. Write one to the SLEEPDEEP bit in the ARM Cortex-M3 SCR register.
- 6. Use the ARM WFI instruction.

#### 3.9.6.3 Wake-up from Deep power-down mode

Pulling the WAKEUP pin LOW wakes up the LPC1315/16/17/45/46/47 from Deep power-down, and the chip goes through the entire reset process (Section 3.6).

- 1. On the WAKEUP pin, transition from HIGH to LOW.
  - The PMU will turn on the on-chip voltage regulator. When the core voltage reaches
    the power-on-reset (POR) trip point, a system reset will be triggered and the chip
    re-boots.
  - All registers except the GPREG0 to GPREG4 will be in their reset state.

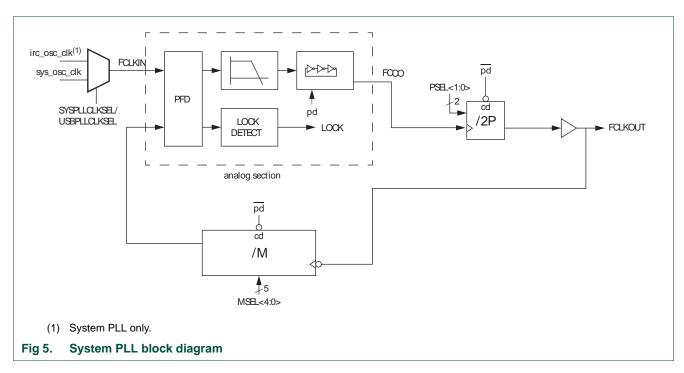

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

- Once the chip has booted, read the deep power-down flag in the PCON register (<u>Table 48</u>) to verify that the reset was caused by a wake-up event from Deep power-down and was not a cold reset.
- 3. Clear the deep power-down flag in the PCON register (Table 48).
- 4. (Optional) Read the stored data in the general purpose registers (Section 4.3.2).
- 5. Set up the PMU for the next Deep power-down cycle.

**Remark:** The RESET pin has no functionality in Deep power-down mode.

### 3.10 System PLL/USB PLL functional description

The LPC1315/16/17/45/46/47 uses the system PLL to create the clocks for the core and peripherals. An identical PLL is available for the USB.

The block diagram of this PLL is shown in Figure 5. The input frequency range is 10 MHz to 25 MHz. The input clock is fed directly to the Phase-Frequency Detector (PFD). This block compares the phase and frequency of its inputs, and generates a control signal when phase and/ or frequency do not match. The loop filter filters these control signals and drives the current controlled oscillator (CCO), which generates the main clock and optionally two additional phases. The CCO frequency range is 156 MHz to 320 MHz. These clocks are either divided by 2×P by the programmable post divider to create the output clocks, or are sent directly to the outputs. The main output clock is then divided by M by the programmable feedback divider to generate the feedback clock. The output signal of the phase-frequency detector is also monitored by the lock detector, to signal when the PLL has locked on to the input clock.

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

#### 3.10.1 Lock detector

The lock detector measures the phase difference between the rising edges of the input and feedback clocks. Only when this difference is smaller than the so called "lock criterion" for more than eight consecutive input clock periods, the lock output switches from low to high. A single too large phase difference immediately resets the counter and causes the lock signal to drop (if it was high). Requiring eight phase measurements in a row to be below a certain figure ensures that the lock detector will not indicate lock until both the phase and frequency of the input and feedback clocks are very well aligned. This effectively prevents false lock indications, and thus ensures a glitch free lock signal.

#### 3.10.2 Power-down control

To reduce the power consumption when the PLL clock is not needed, a Power-down mode has been incorporated. This mode is enabled by setting the SYSPLL\_PD bit to one in the Power-down configuration register (Table 42). In this mode, the internal current reference will be turned off, the oscillator and the phase-frequency detector will be stopped and the dividers will enter a reset state. While in Power-down mode, the lock output will be low to indicate that the PLL is not in lock. When the Power-down mode is terminated by setting the SYSPLL\_PD bit to zero, the PLL will resume its normal operation and will make the lock signal high once it has regained lock on the input clock.

#### 3.10.3 Divider ratio programming

#### Post divider

The division ratio of the post divider is controlled by the PSEL bits. The division ratio is two times the value of P selected by PSEL bits as shown in <u>Table 8</u> and <u>Table 10</u>. This guarantees an output clock with a 50% duty cycle.

#### Feedback divider

The feedback divider's division ratio is controlled by the MSEL bits. The division ratio between the PLL's output clock and the input clock is the decimal value on MSEL bits plus one, as specified in Table 8 and Table 10.

#### Changing the divider values

Changing the divider ratio while the PLL is running is not recommended. As there is no way to synchronize the change of the MSEL and PSEL values with the dividers, the risk exists that the counter will read in an undefined value, which could lead to unwanted spikes or drops in the frequency of the output clock. The recommended way of changing between divider settings is to power down the PLL, adjust the divider settings and then let the PLL start up again.

#### 3.10.4 Frequency selection

The PLL frequency equations use the following parameters (also see Figure 3):

#### Chapter 3: LPC1315/16/17/45/46/47 System control block

Table 45. PLL frequency parameters

Parameter	System PLL
FCLKIN	Frequency of sys_pllclkin (input clock to the system PLL) from the PLL clock multiplexer (see <u>Table 15</u> and <u>Table 16</u> ).
FCCO	Frequency of the Current Controlled Oscillator (CCO); 156 to 320 MHz.
FCLKOUT	Frequency of sys_pllclkout
Р	System PLL post divider ratio; PSEL bits in PLL control registers (see $\underline{\text{Table 8}}$ and $\underline{\text{Table 10}}$ ).
M	System PLL feedback divider register; MSEL bits in the PLL control registers (see <u>Table 8</u> and <u>Table 10</u> ).

#### 3.10.4.1 Normal mode

In this mode the post divider is enabled, giving a 50% duty cycle clock with the following frequency relations:

(1)

$$Fclkout = M \times Fclkin = (FCCO)/(2 \times P)$$

To select the appropriate values for M and P, it is recommended to follow these steps:

- 1. Specify the input clock frequency Fclkin.
- 2. Calculate M to obtain the desired output frequency Fclkout with  $M = F_{clkout} / F_{clkin}$ .
- 3. Find a value so that FCCO =  $2 \times P \times F_{clkout}$ .
- 4. Verify that all frequencies and divider values conform to the limits specified in <u>Table 8</u> and <u>Table 10</u>.

<u>Table 46</u> shows how to configure the PLL for a 12 MHz crystal oscillator using the SYSPLLCTRL register (<u>Table 8</u>). The main clock is equivalent to the system clock if the system clock divider SYSAHBCLKDIV is set to one (see <u>Table 19</u>).

Table 46. PLL configuration examples

PLL input clock sys_pllclkin (Fclkin)	Main clock (Fclkout)	MSEL bits Table 8	M divider value	PSEL bits Table 8	P divider value	FCCO frequency
12 MHz	48 MHz	00011(binary)	4	01 (binary)	2	192 MHz
12 MHz	36 MHz	00010(binary)	3	10 (binary)	4	288 MHz
12 MHz	24 MHz	00001(binary)	2	10 (binary)	4	192 MHz

#### 3.10.4.2 Power-down mode

In this mode, the internal current reference will be turned off, the oscillator and the phase-frequency detector will be stopped and the dividers will enter a reset state. While in Power-down mode, the lock output will be low, to indicate that the PLL is not in lock. When the Power-down mode is terminated by SYSPLL\_PD bit to zero in the Power-down configuration register (Table 42), the PLL will resume its normal operation and will make the lock signal high once it has regained lock on the input clock.

# Chapter 4: LPC1315/16/17/45/46/47 Power Management Unit (PMU)

Rev. 4 — 12 March 2013

**User manual** 

## 4.1 How to read this chapter

The PMU is identical on all LPC1315/16/17/45/46/47 parts. Also refer to Chapter 5 for power control.

#### 4.2 Introduction

The PMU controls the Deep power-down mode. Four general purpose register in the PMU can be used to retain data during Deep power-down mode.

## 4.3 Register description

Table 47. Register overview: PMU (base address 0x4003 8000)

Name	Access	Address offset	Description	Reset value	Reference
PCON	R/W	0x000	Power control register	0x0	Table 48
GPREG0	R/W	0x004	General purpose register 0	0x0	Table 49
GPREG1	R/W	800x0	General purpose register 1	0x0	Table 49
GPREG2	R/W	0x00C	General purpose register 2	0x0	Table 49
GPREG3	R/W	0x010	General purpose register 3	0x0	Table 49
GPREG4	R/W	0x014	General purpose register 4	0x0	Table 50

#### 4.3.1 Power control register

The power control register selects whether one of the ARM Cortex-M3 controlled power-down modes (Sleep mode or Deep-sleep/Power-down mode) or the Deep power-down mode is entered and provides the flags for Sleep or Deep-sleep/Power-down modes and Deep power-down modes respectively. See <a href="Section 3.9">Section 3.9</a> for details on how to enter the power-down modes.

Table 48. Power control register (PCON, address 0x4003 8000) bit description

Bit	Symbol	Value	Description	Reset value
2:0 PM		Power mode	000	
		0x0	Default. The part is in active or sleep mode.	
		0x1	ARM WFI will enter Deep-sleep mode.	
		0x2	ARM WFI will enter Power-down mode.	
		0x3	ARM WFI will enter Deep-power down mode (ARM Cortex-M3 core powered-down).	

#### Chapter 4: LPC1315/16/17/45/46/47 Power Management Unit (PMU)

Table 48. Power control register (PCON, address 0x4003 8000) bit description ...continued

Bit	Symbol	Value	Description	Reset value
3	NODPD		A 1 in this bit prevents entry to Deep power-down mode when 0x3 is written to the PM field above, the SLEEPDEEP bit is set, and a WFI is executed. This bit is cleared only by power-on reset, so writing a one to this bit locks the part in a mode in which Deep power-down mode is blocked.	0
7:4	-	-	Reserved. Do not write ones to this bit.	0
8	SLEEPFLAG		Sleep mode flag	0
		0	Read: No power-down mode entered. LPC1315/16/17/45/46/47 is in Active mode. Write: No effect.	
		1	Read: Sleep/Deep-sleep or Deep power-down mode entered. Write: Writing a 1 clears the SLEEPFLAG bit to 0.	
10:9	-	-	Reserved. Do not write ones to this bit.	0
11	DPDFLAG		Deep power-down flag	0
	1	Read: Deep power-down mode <b>not</b> entered. Write: No effect.	0	
		1	Read: Deep power-down mode entered. Write: Clear the Deep power-down flag.	
31:12	-	-	Reserved. Do not write ones to this bit.	0

#### 4.3.2 General purpose registers 0 to 3

The general purpose registers retain data through the Deep power-down mode when power is still applied to the  $V_{DD}$  pin but the chip has entered Deep power-down mode. Only a "cold" boot when all power has been completely removed from the chip will reset the general purpose registers.

Table 49. General purpose registers 0 to 3 (GPREG0 - GPREG3, address 0x4003 8004 to 0x4003 8010) bit description

Bit	Symbol	Description	Reset value
31:0	GPDATA	Data retained during Deep power-down mode.	0x0

#### 4.3.3 General purpose register 4

The general purpose register 4 retains data through the Deep power-down mode when power is still applied to the  $V_{DD}$  pin but the chip has entered Deep power-down mode. Only a "cold" boot, when all power has been completely removed from the chip, will reset the general purpose registers.

**Remark:** If there is a possibility that the external voltage applied on pin  $V_{DD}$  drops below 2.2 V during Deep power-down, the hysteresis of the WAKEUP input pin has to be disabled in this register before entering Deep power-down mode in order for the chip to wake up.

#### Chapter 4: LPC1315/16/17/45/46/47 Power Management Unit (PMU)

Table 50. General purpose register 4 (GPREG4, address 0x4003 8014) bit description

Bit	Symbol	Value	Description	Reset value
9:0	-	-	Reserved. Do not write ones to this bit.	0x0
10 WAKEUPHYS 0			WAKEUP pin hysteresis enable	0x0
		0	Hysteresis for WAKUP pin disabled.	
		1	Hysteresis for WAKEUP pin enabled.	
31:11	GPDATA		Data retained during Deep power-down mode.	0x0

## 4.4 Functional description

For details of entering and exiting reduced power modes, see Section 3.9.

## UM10524

## Chapter 5: LPC1315/16/17/45/46/47 Power profiles

Rev. 4 — 12 March 2013

**User manual** 

## 5.1 How to read this chapter

The power profiles are available for all LPC1315/16/17/45/46/47.

#### 5.2 Features

- Includes ROM-based application services
- Power Management services
- Clocking services

## 5.3 General description

The power consumption in Active and Sleep modes can be optimized for the application through simple calls to the power profile. The power configuration routine configures the LPC1315/16/17/45/46/47 for one of the following power modes:

- Default mode corresponding to power configuration after reset.
- CPU performance mode corresponding to optimized processing capability.
- Efficiency mode corresponding to optimized balance of current consumption and CPU performance.
- Low-current mode corresponding to lowest power consumption.

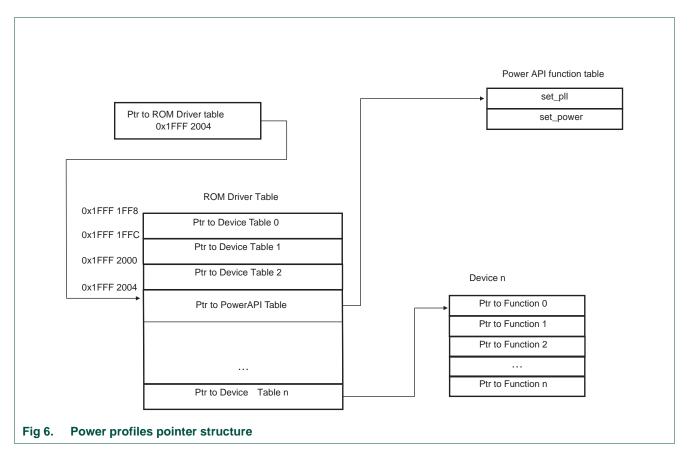

In addition, the power profile includes routines to select the optimal PLL settings for a given system clock and PLL input clock.

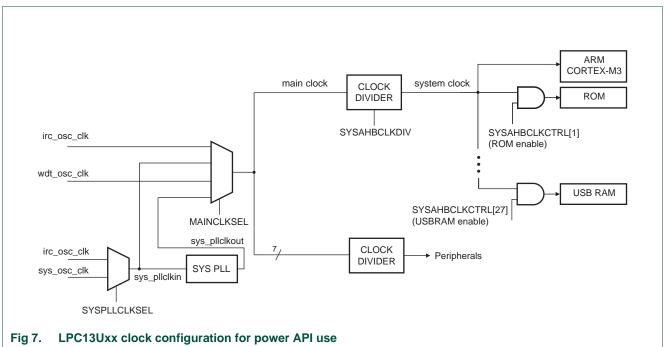

**Remark:** When using the USB, configure the power profiles in Default mode.

**Remark:** Disable all interrupts before making calls to the power profile API. You can re-enable the interrupts after the power profile API calls have completed.

The API calls to the ROM are performed by executing functions which are pointed by a pointer within the ROM Driver Table. Figure 6 shows the pointer structure used to call the Power Profiles API.

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

#### 5.4 Definitions

The following elements have to be defined in an application that uses the power profiles:

```
typedef struct _PWRD {
    void (*set_pll)(unsigned int cmd[], unsigned int resp[]);
    void (*set_power)(unsigned int cmd[], unsigned int resp[]);
} PWRD;
typedef struct _ROM {
    const PWRD * pWRD;
} ROM;
ROM ** rom = (ROM **) 0x1FFF1FF8;
unsigned int command[4], result[2];
```

### 5.5 Clocking routine

#### 5.5.1 set\_pll

This routine sets up the system PLL according to the calling arguments. If the expected clock can be obtained by simply dividing the system PLL input,  $set\_pll$  bypasses the PLL to lower system power consumption.

**IMPORTANT:** Before this routine is invoked, the PLL clock source (IRC/system oscillator) must be selected (<u>Table 15</u>), the main clock source must be set to the input clock to the system PLL (<u>Table 17</u>) and the system AHB clock divider must be set to 1 (<u>Table 18</u>).

set\_pll attempts to find a PLL setup that matches the calling parameters. Once a combination of a feedback divider value (SYSPLLCTRL, M), a post divider ratio (SYSPLLCTRL, P) and the system/AHB clock divider (SYSAHBCLKDIV) is found, set\_pll applies the selected values and switches the main clock source selection to the system PLL clock out (if necessary).

The routine returns a result code that indicates if the system PLL was successfully set (PLL\_CMD\_SUCCESS) or not (in which case the result code identifies what went wrong). The current system frequency value is also returned. The application should use this information to adjust other clocks in the device (the SSP, UART, and USB clocks, and/or clockout).

Table 51. set\_pll routine

Routine	set_pll			
Input	Param0: system PLL input frequency (in kHz)			
	Param1: expected system clock (in kHz)			
	Param2: mode (CPU_FREQ_EQU, CPU_FREQ_LTE, CPU_FREQ_GTE, CPU_FREQ_APPROX)			
	Param3: system PLL lock timeout			
Result	Result0: PLL_CMD_SUCCESS   PLL_INVALID_FREQ   PLL_INVALID_MODE   PLL_FREQ_NOT_FOUND   PLL_NOT_LOCKED			
	Result1: system clock (in kHz)			

The following definitions are needed when making set\_pll power routine calls:

```
/* set_pll mode options */
```

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

```
#define
        CPU FREQ EQU
                              0
#define CPU_FREQ_LTE
                              1
#define CPU_FREQ_GTE
                              2
#define CPU_FREQ_APPROX
                              3
/* set_pll result0 options */
#define PLL_CMD_SUCCESS
                              0
#define PLL INVALID FREQ
                              1
#define PLL_INVALID_MODE
                              2
#define PLL FREQ NOT FOUND
                              3
#define
         PLL NOT LOCKED
                              4
```

#### 5.5.1.1 System PLL input frequency and expected system clock

set\_pll looks for a setup in which the system PLL clock does not exceed 50 MHz. It easily finds a solution when the ratio between the expected system clock and the system PLL input frequency is an integer value, but it can also find solutions in other cases.

The system PLL input frequency (*Param0*) must be between 10000 to 25000 kHz (10 MHz to 25 MHz) inclusive. The expected system clock (*Param1*) must be between 1 and 50000 kHz inclusive. If either of these requirements is not met, *set\_pll* returns PLL\_INVALID\_FREQ and returns *Param0* as *Result1* since the PLL setting is unchanged.

#### 5.5.1.2 Mode

The first priority of set\_pll is to find a setup that generates the system clock at exactly the rate specified in Param1. If it is unlikely that an exact match can be found, input parameter mode (Param2) should be used to specify if the actual system clock can be less than or equal, greater than or equal or approximately the value specified as the expected system clock (Param1).

A call specifying CPU\_FREQ\_EQU will only succeed if the PLL can output exactly the frequency requested in *Param1*.

CPU\_FREQ\_LTE can be used if the requested frequency should not be exceeded (such as overall current consumption and/or power budget reasons).

CPU\_FREQ\_GTE helps applications that need a minimum level of CPU processing capabilities.

CPU\_FREQ\_APPROX results in a system clock that is as close as possible to the requested value (it may be greater than or less than the requested value).

If an illegal mode is specified,  $set_pll$  returns PLL\_INVALID\_MODE. If the expected system clock is out of the range supported by this routine,  $set_pll$  returns PLL\_FREQ\_NOT\_FOUND. In these cases the current PLL setting is not changed and Param0 is returned as Result1.

#### 5.5.1.3 System PLL lock time-out

It should take no more than 100  $\mu$ s for the system PLL to lock if a valid configuration is selected. If *Param3* is zero,  $set\_pll$  will wait indefinitely for the PLL to lock. If a non-zero value is provided, that is how many times the code will check for a successful PLL lock event before it returns PLL\_NOT\_LOCKED. In this case the PLL settings are unchanged and Param0 is returned as Result1.

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

**Hint:** setting *Param3* equal to the system PLL frequency [Hz] divided by 10000 will provide more than enough PLL lock-polling cycles.

#### 5.5.1.4 Code examples

The following examples illustrate some of the features of set pll discussed above.

#### 5.5.1.4.1 Invalid frequency (device maximum clock rate exceeded)

```
command[0] = 12000;
command[1] = 60000;
command[2] = CPU_FREQ_EQU;
command[3] = 0;
(*rom)->pWRD->set_pll(command, result);
```

The above code specifies a 12 MHz PLL input clock and a system clock of exactly 60 MHz. The application was ready to infinitely wait for the PLL to lock. But the expected system clock of 60 MHz exceeds the maximum of 50 MHz. Therefore  $set\_pll$  returns PLL\_INVALID\_FREQ in result[0] and 12000 in result[1] without changing the PLL settings.

#### 5.5.1.4.2 Invalid frequency selection (system clock divider restrictions)

```
command[0] = 12000;
command[1] = 40;
command[2] = CPU_FREQ_LTE;
command[3] = 0;
(*rom)->pWRD->set_pll(command, result);
```

The above code specifies a 12 MHz PLL input clock, a system clock of no more than 40 kHz and no time-out while waiting for the PLL to lock. Since the maximum divider value for the system clock is 255 and running at 40 kHz would need a divide by value of 300,  $set\_pll$  returns PLL\_INVALID\_FREQ in result[0] and 12000 in result[1] without changing the PLL settings.

#### 5.5.1.4.3 Exact solution cannot be found (PLL)

```
command[0] = 12000;
command[1] = 25000;
command[2] = CPU_FREQ_EQU;
command[3] = 0;
(*rom)->pWRD->set pl1(command, result);
```

The above code specifies a 12 MHz PLL input clock and a system clock of exactly 25 MHz. The application was ready to infinitely wait for the PLL to lock. Since there is no valid PLL setup within earlier mentioned restrictions,  $set\_pll$  returns PLL\_FREQ\_NOT\_FOUND in result[0] and 12000 in result[1] without changing the PLL settings.

#### 5.5.1.4.4 System clock less than or equal to the expected value

```
command[0] = 12000;
command[1] = 25000;
command[2] = CPU_FREQ_LTE;
command[3] = 0;
(*rom)->pWRD->set_pll(command, result);
```

UM10524

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

The above code specifies a 12 MHz PLL input clock, a system clock of no more than 25 MHz and no locking time-out.  $set\_pll$  returns PLL\_CMD\_SUCCESS in result[0] and 24000 in result[1]. The new system clock is 24 MHz.

#### 5.5.1.4.5 System clock greater than or equal to the expected value

```
command[0] = 12000;
command[1] = 25000;
command[2] = CPU_FREQ_GTE;
command[3] = 0;
(*rom)->pWRD->set pll(command, result);
```

The above code specifies a 12 MHz PLL input clock, a system clock of at least 25 MHz and no locking time-out. set\_pll returns PLL\_CMD\_SUCCESS in result[0] and 36000 in result[1]. The new system clock is 36 MHz.

#### 5.5.1.4.6 System clock approximately equal to the expected value

```
command[0] = 12000;
command[1] = 16500;
command[2] = CPU_FREQ_APPROX;
command[3] = 0;
(*rom)->pWRD->set_pll(command, result);
```

The above code specifies a 12 MHz PLL input clock, a system clock of approximately 16.5 MHz and no locking time-out. *set\_pll* returns PLL\_CMD\_SUCCESS in *result[0]* and 16000 in *result[1]*. The new system clock is 16 MHz.

#### 5.6 Power routine

#### 5.6.1 set\_power

This routine configures the device's internal power control settings according to the calling arguments. The goal is to reduce active power consumption while maintaining the feature of interest to the application close to its optimum.

set\_power returns a result code that reports if the power setting was successfully changed or not.

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

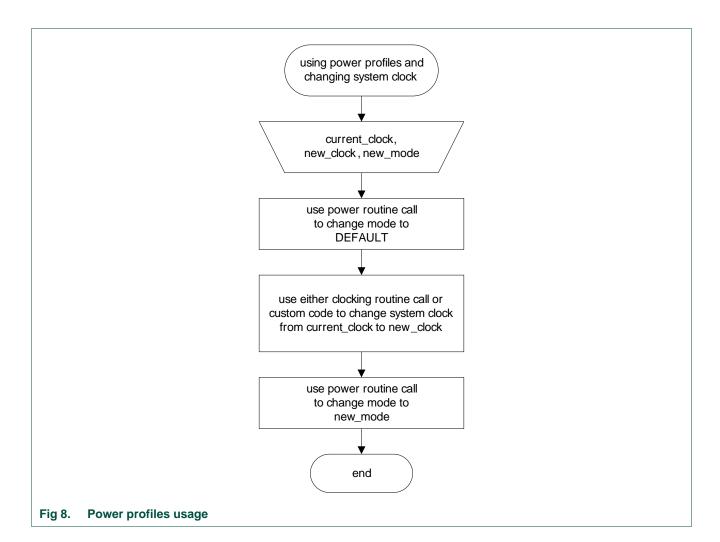

Table 52. set\_power routine

Routine	set_power				
Input	Param0: new system clock (in MHz)				
	Param1: mode (PWR_DEFAULT, PWR_CPU_PERFORMANCE, PWR_EFFICIENCY, PWR_LOW_CURRENT)				
	Param2: current system clock (in MHz)				
Result	Result0: PWR_CMD_SUCCESS   PWR_INVALID_FREQ   PWR_INVALID_MODE				

#### The following definitions are needed for set\_power routine calls:

```
/* set_power mode options */
#define
        PWR_DEFAULT
                               0
#define
          PWR_CPU_PERFORMANCE
                               1
#define PWR EFFICIENCY
                               2
#define PWR_LOW_CURRENT
                               3
/* set_power result0 options */
#define
        PWR CMD SUCCESS
#define
          PWR_INVALID_FREQ
                               1
#define
                               2
          PWR_INVALID_MODE
```

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

#### 5.6.1.1 New system clock

The new system clock is the clock rate at which the microcontroller will be running after either a successful execution of a clocking routine call or a similar code provided by the user. This operand must be an integer between 1 to 50 MHz inclusive. If a value out of this range is supplied, <code>set\_power</code> returns PWR\_INVALID\_FREQ and does not change the power control system.

#### 5.6.1.2 Mode

The input parameter mode (*Param1*) specifies one of four available power settings. If an illegal selection is provided, *set\_power* returns PWR\_INVALID\_MODE and does not change the power control system.

PWR\_DEFAULT keeps the device in a baseline power setting similar to its reset state.

PWR\_CPU\_PERFORMANCE configures the microcontroller so that it can provide more processing capability to the application. CPU performance is 30% better than the default option.

PWR\_EFFICIENCY setting was designed to find a balance between active current and the CPU's ability to execute code and process data. In this mode the device outperforms the default mode both in terms of providing higher CPU performance and lowering active current.

PWR\_LOW\_CURRENT is intended for those solutions that focus on lowering power consumption rather than CPU performance.

#### 5.6.1.3 Current system clock

The current system clock is the clock rate at which the microcontroller is running when  $set\_power$  is called. This parameter is an integer between from 1 and 50 MHz inclusive.

#### 5.6.1.4 Code examples

The following examples illustrate some of the set power features discussed above.

#### 5.6.1.4.1 Invalid frequency (device maximum clock rate exceeded)

```
command[0] = 55;
command[1] = PWR_CPU_PERFORMANCE;
command[2] = 12;
(*rom)->pWRD->set power(command, result);
```

The above setup would be used in a system running at 12 MHz attempting to switch to 55 MHz system clock, with a need for maximum CPU processing power. Since the specified 55 MHz clock is above the 50 MHz maximum,  $set\_power$  returns PWR\_INVALID\_FREQ in result[0] without changing anything in the existing power setup.

#### 5.6.1.4.2 An applicable power setup

```
command[0] = 24;
command[1] = PWR_CPU_EFFICIENCY;
command[2] = 12;
(*rom)->pWRD->set_power(command, result);
```

#### Chapter 5: LPC1315/16/17/45/46/47 Power profiles

The above code specifies that an application running at a system clock of 12 MHz will switch to 24 MHz with emphasis on efficiency. set\_power returns PWR\_CMD\_SUCCESS in result[0] after configuring the microcontroller's internal power control features.

## 6.1 How to read this chapter

The USB related interrupts #22, 23, and 30 are only available on LPC134x parts.

#### 6.2 Introduction

The Nested Vectored Interrupt Controller (NVIC) is an integral part of the Cortex-M3. The tight coupling to the CPU allows for low interrupt latency and efficient processing of late arriving interrupts.

#### 6.3 Features

- Nested Vectored Interrupt Controller that is an integral part of the ARM Cortex-M3
- Tightly coupled interrupt controller provides low interrupt latency
- Controls system exceptions and peripheral interrupts
- The NVIC supports 32 vectored interrupts
- 8 programmable interrupt priority levels with hardware priority level masking
- Software interrupt generation
- Support for NMI

## 6.4 Interrupt sources

Table 53 lists the interrupt sources for each peripheral function. Each peripheral device may have one or more interrupt lines to the Vectored Interrupt Controller. Each line may represent more than one interrupt source. There is no significance or priority about what line is connected where, except for certain standards from ARM.

See Section 21.5.2 for the NVIC register bit descriptions.

Table 53. Connection of interrupt sources to the Vectored Interrupt Controller

Interrupt number	Name	Description	Flag(s)
0	PIN_INT0	GPIO pin interrupt 0	-
1	PIN_INT1	GPIO pin interrupt 1	-
2	PIN_INT2	GPIO pin interrupt 2	-
3	PIN_INT3	GPIO pin interrupt 3	-
4	PIN_INT4	GPIO pin interrupt 4	-

## 7.1 How to read this chapter

The IOCON register map depends on the package type (see <u>Table 54</u>). Registers for pins that are not available are reserved.

Table 54. IOCON registers available

Package	Port 0	Port 1
LQFP64	PIO0_0 to PIO0_23	PIO1_0 to PIO1_5; PIO1_7 to PIO1_8; PIO1_10 to PIO1_29
LQFP48	PIO0_0 to PIO0_23	PIO1_13 to PIO1_16; PIO1_19 to PIO1_23 to PIO1_29; PIO1_31
HVQFN (no USB)	PIO0_0 to PIO0_23	PIO1_15; PIO1_19; PIO1_23 to PIO1_24
HVQFN (USB)	PIO0_0 to PIO0_23	PIO1_15; PIO1_19

#### 7.2 Introduction

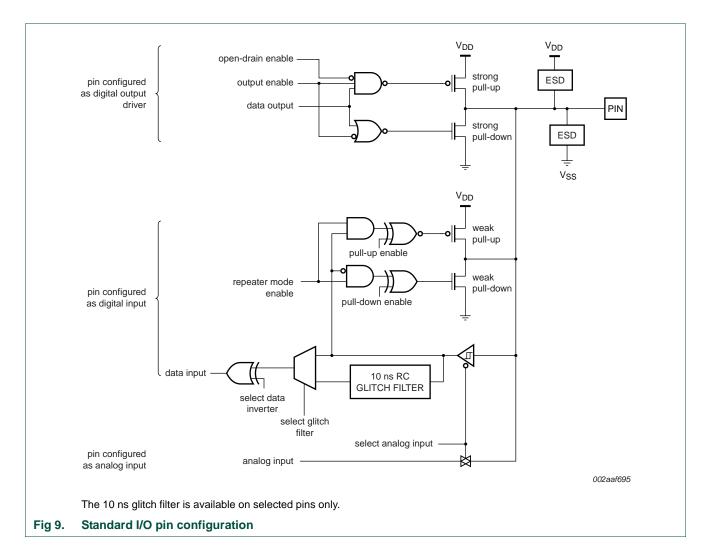

The I/O configuration registers control the electrical characteristics of the pads. The following features are programmable:

- Pin function
- Internal pull-up/pull-down resistor or bus keeper function (repeater mode)
- Open-drain mode for standard I/O pins
- Hysteresis
- Input inverter
- · Glitch filter on selected pins
- Analog input or digital mode for pads hosting the ADC inputs
- I<sup>2</sup>C mode for pads hosting the I<sup>2</sup>C-bus function

## 7.3 General description

The IOCON registers control the function (GPIO or peripheral function) and the electrical characteristics of the port pins (see <u>Figure 9</u>).

#### Chapter 7: LPC1315/16/17/45/46/47 I/O configuration

#### 7.3.1 Pin function

The FUNC bits in the IOCON registers can be set to GPIO (FUNC = 0) or to a peripheral function. If the pins are GPIO pins, the DIR registers determine whether the pin is configured as an input or output (see Section 9.5.3.3). For any peripheral function, the pin direction is controlled automatically depending on the pin's functionality. The DIR registers have no effect for peripheral functions.

#### 7.3.2 Pin mode

The MODE bits in the IOCON register allow the selection of on-chip pull-up or pull-down resistors for each pin or select the repeater mode.

The possible on-chip resistor configurations are pull-up enabled, pull-down enabled, or no pull-up/pull-down. The default value is pull-up enabled.

The repeater mode enables the pull-up resistor if the pin is at a logic HIGH and enables the pull-down resistor if the pin is at a logic LOW. This causes the pin to retain its last known state if it is configured as an input and is not driven externally. The state retention is

61 of 416

#### Chapter 7: LPC1315/16/17/45/46/47 I/O configuration

not applicable to the Deep power-down mode. Repeater mode may typically be used to prevent a pin from floating (and potentially using significant power if it floats to an indeterminate state) if it is temporarily not driven.

#### 7.3.3 Hysteresis

The input buffer for digital functions can be configured with hysteresis or as plain buffer through the IOCON registers.

If the external pad supply voltage  $V_{DD}$  is between 2.5 V and 3.6 V, the hysteresis buffer can be enabled or disabled. If  $V_{DD}$  is below 2.5 V, the hysteresis buffer must be **disabled** to use the pin in input mode.

#### 7.3.4 Input inverter

If the input inverter is enabled, a HIGH pin level is inverted to 0 and a LOW pin level is inverted to 1.

#### 7.3.5 Input glitch filter

Selected pins (pins PIO0\_22, PIO0\_23, and PIO0\_11 to PIO0\_16) provide the option of turning on or off a 10 ns input glitch filter. The glitch filter is turned on by default. The RESET pin has a 20 ns glitch filter (not configurable).

#### 7.3.6 Open-drain mode

A pseudo open-drain mode can be enabled for all digital pins. Note that except for the I<sup>2</sup>C-bus pins, this is not a true open-drain mode.

#### 7.3.7 Analog mode

In analog mode, the digital receiver is disconnected to obtain an accurate input voltage for analog-to-digital conversions. This mode can be selected in those IOCON registers that control pins with an analog function. If analog mode is selected, hysteresis, pin mode, inverter, glitch filter, and open-drain settings have no effect.

For pins without analog functions, the analog mode setting has no effect.

#### 7.3.8 I<sup>2</sup>C mode

If the I<sup>2</sup>C function is selected by the FUNC bits of registers PIO0\_4 (<u>Table 60</u>) and PIO0\_5 (<u>Table 61</u>), then the I<sup>2</sup>C-bus pins can be configured for different I<sup>2</sup>C-modes:

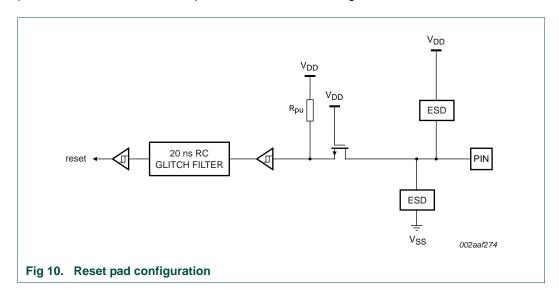

- Standard mode/Fast-mode I<sup>2</sup>C with 50 ns input glitch filter. An open-drain output according to the I<sup>2</sup>C-bus specification can be configured separately.
- Fast-mode Plus I<sup>2</sup>C with 50 ns input glitch filter. In this mode, the pins function as high-current sinks. An open-drain output according to the I<sup>2</sup>C-bus specification can be configured separately.
- Standard functionality without input filter.

**Remark:** Either Standard mode/Fast-mode I<sup>2</sup>C or Standard I/O functionality should be selected if the pin is used as GPIO pin.

#### Chapter 7: LPC1315/16/17/45/46/47 I/O configuration

## 7.3.9 RESET pin (pin RESET\_PIO0\_0)

See <u>Figure 10</u> for the reset pad configuration. RESET functionality is not available in Deep power-down mode. Use the WAKEUP pin to reset the chip and wake up from Deep power-down mode. An external pull-up resistor is required on this pin for the Deep power-down mode. The reset pin includes a fixed 20 ns glitch filter.

#### 7.3.10 WAKEUP pin (pin PIO0\_16)

The WAKEUP pin is combined with pin PIOO\_16 and includes a 20 ns fixed glitch filter. This pin must be pulled HIGH externally to enter Deep power-down mode and pulled LOW to exit Deep power-down mode. A LOW-going pulse as short as 50 ns wakes up the part.

## 7.4.5 I/O configuration for pin PIO0\_4

Table 60. I/O configuration for pin PIO0\_4/SCL (PIO0\_4, address 0x4004 4010) bit description

Bit	Symbol	Value	Description	Reset value
2:0	FUNC		Selects pin function. Values 0x2 to 0x7 are reserved.	0
		0x0	PIO0_4 (open-drain pin).	
		0x1	I2C SCL (open-drain pin).	
7:3	-		Reserved.	

#### Chapter 7: LPC1315/16/17/45/46/47 I/O configuration

Table 60. I/O configuration for pin PIO0\_4/SCL (PIO0\_4, address 0x4004 4010) bit description

Bit	Symbol	Value	Description	Reset value
9:8	I2CMODE		Selects I2C mode (see Section 6.3.8). Select Standard mode (I2CMODE = 0, default) or Standard I/O functionality (I2CMODE = 1) if the pin function is GPIO (FUNC = 0).	0
		0x0	Standard mode/ Fast-mode I2C.	
		0x1	Standard I/O functionality	
		0x2	Fast-mode Plus I2C	
		0x3	Reserved.	
31:10	-		Reserved.	-

### 7.4.6 I/O configuration for pin PIO0\_5

Table 61. I/O configuration for pin PIO0\_5/SDA (PIO0\_5, address 0x4004 4014) bit description

Bit	Symbol	Value	Description	Reset value
2:0	FUNC		Selects pin function. Values 0x2 to 0x7 are reserved.	0
		0x0	PIO0_5 (open-drain pin).	
		0x1	I2C SDA (open-drain pin).	
7:3			Reserved.	
9:8	I2CMODE		Selects I2C mode (see Section 6.3.8). Select Standard mode (I2CMODE = 00, default) or Standard I/O functionality (I2CMODE = 01) if the pin function is GPIO (FUNC = 0).	0
		0x0	Standard mode/ Fast-mode I2C.	
		0x1	Standard I/O functionality	
		0x2	Fast-mode Plus I2C	
		0x3	Reserved.	
31:10	) -		Reserved.	-

## 7.4.7 I/O configuration for pin PIO0\_6

Table 62. I/O configuration for pin PIO0\_6/USB\_CONNECT/SCK0 (PIO0\_6, address 0x4004 4018) bit description

Bit	Symbol	Value	Description	Reset value
2:0	FUNC		Selects pin function. Values 0x3 to 0x7 are reserved.	0
		0x0	PIO0_6.	
		0x1	USB_CONNECT.	
		0x2	SCK0.	

#### Chapter 7: LPC1315/16/17/45/46/47 I/O configuration

Table 62. I/O configuration for pin PIO0\_6/USB\_CONNECT/SCK0 (PIO0\_6, address 0x4004 4018) bit description

<b>D</b> !:	• • •			_	
Bit	Symbol	Value	Description	Reset value	
4:3	4:3	MODE		Selects function mode (on-chip pull-up/pull-down resistor control).	0x2
		0x0	Inactive (no pull-down/pull-up resistor enabled).		
		0x1	Pull-down resistor enabled.		
		0x2	Pull-up resistor enabled.		
		0x3	Repeater mode.

**User manual** 

# 8.1 Pin configuration

### 8.1.1 Pin description

<u>Table 108</u> and <u>Table 109</u> show all pins and their assigned digital or analog functions ordered by GPIO port number. The default function after reset is listed first. All port pins have internal pull-up resistors enabled after reset with the exception of the true open-drain pins PIO0\_4 and PIO0\_5.

Every port pin has a corresponding IOCON register through which the digital or analog function, pull-up/pull-down configuration, repeater, and open-drain modes can be programmed.

To select a port pin for one of the peripheral functions in, program the FUNC bits in the port pin's IOCON register with this function. The user must ensure that the assignment of a function to a port pin is unambiguous for functions that are multiplexed to more than one port pin.

The debug functions for JTAG and SWD are selected by default in their corresponding IOCON registers. All other functions must be programmed in the IOCON block before they can be used.

Table 108. Pin description (LPC1315/16/17 - no USB)

Symbol	LQFP64	LQFP48	HVQFN33		Reset state[1]	Type	Description
RESET/PIO0_0	4	3	2	[2]	I; PU	l	RESET — External reset input with 20 ns glitch filter. A LOW-going pulse as short as 50 ns on this pin resets the device, causing I/O ports and peripherals to take on their default states, and processor execution to begin at address 0. This pin also serves as the debug select input. LOW level selects the JTAG boundary scan. HIGH level selects the ARM SWD debug mode.
					-	I/O	PIO0_0 — General purpose digital input/output pin.
PIO0_1/CLKOUT/ CT32B0_MAT2	<del>_</del>	4	3	[3]	I; PU	I/O	PIO0_1 — General purpose digital input/output pin. A LOW level on this pin during reset starts the ISP command handler.
					-	0	CLKOUT — Clockout pin.
					-	0	CT32B0_MAT2 — Match output 2 for 32-bit timer 0.
PIO0_2/SSEL0/	13	10	8	[3]	I; PU	I/O	PIO0_2 — General purpose digital input/output pin.
CT16B0_CAP0						I/O	SSEL0 — Slave select for SSP0.
						I	CT16B0_CAP0 — Capture input 0 for 16-bit timer 0.
PIO0_3	19	14	9	[3]	I; PU	I/O	PIO0_3 — General purpose digital input/output pin.

### Chapter 8: LPC1315/16/17/45/46/47 Pin configuration

Table 108. Pin description (LPC1315/16/17 - no USB)

Symbol	LQFP64	LQFP48	HVQFN33		Reset state[1]	Туре	Description
PIO0_4/SCL	20	15	10	<u>[4]</u>	IA	I/O	<b>PIOO_4</b> — General purpose digital input/output pin (open-drain).
					-	I/O	<b>SCL</b> — I <sup>2</sup> C-bus clock input/output (open-drain). High-current sink only if I <sup>2</sup> C Fast-mode Plus is selected in the I/O configuration register.
PIO0_5/SDA	21	16	11	<u>[4]</u>	IA	I/O	<b>PIO0_5</b> — General purpose digital input/output pin (open-drain).
					-	I/O	<b>SDA</b> — I <sup>2</sup> C-bus data input/output (open-drain). High-current sink only if I <sup>2</sup> C Fast-mode Plus is selected in the I/O configuration register.
PIO0_6/R/	29	22	15	[3]	I; PU	I/O	PIO0_6 — General purpose digital input/output pin.
SCK0					-	-	R — Reserved.
					-	I/O	SCK0 — Serial clock for SSP0.
PIO0_7/CTS	30	23	16	<u>[5]</u>	I; PU	I/O	<b>PIO0_7</b> — General purpose digital input/output pin (high-current output driver).
					-	I	CTS — Clear To Send input for USART.
PIO0_8/MISO0/	36	27	17	[3]	I; PU	I/O	PIO0_8 — General purpose digital input/output pin.
CT16B0_MAT0					-	I/O	MISO0 — Master In Slave Out for SSP0.
					-	0	CT16B0_MAT0 — Match output 0 for 16-bit timer 0.
PIO0_9/MOSI0/	37	28	18	[3]	I; PU	I/O	PIO0_9 — General purpose digital input/output pin.
CT16B0_MAT1/ SWO					-	I/O	MOSI0 — Master Out Slave In for SSP0.
3440					-	0	CT16B0_MAT1 — Match output 1 for 16-bit timer 0.
					-	0	SWO — Serial wire trace output.
SWCLK/PIO0_10/SCK0/ CT16B0_MAT2	38	29	19	[3]	I; PU	I	<b>SWCLK</b> — Serial wire clock and test clock TCK for JTAG interface.
					-	I/O	PIO0_10 — General purpose digital input/output pin.
					-	0	SCK0 — Serial clock for SSP0.
					-	0	CT16B0_MAT2 — Match output 2 for 16-bit timer 0.
TDI/PIO0_11/AD0/	42	32	21	[6]	I; PU	I	TDI — Test Data In for JTAG interface.
CT32B0_MAT3					-	I/O	PIO0_11 — General purpose digital input/output pin.
					-	I	AD0 — A/D converter, input 0.
					-	0	CT32B0_MAT3 — Match output 3 for 32-bit timer 0.
TMS/PIO0_12/AD1/	44	33	22	[6]	I; PU	I	<b>TMS</b> — Test Mode Select for JTAG interface.
CT32B1_CAP0					-	I/O	PIO_12 — General purpose digital input/output pin.
					-	I	AD1 — A/D converter, input 1.
					-	I	CT32B1_CAP0 — Capture input 0 for 32-bit timer 1.
TDO/PIO0_13/AD2/	45	34	23	[6]	I; PU	0	<b>TDO</b> — Test Data Out for JTAG interface.
CT32B1_MAT0					-	I/O	PIO0_13 — General purpose digital input/output pin.
					-	I	AD2 — A/D converter, input 2.
					-	0	CT32B1_MAT0 — Match output 0 for 32-bit timer 1.

### Chapter 8: LPC1315/16/17/45/46/47 Pin configuration

Table 108. Pin description (LPC1315/16/17 - no USB)

Symbol	LQFP64	LQFP48	HVQFN33		Reset state[1]	Type	Description
TRST/PIO0_14/AD3/	46	35	24	[6]	I; PU	I	TRST — Test Reset for JTAG interface.
CT32B1_MAT1					-	I/O	PIO0_14 — General purpose digital input/output pin.
					-	I	AD3 — A/D converter, input 3.
					-	0	CT32B1_MAT1 — Match output 1 for 32-bit timer 1.
SWDIO/PIO0_15/AD4/	52	39	25	[6]	I; PU	I/O	SWDIO — Serial wire debug input/output.
CT32B1_MAT2					-	I/O	PIO0_15 — General purpose digital input/output pin.
					-	I	AD4 — A/D converter, input 4.
					-	0	CT32B1_MAT2 — Match output 2 for 32-bit timer 1.
PIO0_16/AD5/	53	40	26	<u>[7]</u>	I; PU	I/O	PIO0_16 — General purpose digital input/output pin.
CT32B1_MAT3/WAKEUP					-	I	AD5 — A/D converter, input 5.
					-	0	CT32B1_MAT3 — Match output 3 for 32-bit timer 1.
					-	I	<b>WAKEUP</b> — Deep power-down mode wake-up pin with 20 ns glitch filter. This pin must be pulled HIGH externally to enter Deep power-down mode and pulled LOW to exide Deep power-down mode. A LOW-going pulse as short as 50 ns wakes up the part.
PIO0_17/RTS/	60	45	30	[3]	I; PU	I/O	PIO0_17 — General purpose digital input/output pin.
CT32B0_CAP0/SCLK					-	0	RTS — Request To Send output for USART.
					-	I	CT32B0_CAP0 — Capture input 0 for 32-bit timer 0.
					-	I/O	<b>SCLK</b> — Serial clock input/output for USART in synchronous mode.
PIO0_18/RXD/	61	46	31	[3]	I; PU	I/O	PIO0_18 — General purpose digital input/output pin.
CT32B0_MAT0					-	I	<b>RXD</b> — Receiver input for USART. Used in UART ISP mode.
					-	0	CT32B0_MAT0 — Match output 0 for 32-bit timer 0.
PIO0_19/TXD/	62	47	32	[3]	I; PU	I/O	PIO0_19 — General purpose digital input/output pin.
CT32B0_MAT1					-	0	<b>TXD</b> — Transmitter output for USART. Used in UART IS mode.
					-	0	CT32B0_MAT1 — Match output 1 for 32-bit timer 0.
PIO0_20/CT16B1_CAP0	11	9	7	[3]	I; PU	I/O	PIO0_20 — General purpose digital input/output pin.
					-	I	CT16B1_CAP0 — Capture input 0 for 16-bit timer 1.
PIO0_21/CT16B1_MAT0/	22	17	12	[3]	I; PU	I/O	PIO0_21 — General purpose digital input/output pin.
MOSI1					-	0	CT16B1_MAT0 — Match output 0 for 16-bit timer 1.
					-	I/O	MOSI1 — Master Out Slave In for SSP1.
PIO0_22/AD6/	40	30	20	[6]	I; PU	I/O	PIO0_22 — General purpose digital input/output pin.
CT16B1_MAT1/MISO1					-	I	AD6 — A/D converter, input 6.
					-	0	CT16B1_MAT1 — Match output 1 for 16-bit timer 1.
					-	I/O	MISO1 — Master In Slave Out for SSP1.
PIO0_23/AD7	56	42	27	[6]	I; PU	I/O	PIO0_23 — General purpose digital input/output pin.
					-	ı	AD7 — A/D converter, input 7.

					-	I/O	<b>SCLK</b> — Serial clock input/output for USART in synchronous mode.
PIO1_29/SCK0/	41	31	-	[3]	I; PU	I/O	PIO1_29 — General purpose digital input/output pin.
CT32B0_CAP1					-	I/O	SCK0 — Serial clock for SSP0.
					-	I	CT32B0_CAP1 — Capture input 1 for 32-bit timer 0.
PIO1_31	-	25	-	[3]	I; PU	I/O	PIO1_31 — General purpose digital input/output pin.
n.c.	25	19	-		-	-	Not connected.
n.c.	26	20	-		-	-	Not connected.
XTALIN	8	6	4	[8]	-	-	Input to the oscillator circuit and internal clock generator circuits. Input voltage must not exceed 1.8 V.
XTALOUT	9	7	5	[8]	-	-	Output from the oscillator amplifier.

Table 108. Pin description (LPC1315/16/17 - no USB)

Symbol	LQFP64	LQFP48	HVQFN33	Reset state[1]	Туре	Description
$V_{DDA}$	59	-	-	-	-	analog 3.3 V pad supply voltage: This should be nominally the same voltage as $V_{DD}$ but should be isolated to minimize noise and error. This voltage is used to power the ADC. This pin should be tied to 3.3 V if the ADC is not used.
VREFN	48	-	-	-	-	ADC negative reference voltage: This should be nominally the same voltage as $V_{\rm SS}$ but should be isolated to minimize noise and error. Level on this pin is used as a reference for ADC.
VREFP	64	-	-	-	-	ADC positive reference voltage: This should be nominally the same voltage as $V_{DDA}$ but should be isolated to minimize noise and error. Level on this pin is used as a reference for ADC. This pin should be tied to 3.3 V if the ADC is not used.
V <sub>SSA</sub>	55	-	-	-	-	analog ground: 0 V reference. This should nominally be the same voltage as $V_{SS}$ , but should be isolated to minimize noise and error.
$V_{ extsf{DD}}$	10; 33; 58	8; 44	6; 29	-	-	Supply voltage to the internal regulator and the external rail. On LQFP48 and HVQFN33 packages, this pin is also connected to the 3.3 V ADC supply and reference voltage.
$V_{SS}$	7; 54	5; 41	33	-	-	Ground.

- [1] Pin state at reset for default function: I = Input; O = Output; PU = internal pull-up enabled; IA = inactive, no pull-up/down enabled; F = floating; floating pins, if not used, should be tied to ground or power to minimize power consumption.
- [2] See Figure 10 for the reset pad configuration. RESET functionality is not available in Deep power-down mode. Use the WAKEUP pin to reset the chip and wake up from Deep power-down mode. An external pull-up resistor is required on this pin for the Deep power-down mode.
- [3] 5 V tolerant pad providing digital I/O functions with configurable pull-up/pull-down resistors and configurable hysteresis (see Figure 9).
- [4] I<sup>2</sup>C-bus pins compliant with the I<sup>2</sup>C-bus specification for I<sup>2</sup>C standard mode, I<sup>2</sup>C Fast-mode, and I<sup>2</sup>C Fast-mode Plus.
- [5] 5 V tolerant pad providing digital I/O functions with configurable pull-up/pull-down resistors and configurable hysteresis (see Figure 9); includes high-current output driver.
- [6] 5 V tolerant pad providing digital I/O functions with configurable pull-up/pull-down resistors, configurable hysteresis, and analog input. When configured as a ADC input, digital section of the pad is disabled and the pin is not 5 V tolerant (see <u>Figure 9</u>); includes programmable digital input glitch filter.
- [7] WAKEUP pin. 5 V tolerant pad providing digital I/O functions with configurable pull-up/pull-down resistors, configurable hysteresis, and analog input. When configured as a ADC input, digital section of the pad is disabled and the pin is not 5 V tolerant (see Figure 9); includes digital input glitch filter.
- [8] When the system oscillator is not used, connect XTALIN and XTALOUT as follows: XTALIN can be left floating or can be grounded (grounding is preferred to reduce susceptibility to noise). XTALOUT should be left floating.

Table 109. Pin description (LPC1345/46/47 - with USB)

Symbol	LQFP64	LQFP48	HVQFN33		Reset state[1]	Туре	Description
RESET/PIO0_0	4	3	2	[2]	I; PU	I	RESET — External reset input with 20 ns glitch filter. A LOW-going pulse as short as 50 ns on this pin resets the device, causing I/O ports and peripherals to take on their default states, and processor execution to begin at address 0. This pin also serves as the debug select input. LOW level selects the JTAG boundary scan. HIGH level selects the ARM SWD debug mode.
					-	I/O	PIO0_0 — General purpose digital input/output pin.
PIO0_1/CLKOUT/ CT32B0_MAT2/ USB_FTOGGLE	5	4	3	[3]	I; PU	I/O	PIO0_1 — General purpose digital input/output pin. A LOW level on this pin during reset starts the ISP command handler or the USB device enumeration.
					-	0	CLKOUT — Clockout pin.
					-	0	CT32B0_MAT2 — Match output 2 for 32-bit timer 0.
					-	0	<b>USB_FTOGGLE</b> — USB 1 ms Start-of-Frame signal.
PIO0_2/SSEL0/	13	10	8	[3]	I; PU	I/O	PIO0_2 — General purpose digital input/output pin.
CT16B0_CAP0						I/O	SSEL0 — Slave select for SSP0.
						I	CT16B0_CAP0 — Capture input 0 for 16-bit timer 0.
PIO0_3/USB_VBUS	19	14	9	[3]	I; PU	I/O	PIO0_3 — General purpose digital input/output pin. A LOW level on this pin during reset starts the ISP command handler. A HIGH level during reset starts the USB device enumeration.
					-	I	USB_VBUS — Monitors the presence of USB bus power.
PIO0_4/SCL	20	15	10	10 [4]	IA	I/O	<b>PIO0_4</b> — General purpose digital input/output pin (open-drain).
					-	I/O	<b>SCL</b> — I <sup>2</sup> C-bus clock input/output (open-drain). High-current sink only if I <sup>2</sup> C Fast-mode Plus is selected in the I/O configuration register.
PIO0_5/SDA	21	16	11	[4]	IA	I/O	<b>PIO0_5</b> — General purpose digital input/output pin (open-drain).
					-	I/O	<b>SDA</b> — I <sup>2</sup> C-bus data input/output (open-drain). High-current sink only if I <sup>2</sup> C Fast-mode Plus is selected in the I/O configuration register.
PIO0_6/USB_CONNECT/	29	22	15	[3]	I; PU	I/O	PIO0_6 — General purpose digital input/output pin.
SCK0					-	0	USB_CONNECT — Signal used to switch an external 1.5 kΩ resistor under software control. Used with the SoftConnect USB feature.
					-	I/O	SCK0 — Serial clock for SSP0.
PIO0_7/CTS	30	23	16	<u>[5]</u>	I; PU	I/O	<b>PIO0_7</b> — General purpose digital input/output pin (high-current output driver).
					-	I	CTS — Clear To Send input for USART.
PIO0_8/MISO0/	36	27	17	[3]	I; PU	I/O	PIO0_8 — General purpose digital input/output pin.
CT16B0_MAT0					-	I/O	MISO0 — Master In Slave Out for SSP0.
					-	0	CT16B0_MAT0 — Match output 0 for 16-bit timer 0.

Table 109. Pin description (LPC1345/46/47 - with USB)

# Chapter 9: LPC1315/16/17/45/46/47 GPIO

Rev. 4 — 12 March 2013

**User manual** 

# 9.1 How to read this chapter

All GPIO registers refer to 32 pins on each port. Depending on the package type, not all pins are available, and the corresponding bits in the GPIO registers are reserved (see Table 110).

Table 110. GPIO pins available

Package	GPIO Port 0	GPIO Port 1
LQFP64	PIO0_0 to PIO0_23	PIO1_0 to PIO1_5; PIO1_7 to PIO1_8; PIO1_10 to PIO1_29
LQFP48	PIO0_0 to PIO0_23	PIO1_13 to PIO1_16; PIO1_19 to PIO1_23 to PIO1_29; PIO1_31
HVQFN (no USB)	PIO0_0 to PIO0_23	PIO1_15; PIO1_19; PIO1_23 to PIO1_24
HVQFN (USB)	PIO0_0 to PIO0_23	PIO1_15; PIO1_19

# 9.2 Basic configuration

Various register blocks must be enabled to use the GPIO port and pin interrupt features:

- For the pin interrupts, select up to 8 external interrupt pins from all GPIO port pins in the SYSCON block (<u>Table 35</u>) and enable the clock to the pin interrupt register block in the SYSAHBCLKCTRL register (<u>Table 19</u>, bit 19). The pin interrupt wake-up feature is enabled in the STARTERPO register (<u>Table 38</u>).
- For the group interrupt feature, enable the clock to the GROUP0 and GROUP1 register interfaces in the SYSAHBCLKCTRL register ((<u>Table 19</u>, bit 19). The group interrupt wake-up feature is enabled in the STARTERP1 register (<u>Table 39</u>).
- For the GPIO port registers, enable the clock to the GPIO port register in the SYSAHBCLKCTRL register (<u>Table 19</u>, bit 6).

### 9.3 Features

# 9.3.1 GPIO pin interrupt features

- Up to 8 pins can be selected from all GPIO pins as edge- or level-sensitive interrupt requests. Each request creates a separate interrupt in the NVIC.
- Edge-sensitive interrupt pins can interrupt on rising or falling edges or both.
- Level-sensitive interrupt pins can be HIGH- or LOW-active.

#### 9.3.2 **GPIO** group interrupt features

- The inputs from any number of GPIO pins can be enabled to contribute to a combined group interrupt.
- The polarity of each input enabled for the group interrupt can be configured HIGH or LOW.

UM10524

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

- Enabled interrupts can be logically combined through an OR or AND operation.
- Two group interrupts are supported to reflect two distinct interrupt patterns.
- The GPIO group interrupts can wake up the part from sleep, deep-sleep or power-down modes.

# 9.3.3 GPIO port features

- GPIO pins can be configured as input or output by software.
- · All GPIO pins default to inputs with interrupt disabled at reset.
- Pin registers allow pins to be sensed and set individually.

### 9.4 Introduction

The GPIO pins can be used in several ways to set pins as inputs or outputs and use the inputs as combinations of level and edge sensitive interrupts.

# 9.4.1 GPIO pin interrupts

From all available GPIO pins, up to eight pins can be selected in the system control block to serve as external interrupt pins (see <u>Table 35</u>). The external interrupt pins are connected to eight individual interrupts in the NVIC and are created based on rising or falling edges or on the input level on the pin.

# 9.4.2 GPIO group interrupt

For each port/pin connected to one of the two the GPIO Grouped Interrupt blocks (GROUP0 and GROUP1), the GPIO grouped interrupt registers determine which pins are enabled to generate interrupts and what the active polarities of each of those inputs are.

The GPIO grouped interrupt registers also select whether the interrupt output will be level or edge triggered and whether it will be based on the OR or the AND of all of the enabled inputs.

When the designated pattern is detected on the selected input pins, the GPIO grouped interrupt block will generate an interrupt. If the part is in a power-savings mode it will first asynchronously wake the part up prior to asserting the interrupt request. The interrupt request line can be cleared by writing a one to the interrupt status bit in the control register.

# 9.4.3 GPIO port

The GPIO port registers can be used to configure each GPIO pin as input or output and read the state of each pin if the pin is configured as input or set the state of each pin if the pin is configured as output.

# 9.5 Register description

The GPIO consists of the following blocks:

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

- The GPIO pin interrupts block at address 0x4004 C000. Registers in this block enable
  the up to 8 pin interrupts selected in the syscon block PINTSEL registers (see
   <u>Table 35</u>) and configure the level and edge sensitivity for each selected pin interrupt.
   The GPIO interrupt registers are listed in <u>Table 111</u> and <u>Section 9.5.1</u>
- The GPIO GROUP0 interrupt block at address 0x4005 C000. Registers in this block allow to configure any pin on port 0 and 1 to contribute to a combined interrupt. The GPIO GROUP0 registers are listed in Table 112 and Section 9.5.2.
- The GPIO GROUP1 interrupt block at address 0x4006 0000. Registers in this block allow to configure any pin on port 0 and 1 to contribute to a combined interrupt. The GPIO GROUP1 registers are listed in Table 113 and Section 9.5.2.
- The GPIO port block at address 0x5000 0000. Registers in this block allow to read and write to port pins and configure port pins as inputs or outputs. The GPIO port registers are listed in Table 114 and Section 9.5.3.

**Note:** In all GPIO registers, bits that are not shown are **reserved**.

<sup>[1]</sup> ext indicates that the data read after reset depends on the state of the pin, which in turn may depend on an external source.

# 9.5.1 GPIO pin interrupts register description

### 9.5.1.1 Pin interrupt mode register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the ISEL register determines whether the interrupt is edge or level sensitive.

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 115. Pin interrupt mode register (ISEL, address 0x4004 C000) bit description

Bit	Symbol	Description	Reset value	Access
7:0	PMODE	Selects the interrupt mode for each pin interrupt. Bit n configures the pin interrupt selected in PINTSELn.  0 = Edge sensitive  1 = Level sensitive	0	R/W
31:8	-	Reserved.	-	-

#### 9.5.1.2 Pin interrupt level (rising edge) interrupt enable register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the IENR register enables the interrupt depending on the pin interrupt mode configured in the ISEL register:

- If the pin interrupt mode is edge sensitive (PMODE = 0), the rising edge interrupt is enabled.
- If the pin interrupt mode is level sensitive (PMODE = 1), the level interrupt is enabled. The IENF register configures the active level (HIGH or LOW) for this interrupt.

Table 116. Pin interrupt level (rising edge) interrupt enable register (IENR, address 0x4004 C004) bit description

		, and accompany		
Bit	Symbol	Description	Reset value	Access
7:0	ENRL	Enables the rising edge or level interrupt for each pin interrupt. Bit n configures the pin interrupt selected in PINTSELn.  0 = Disable rising edge or level interrupt.  1 = Enable rising edge or level interrupt.	0	R/W
31:8	-	Reserved.	-	-

### 9.5.1.3 Pin interrupt level (rising edge) interrupt set register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the SIENR register sets the corresponding bit in the IENR register depending on the pin interrupt mode configured in the ISEL register:

- If the pin interrupt mode is edge sensitive (PMODE = 0), the rising edge interrupt is set.
- If the pin interrupt mode is level sensitive (PMODE = 1), the level interrupt is set.

Table 117. Pin interrupt level (rising edge) interrupt set register (SIENR, address 0x4004 C008) bit description

Bit	Symbol	Description	Reset value	Access
7:0	SETENRL	Ones written to this address set bits in the IENR, thus enabling interrupts. Bit n sets bit n in the IENR register.  0 = No operation.  1 = Enable rising edge or level interrupt.	NA	WO
31:8	-	Reserved.	-	-

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

### 9.5.1.4 Pin interrupt level (rising edge interrupt) clear register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the CIENR register clears the corresponding bit in the IENR register depending on the pin interrupt mode configured in the ISEL register:

- If the pin interrupt mode is edge sensitive (PMODE = 0), the rising edge interrupt is cleared.
- If the pin interrupt mode is level sensitive (PMODE = 1), the level interrupt is cleared.

Table 118. Pin interrupt level (rising edge interrupt) clear register (CIENR, address 0x4004 C00C) bit description

Bit	Symbol	Description	Reset value	Access
7:0	CENRL	Ones written to this address clear bits in the IENR, thus disabling the interrupts. Bit n clears bit n in the IENR register.  0 = No operation.  1 = Disable rising edge or level interrupt.	NA	WO
31:8	-	Reserved.	-	-

#### 9.5.1.5 Pin interrupt active level (falling edge) interrupt enable register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the IENF register enables the falling edge interrupt or the configures the level sensitivity depending on the pin interrupt mode configured in the ISEL register:

- If the pin interrupt mode is edge sensitive (PMODE = 0), the falling edge interrupt is enabled.
- If the pin interrupt mode is level sensitive (PMODE = 1), the active level of the level interrupt (HIGH or LOW) is configured.

Table 119. Pin interrupt active level (falling edge) interrupt enable register (IENF, address 0x4004 C010) bit description

Bit	Symbol	Description	Reset value	Access
7:0	ENAF	Enables the falling edge or configures the active level interrupt for each pin interrupt. Bit n configures the pin interrupt selected in PINTSELn.  0 = Disable falling edge interrupt or set active interrupt level LOW.  1 = Enable falling edge interrupt enabled or set active interrupt level HIGH.	0	R/W
31:8	-	Reserved.	-	-

# 9.5.1.6 Pin interrupt active level (falling edge) interrupt set register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the SIENF register sets the corresponding bit in the IENF register depending on the pin interrupt mode configured in the ISEL register:

• If the pin interrupt mode is edge sensitive (PMODE = 0), the falling edge interrupt is set.

UM10524

123 of 416

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

 If the pin interrupt mode is level sensitive (PMODE = 1), the HIGH-active interrupt is selected.

Table 120. Pin interrupt active level (falling edge interrupt) set register (SIENF, address 0x4004 C014) bit description

		7		
Bit	Symbol	Description	Reset value	Access
7:0	SETENAF	Ones written to this address set bits in the IENF, thus enabling interrupts. Bit n sets bit n in the IENF register.  0 = No operation.  1 = Select HIGH-active interrupt or enable falling edge interrupt.	NA	WO
31:8	-	Reserved.	-	-

### 9.5.1.7 Pin interrupt active level (falling edge interrupt) clear register

For each of the 8 pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>), one bit in the CIENF register sets the corresponding bit in the IENF register depending on the pin interrupt mode configured in the ISEL register:

- If the pin interrupt mode is edge sensitive (PMODE = 0), the falling edge interrupt is cleared.
- If the pin interrupt mode is level sensitive (PMODE = 1), the LOW-active interrupt is selected.

Table 121. Pin interrupt active level (falling edge) interrupt clear register (CIENF, address 0x4004 C018) bit description

Bit	Symbol	Description	Reset value	Access
7:0	CENAF	Ones written to this address clears bits in the IENF, thus disabling interrupts. Bit n clears bit n in the IENF register.  0 = No operation.  1 = LOW-active interrupt selected or falling edge interrupt disabled.	NA	WO
31:8	-	Reserved.	-	-

#### 9.5.1.8 Pin interrupt rising edge register

This register contains ones for pin interrupts selected in the PINTSELn registers (see <u>Table 35</u>) on which a rising edge has been detected. Writing ones to this register clears rising edge detection. Ones in this register assert an interrupt request for pins that are enabled for rising-edge interrupts. All edges are detected for all pins selected by the PINTSELn registers, regardless of whether they are interrupt-enabled.

# Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 122. Pin interrupt rising edge register (RISE, address 0x4004 C01C) bit description

Bit	Symbol	Description	Reset value	Access
7:0	RDET	Rising edge detect. Bit n detects the rising edge of the pin selected in PINTSELn.  Read 0: No rising edge has been detected on this pin since Reset or the last time a one was written to this bit.  Write 0: no operation.  Read 1: a rising edge has been detected since Reset or the last time a one was written to this bit.  Write 1: clear rising edge detection for this pin.	0	R/W
31:8	-	Reserved.	-	-

### 9.5.1.9 Pin interrupt falling edge register

This register contains ones for pin interrupts selected in the PINTSELn registers (see Table 35) on which a falling edge has been detected. Writing ones to this register clears falling edge detection. Ones in this register assert an interrupt request for pins that are enabled for falling-edge interrupts. All edges are detected for all pins selected by the PINTSELn registers, regardless of whether they are interrupt-enabled.

Table 123. Pin interrupt falling edge register (FALL, address 0x4004 C020) bit description

				•
Bit	Symbol	Description	Reset value	Access
7:0	FDET	Falling edge detect. Bit n detects the falling edge of the pin selected in PINTSELn.  Read 0: No falling edge has been detected on this pin since Reset or the last time a one was written to this bit.  Write 0: no operation.  Read 1: a falling edge has been detected since Reset or the last time a one was written to this bit.  Write 1: clear falling edge detection for this pin.	0	R/W
31:8	-	Reserved.	-	-

#### 9.5.1.10 Pin interrupt status register

Reading this register returns ones for pin interrupts that are currently requesting an interrupt. For pins identified as edge-sensitive in the Interrupt Select register, writing ones to this register clears both rising- and falling-edge detection for the pin. For level-sensitive pins, writing ones inverts the corresponding bit in the Active level register, thus switching the active level on the pin.

# Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 124. Pin interrupt status register (IST address 0x4004 C024) bit description

			-	
Bit	Symbol	Description	Reset value	Access
7:0	PSTAT	Pin interrupt status. Bit n returns the status, clears the edge interrupt, or inverts the active level of the pin selected in PINTSELn.  Read 0: interrupt is not being requested for this interrupt pin. Write 0: no operation.  Read 1: interrupt is being requested for this interrupt pin.  Write 1 (edge-sensitive): clear rising- and falling-edge detection for this pin.  Write 1 (level-sensitive): switch the active level for this pin (in the IENF register).	0	R/W
31:8	-	Reserved.	-	-

# 9.5.2 GPIO GROUP0/GROUP1 interrupt register description

# 9.5.2.1 Grouped interrupt control register

Table 125. GPIO grouped interrupt control register (CTRL, addresses 0x4005 C000 (GROUP0 INT) and 0x4006 0000 (GROUP1 INT)) bit description

Bit	Symbol	Value	Description	Reset value
0	INT		Group interrupt status. This bit is cleared by writing a one to it. Writing zero has no effect.	0
		0	No interrupt request is pending.	
		1	Interrupt request is active.	
1	COMB		Combine enabled inputs for group interrupt	0
		0	OR functionality: A grouped interrupt is generated when any one of the enabled inputs is active (based on its programmed polarity).	
		1	AND functionality: An interrupt is generated when all enabled bits are active (based on their programmed polarity).	
2	TRIG		Group interrupt trigger	0
		0	Edge-triggered	
		1	Level-triggered	
31:3	-	-	Reserved	0

### 9.5.2.2 GPIO grouped interrupt port polarity registers

The grouped interrupt port polarity registers determine how the polarity of each enabled pin contributes to the grouped interrupt. Each port is associated with its own port polarity register, and the values of both registers together determine the grouped interrupt.

### Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 126. GPIO grouped interrupt port 0 polarity registers (PORT\_POL0, addresses 0x4005 C020 (GROUP0 INT) and 0x4006 0020 (GROUP1 INT)) bit description

Bit	Symbol	Description	Reset value	Access
31:0	POL0	Configure pin polarity of port 0 pins for group interrupt. Bit n corresponds to pin P0_n of port 0. $0 = \text{the pin is active LOW}$ . If the level on this pin is LOW, the pin contributes to the group interrupt. $1 = \text{the pin is active HIGH}$ . If the level on this pin is HIGH, the pin contributes to the group interrupt.	1	-

Table 127. GPIO grouped interrupt port 1 polarity registers (PORT\_POL1, addresses 0x4005 C024 (GROUP0 INT) and 0x4006 0024 (GROUP1 INT)) bit description

Bit	Symbol	Description	Reset value	Access
31:0	POL1	Configure pin polarity of port 1 pins for group interrupt. Bit n corresponds to pin P1_n of port 1.  0 = the pin is active LOW. If the level on this pin is LOW, the pin contributes to the group interrupt.  1 = the pin is active HIGH. If the level on this pin is HIGH, the pin contributes to the group interrupt.	1	-

#### 9.5.2.3 GPIO grouped interrupt port enable registers

The grouped interrupt port enable registers enable the pins which contribute to the grouped interrupt. Each port is associated with its own port enable register, and the values of both registers together determine which pins contribute to the grouped interrupt.

Table 128. GPIO grouped interrupt port 0 enable registers (PORT\_ENA0, addresses 0x4005 C040 (GROUP0 INT) and 0x4006 0040 (GROUP1 INT)) bit description

Bit	Symbol	Description	Reset value	Access
31:0	ENA0	Enable port 0 pin for group interrupt. Bit n corresponds to pin P0_n of port 0.  0 = the port 0 pin is disabled and does not contribute to the grouped interrupt.  1 = the port 0 pin is enabled and contributes to the grouped interrupt.	0	-

Table 129. GPIO grouped interrupt port 1 enable registers (PORT ENA1, addresses 0x4005 C044 (GROUP0 INT) and 0x4006 0044 (GROUP1 INT)) bit description

Bit	Symbol	Description	Reset value	Access
31:0	ENA1	Enable port 1 pin for group interrupt. Bit n corresponds to pin P1_n of port 0.  0 = the port 1 pin is disabled and does not contribute to the grouped interrupt.  1 = the port 1 pin is enabled and contributes to the grouped interrupt.	0	-

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

# 9.5.3 GPIO port register description

### 9.5.3.1 GPIO port byte pin registers

Each GPIO pin has a byte register in this address range. Software typically reads and writes bytes to access individual pins, but can read or write halfwords to sense or set the state of two pins, and read or write words to sense or set the state of four pins.

Table 130. GPIO port 0 byte pin registers (B0 to B23, addresses 0x5000 0000 to 0x5000 0018) bit description

Bit	Symbol	Description	Reset value	Access
0	PBYTE	Read: state of the pin P0_n, regardless of direction, masking, or alternate function, except that pins configured as analog I/O always read as 0. Write: loads the pin's output bit.	ext	R/W
7:1		Reserved (0 on read, ignored on write)	0	-

Table 131. GPIO port 1 byte pin registers (B32 to B63, addresses 0x5000 0020 to 0x5000 002F) bit description

Bit	Symbol	Description	Reset value	Access
0	PBYTE	Read: state of the pin P1_n, regardless of direction, masking, or alternate function, except that pins configured as analog I/O always read as 0.  Write: loads the pin's output bit.	ext	R/W
7:1		Reserved (0 on read, ignored on write)	0	-

#### 9.5.3.2 GPIO port word pin registers

Each GPIO pin has a word register in this address range. Any byte, halfword, or word read in this range will be all zeros if the pin is low or all ones if the pin is high, regardless of direction, masking, or alternate function, except that pins configured as analog I/O always read as zeros. Any write will clear the pin's output bit if the value written is all zeros, else it will set the pin's output bit.

Table 132. GPIO port 0 word pin registers (W0 to W23, addresses 0x5000 1000 to 0x5000 1060) bit description

Bit	Symbol	Description	Reset value	Access
31:0	PWORD	Read 0: pin is LOW. Write 0: clear output bit. Read 0xFFFF FFFF: pin is HIGH. Write any value 0x0000 0001 to 0xFFFF FFFF: set output bit.  Remark: Only 0 or 0xFFFF FFFF can be read. Writing any value other than 0 will set the output bit.	ext	R/W

# Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 133. GPIO port 1 word pin registers (W32 to W63, addresses 0x5000 1080 to 0x5000 10FC) bit description

Bit	Symbol	Description	Reset value	Access
31:0	PWORD	Read 0: pin is LOW. Write 0: clear output bit. Read 0xFFFF FFFF: pin is HIGH. Write any value 0x0000 0001 to 0xFFFF FFFF: set output bit.	ext	R/W
		<b>Remark:</b> Only 0 or 0xFFFF FFFF can be read. Writing any value other than 0 will set the output bit.		

# 9.5.3.3 GPIO port direction registers

Each GPIO port has one direction register for configuring the port pins as inputs or outputs.

Table 134. GPIO direction port 0 register (DIR0, address 0x5000 2000) bit description

Bit	Symbol	Description	Reset value	Access
31:0	DIRP0	Selects pin direction for pin P0_n (bit 0 = P0_0, bit 1 = P0_1,, bit 31 = P0_31).  0 = input.  1 = output.	0	R/W

Table 135. GPIO direction port 1 register (DIR1, address 0x5000 2004) bit description

Bit	Symbol	Description	Reset value	Access
31:0	DIRP1	Selects pin direction for pin P1_n (bit 0 = P1_0, bit 1 = P1_1,, bit 31 = P1_31).  0 = input.  1 = output.	0	R/W

#### 9.5.3.4 GPIO port mask registers

These registers affect writing and reading the MPORT registers. Zeroes in these registers enable reading and writing; ones disable writing and result in zeros in corresponding positions when reading.

Table 136. GPIO mask port 0 register (MASK0, address 0x5000 2080) bit description

Bit	Symbol	Description	Reset value	Access
31:0	MASKP0	Controls which bits corresponding to P0_n are active in the P0MPORT register (bit 0 = P0_0, bit 1 = P0_1,, bit 31 = P0_31).  0 = Read MPORT: pin state; write MPORT: load output bit.  1 = Read MPORT: 0; write MPORT: output bit not affected.	0	R/W

# Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 137. GPIO mask port 1 register (MASK1, address 0x5000 2084) bit description

Bit	Symbol	Description	Reset value	Access
31:0	MASKP1	Controls which bits corresponding to P1_n are active in the P1MPORT register (bit 0 = P1_0, bit 1 = P1_1,, bit 31 = P1_31).  0 = Read MPORT: pin state; write MPORT: load output bit.  1 = Read MPORT: 0; write MPORT: output bit not affected.	0	R/W

### 9.5.3.5 GPIO port pin registers

Reading these registers returns the current state of the pins read, regardless of direction, masking, or alternate functions, except that pins configured as analog I/O always read as 0s. Writing these registers loads the output bits of the pins written to, regardless of the Mask register.

Table 138. GPIO port 0 pin register (PIN0, address 0x5000 2100) bit description

Bit	Symbol	Description	Reset value	Access
31:0	PORT0	Reads pin states or loads output bits (bit 0 = P0_0, bit 1 = P0_1,, bit 31 = P0_31).  0 = Read: pin is low; write: clear output bit.  1 = Read: pin is high; write: set output bit.	ext	R/W

Table 139. GPIO port 1 pin register (PIN1, address 0x5000 2104) bit description

Bit	Symbol	Description	Reset value	Access
31:0	PORT1	Reads pin states or loads output bits (bit 0 = P1_0, bit 1 = P1_1,, bit 31 = P1_31).  0 = Read: pin is low; write: clear output bit.  1 = Read: pin is high; write: set output bit.	ext	R/W

#### 9.5.3.6 GPIO masked port pin registers

These registers are similar to the PORT registers, except that the value read is masked by ANDing with the inverted contents of the corresponding MASK register, and writing to one of these registers only affects output register bits that are enabled by zeros in the corresponding MASK register

Table 140. GPIO masked port 0 pin register (MPIN0, address 0x5000 2180) bit description

Bit	Symbol	Description	Reset value	Access
31:0	MPORTP0	Masked port register (bit 0 = P0_0, bit 1 = P0_1,, bit 31 = P0_31).  0 = Read: pin is LOW and/or the corresponding bit in the MASK register is 1; write: clear output bit if the corresponding bit in the MASK register is 0.  1 = Read: pin is HIGH and the corresponding bit in the MASK register is 0; write: set output bit if the corresponding bit in the MASK register is 0.	ext	R/W

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 141. GPIO masked port 1 pin register (MPIN1, address 0x5000 2184) bit description

Bit	Symbol	Description	Reset value	Access
31:0	MPORTP1	Masked port register (bit 0 = P1_0, bit 1 = P1_1,, bit 31 = P1_31).  0 = Read: pin is LOW and/or the corresponding bit in the MASK register is 1; write: clear output bit if the corresponding bit in the MASK register is 0.  1 = Read: pin is HIGH and the corresponding bit in the MASK register is 0; write: set output bit if the corresponding bit in the MASK register is 0.	ext	R/W

# 9.5.3.7 GPIO port set registers

Output bits can be set by writing ones to these registers, regardless of MASK registers. Reading from these register returns the port's output bits, regardless of pin directions.

Table 142. GPIO set port 0 register (SET0, address 0x5000 2200) bit description

Bit	Symbol	Description	Reset value	Access
31:0	SETP0	Read or set output bits.  0 = Read: output bit: write: no operation.  1 = Read: output bit; write: set output bit.	0	R/W

Table 143. GPIO set port 1 register (SET1, address 0x5000 2204) bit description

Bit	Symbol	Description	Reset value	Access
31:0	SETP1	Read or set output bits.  0 = Read: output bit: write: no operation.  1 = Read: output bit; write: set output bit.	0	R/W

### 9.5.3.8 GPIO port clear registers

Output bits can be cleared by writing ones to these write-only registers, regardless of MASK registers.

Table 144. GPIO clear port 0 register (CLR0, address 0x5000 2280) bit description

Bit	Symbol	Description	Reset value	Access
31:0	CLRP0	Clear output bits: 0 = No operation. 1 = Clear output bit.	NA	WO

Table 145. GPIO clear port 1 register (CLR1, address 0x5000 2284) bit description

Bit	Symbol	Description	Reset value	Access
31:0	CLRP1	Clear output bits: 0 = No operation. 1 = Clear output bit.	NA	WO

# 9.5.3.9 GPIO port toggle registers

Output bits can be toggled/inverted/complemented by writing ones to these write-only registers, regardless of MASK registers.

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

Table 146. GPIO toggle port 0 register (NOT0, address 0x5000 2300) bit description

Bit	Symbol	Description	Reset value	Access

# 9.6 Functional description

# 9.6.1 Reading pin state

Software can read the state of all GPIO pins except those selected for analog input or output in the "I/O Configuration" logic. A pin does not have to be selected for GPIO in "I/O Configuration" in order to read its state. There are four ways to read pin state:

- The state of a single pin can be read with 7 high-order zeros from a Byte Pin register.
- The state of a single pin can be read in all bits of a byte, halfword, or word from a Word Pin register.
- The state of multiple pins in a port can be read as a byte, halfword, or word from a PORT register.
- The state of a selected subset of the pins in a port can be read from a Masked Port (MPORT) register. Pins having a 1 in the port's Mask register will read as 0 from its MPORT register.

#### 9.6.2 GPIO output

Each GPIO pin has an output bit in the GPIO block. These output bits are the targets of write operations "to the pins". Two conditions must be met in order for a pin's output bit to be driven onto the pin:

- 1. The pin must be selected for GPIO operation in the "I/O Configuration" block, and
- 2. the pin must be selected for output by a 1 in its port's DIR register.

If either or both of these conditions is (are) not met, "writing to the pin" has no effect.

There are seven ways to change GPIO output bits:

- Writing to a Byte Pin register loads the output bit from the least significant bit.
- Writing to a Word Pin register loads the output bit with the OR of all of the bits written. (This feature follows the definition of "truth" of a multi-bit value in programming languages.)
- Writing to a port's PORT register loads the output bits of all the pins written to.

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

- Writing to a port's MPORT register loads the output bits of pins identified by zeros in corresponding positions of the port's MASK register.
- Writing ones to a port's SET register sets output bits.
- Writing ones to a port's CLR register clears output bits.
- Writing ones to a port's NOT register toggles/complements/inverts output bits.

The state of a port's output bits can be read from its SET register. Reading any of the registers described in <u>9.6.1</u> returns the state of pins, regardless of their direction or alternate functions.

#### 9.6.3 Masked I/O

A port's MASK register defines which of its pins should be accessible in its MPORT register. Zeroes in MASK enable the corresponding pins to be read from and written to MPORT. Ones in MASK force a pin to read as 0 and its output bit to be unaffected by writes to MPORT. When a port's MASK register contains all zeros, its PORT and MPORT registers operate identically for reading and writing.

Applications in which interrupts can result in Masked GPIO operation, or in task switching among tasks that do Masked GPIO operation, must treat code that uses the Mask register as a protected/restricted region. This can be done by interrupt disabling or by using a semaphore.

The simpler way to protect a block of code that uses a MASK register is to disable interrupts before setting the MASK register, and re-enable them after the last operation that uses the MPORT or MASK register.

More efficiently, software can dedicate a semaphore to the MASK registers, and set/capture the semaphore controlling exclusive use of the MASK registers before setting the MASK registers, and release the semaphore after the last operation that uses the MPORT or MASK registers.

### 9.6.4 GPIO Interrupts

Two separate GPIO interrupt facilities are provided. With pin interrupts, up to eight GPIO pins can each have separately-vectored, edge- or level-sensitive interrupts.

With group interrupts, any subset of the pins in each port can be selected to contribute to a common interrupt. Any of the pin and port interrupts can be enabled to wake the part from Deep-sleep mode or Power-down mode.

#### 9.6.4.1 Pin interrupts

In this interrupt facility, up to 8 pins are identified as interrupt sources by the Pin Interrupt Select registers (PINTSEL0-7). All registers in the pin interrupt block contain 8 bits, corresponding to the pins called out by the PINTSEL0-7 registers. The ISEL register defines whether each interrupt pin is edge- or level-sensitive. The RISE and FALL registers detect edges on each interrupt pin, and can be written to clear (and set) edge detection. The IST register indicates whether each interrupt pin is currently requesting an interrupt, and this register can also be written to clear interrupts.

#### Chapter 9: LPC1315/16/17/45/46/47 GPIO

The other pin interrupt registers play different roles for edge-sensitive and level-sensitive pins, as described in Table 148.

Table 148. Pin interrupt registers for edge- and level-sensitive pins

Name	Edge-sensitive function	Level-sensitive function
IENR	Enables rising-edge interrupts.	Enables level interrupts.
SIENR	Write to enable rising-edge interrupts.	Write to enable level interrupts.
CIENR	Write to disable rising-edge interrupts.	Write to disable level interrupts.
IENF	Enables falling-edge interrupts.	Selects active level.
SIENF	Write to enable falling-edge interrupts.	Write to select high-active.
CIENF	Write to disable falling-edge interrupts.	Write to select low-active.

### 9.6.4.2 Group interrupts

In this interrupt facility, an interrupt can be requested for each port, based on any selected subset of pins within each port. The pins that contribute to each port interrupt are selected by 1s in the port's Enable register, and an interrupt polarity can be selected for each pin in the port's Polarity register. The level on each pin is exclusive-ORed with its polarity bit and the result is ANDed with its enable bit, and these results are then inclusive-ORed among all the pins in the port, to create the port's raw interrupt request.

The raw interrupt request from each of the two group interrupts is sent to the NVIC, which can be programmed to treat it as level- or edge-sensitive (see Section 6.4), or it can be edge-detected by the wake-up interrupt logic (see Table 39).

# 9.6.5 Recommended practices

The following lists some recommended uses for using the GPIO port registers:

- For initial setup after Reset or re-initialization, write the PORT register(s).
- To change the state of one pin, write a Byte Pin or Word Pin register.
- To change the state of multiple pins at a time, write the SET and/or CLR registers.
- To change the state of multiple pins in a tightly controlled environment like a software state machine, consider using the NOT register. This can require less write operations than SET and CLR.
- To read the state of one pin, read a Byte Pin or Word Pin register.
- To make a decision based on multiple pins, read and mask a PORT register.

# **UM10524**

# Chapter 10: LPC1345/46/47 USB2.0 device controller

Rev. 4 — 12 March 2013

**User manual** 

# 10.1 How to read this chapter

The USB block is available on the LPC1345/46/47 parts.

# 10.2 Basic configuration

- Pins: Configure the USB pins in the IOCON register block.
- In the SYSAHBCLKCTRL register, enable the clock to the USB controller register interface by setting bit 14 and to the USB RAM by setting bit 27 (see <u>Table 19</u>).
- Power: Enable the power to the USB PHY and to the USB PLL, if used, in the PDRUNCFG register (<u>Table 42</u>).
- Configure the USB main clock (see <u>Table 25</u>).
- Configure the USB wake-up signal (see Section 10.7.6) if needed.

#### 10.3 Features

- USB2.0 full-speed device controller.
- Supports 10 physical (5 logical) endpoints including one control endpoint.
- Single and double-buffering supported.
- Each non-control endpoint supports bulk, interrupt, or isochronous endpoint types.
- Supports wake-up from Deep-sleep mode on USB activity and remote wake-up.
- Supports SoftConnect.

# 10.4 General description

The Universal Serial Bus (USB) is a four-wire bus that supports communication between a host and one or more (up to 127) peripherals. The host controller allocates the USB bandwidth to attached devices through a token-based protocol. The bus supports hot plugging and dynamic configuration of the devices. All transactions are initiated by the host controller.

The host schedules transactions in 1 ms frames. Each frame contains a Start-Of-Frame (SOF) marker and transactions that transfer data to or from device endpoints. Each device can have a maximum of 16 logical or 32 physical endpoints. The LPC1315/16/17/45/46/47 device controller supports up to 10 physical endpoints. There are four types of transfers defined for the endpoints. Control transfers are used to configure the device.

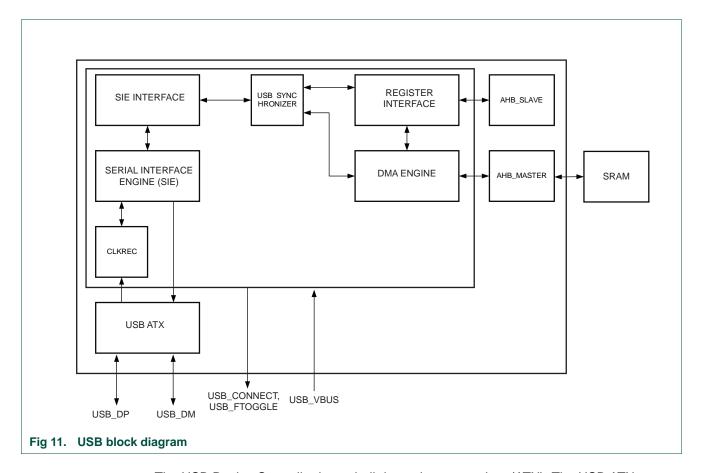

Interrupt transfers are used for periodic data transfer. Bulk transfers are used when the latency of transfer is not critical. Isochronous transfers have guaranteed delivery time but no error correction.

For more information on the Universal Serial Bus, see the USB Implementers Forum website.

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

The USB device controller on the LPC1315/16/17/45/46/47 enables full-speed (12 Mb/s) data exchange with a USB host controller.

Figure 11 shows the block diagram of the USB device controller.

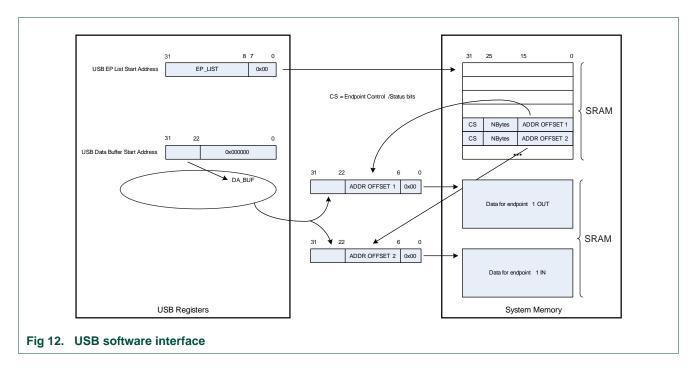

The USB Device Controller has a built-in analog transceiver (ATX). The USB ATX sends/receives the bi-directional USB\_DP and USB\_DM signals of the USB bus.

The SIE implements the full USB protocol layer. It is completely hardwired for speed and needs no software intervention. It handles transfer of data between the endpoint buffers in USB RAM and the USB bus. The functions of this block include: synchronization pattern recognition, parallel/serial conversion, bit stuffing/de-stuffing, CRC checking/generation, PID verification/generation, address recognition, and handshake evaluation/generation.

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

#### 10.4.1 USB software interface

# 10.4.2 Fixed endpoint configuration

<u>Table 149</u> shows the supported endpoint configurations. The packet size is configurable up to the maximum value shown in <u>Table 149</u> for each type of end point.

Table 149. Fixed endpoint configuration

		J			
Logical endpoint	Physical endpoint	Endpoint type	Direction	Max packet size (byte)	Double buffer
0	0	Control	Out	64	No
0	1	Control	In	64	No
1	2	Interrupt/Bulk/Isochronous	Out	64/64/1023	Yes
1	3	Interrupt/Bulk/Isochronous	In	64/64/1023	Yes
2	4	Interrupt/Bulk/Isochronous	Out	64/64/1023	Yes
2	5	Interrupt/Bulk/Isochronous	In	64/64/1023	Yes
3	6	Interrupt/Bulk/Isochronous	Out	64/64/1023	Yes
3	7	Interrupt/Bulk/Isochronous	In	64/64/1023	Yes
4	8	Interrupt/Bulk/Isochronous	Out	64/64/1023	Yes
4	9	Interrupt/Bulk/Isochronous	In	64/64/1023	Yes

#### 10.4.3 SoftConnect

The connection to the USB is accomplished by bringing USB\_DP (for a full-speed device) HIGH through a 1.5 kOhm pull-up resistor. The SoftConnect feature can be used to allow software to finish its initialization sequence before deciding to establish connection to the USB. Re-initialization of the USB bus connection can also be performed without having to unplug the cable.

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

To use the SoftConnect feature, the CONNECT signal should control an external switch that connects the 1.5 kOhm resistor between USB\_DP and  $V_{DD}$  (+3.3 V). Software can then control the CONNECT signal by writing to the DCON bit in the DEVCMDSTAT register.

# 10.4.4 Interrupts

The USB controller has two interrupt lines USB\_Int\_Req\_IRQ and USB\_Int\_Req\_FIQ. Software can program the corresponding bit in the USB interrupt routing register to route the interrupt condition to one of these entries in the NVIC table <u>Table 53</u>. An interrupt is generated by the hardware if both the interrupt status bit and the corresponding interrupt enable bit are set. The interrupt status bit is set by hardware if the interrupt condition occurs (irrespective of the interrupt enable bit setting).

# 10.4.5 Suspend and resume

The USB protocol insists on power management by the USB device. This becomes even more important if the device draws power from the bus (bus-powered device). The following constraints should be met by the bus-powered device.

- A device in the non-configured state should draw a maximum of 100mA from the USB bus.
- A configured device can draw only up to what is specified in the Max Power field of the configuration descriptor. The maximum value is 500 mA.
- A suspended device should draw a maximum of 500 μA.

A device will go into the L2 suspend state if there is no activity on the USB bus for more than 3 ms. A suspended device wakes up, if there is transmission from the host (host-initiated wake up). The USB controller on the LPC1315/16/17/45/46/47 also supports software initiated remote wake-up. To initiate remote wake-up, software on the device must enable all clocks and clear the suspend bit. This will cause the hardware to generate a remote wake-up signal upstream.

The USB controller supports Link Power Management. Link Power Management defines an additional link power management state L1 that supplements the existing L2 state by utilizing most of the existing suspend/resume infrastructure but provides much faster transitional latencies between L1 and L0 (On).

The assertion of USB suspend signal indicates that there was no activity on the USB bus for the last 3 ms. At this time an interrupt is sent to the processor on which the software can start preparing the device for suspend.

If there is no activity for the next 2 ms, the USB need\_clock signal will go low. This indicates that the USB main clock can be switched off.

When activity is detected on the USB bus, the USB suspend signal is deactivated and USB need\_clock signal is activated. This process is fully combinatorial and hence no USB main clock is required to activate the USB need\_clock signal.

# 10.4.6 Frame toggle output

The USB\_FTOGGLE output pin reflects the 1 kHz clock derived from the incoming Start of Frame tokens sent by the USB host.

UM10524

# Chapter 10: LPC1345/46/47 USB2.0 device controller

# 10.4.7 Clocking

The LPC1315/16/17/45/46/47 USB device controller has the following clock connections:

- USB main clock: The USB main clock is the 48 MHz +/- 500 ppm clock from the
  dedicated USB PLL or the main clock (see <u>Table 25</u>). If the main clock is used, the
  system PLL output must be 48 MHz and derived from the system oscillator. The USB
  main clock is used to recover the 12 MHz clock from the USB bus.
- AHB clock: This is the AHB system bus clock. The minimum frequency of the AHB clock is 16 MHz when the USB device controller is receiving or transmitting USB packets.

# 10.5 Pin description

The device controller can access one USB port.

Table 150. USB device pin description

Name	Direction	Description
$V_{BUS}$	I	$V_{\mbox{\footnotesize BUS}}$ status input. When this function is not enabled via its corresponding IOCON register, it is driven HIGH internally.
USB_CONNECT	0	SoftConnect control signal.
USB_FTOGGLE	0	USB 1 ms SoF signal.
USB_DP	I/O	Positive differential data.
USB_DM	I/O	Negative differential data.

		1	Both acknowledged and NAKed packets generate interrupts.		

### Chapter 10: LPC1345/46/47 USB2.0 device controller

Table 152. USB Device Command/Status register (DEVCMDSTAT, address 0x4008 0000) bit description

Bit	Symbol	Value	Description	Reset value	Access
16	DCON		Device status - connect.  The connect bit must be set by SW to indicate that the device must signal a connect. The pull-up resistor on USB_DP will be enabled when this bit is set and the VbusDebounced bit is one.	0	RW
17	DSUS		Device status - suspend.  The suspend bit indicates the current suspend state. It is set to 1 when the device hasn't seen any activity on its upstream port for more than 3 milliseconds. It is reset to 0 on any activity. When the device is suspended (Suspend bit DSUS = 1) and the software writes a 0 to it, the device will generate a remote wake-up. This will only happen when the device is connected (Connect bit = 1). When the device is not connected or not suspended, a writing a 0 has no effect. Writing a 1 never has an effect.	0	RW
18	-		Reserved.	0	RO
19	LPM_SUS		Device status - LPM Suspend.  This bit represents the current LPM suspend state. It is set to 1 by HW when the device has acknowledged the LPM request from the USB host and the Token Retry Time of 10us has elapsed. When the device is in the LPM suspended state (LPM suspend bit = 1) and the software writes a zero to this bit, the device will generate a remote walk-up. Software can only write a zero to this bit when the LPM_REWP bit is set to 1. HW resets this bit when it receives a host initiated resume. HW only updates the LPM_SUS bit when the LPM_SUPP bit is equal to one.	0	RW
20	LPM_REWP		LPM Remote Wake-up Enabled by USB host.  HW sets this bit to one when the bRemoteWake bit in the LPM extended token is set to 1. HW will reset this bit to 0 when it receives the host initiated LPM resume, when a remote wake-up is sent by the device or when a USB bus reset is received. Software can use this bit to check if the remote wake-up feature is enabled by the host for the LPM transaction.	0	RO
23:21	-		Reserved.	0	RO
24	DCON_C		Device status - connect change.  The Connect Change bit is set when the device's pull-up resistor is disconnected because VBus disappeared. The bit is reset by writing a one to it.	0	RWC
25	DSUS_C		Device status - suspend change. The suspend change bit is set to 1 when the suspend bit toggles. The suspend bit can toggle because: - The device goes in the suspended state - The device is disconnected - The device receives resume signaling on its upstream port. The bit is reset by writing a one to it.	0	RWC
26	DRES_C		Device status - reset change.  This bit is set when the device received a bus reset. On a bus reset the device will automatically go to the default state (unconfigured and responding to address 0). The bit is reset by writing a one to it.	0	RWC

Bit	Symbol	Description	Reset value	Access
1:0	-	Reserved. Fixed to zero because the control endpoint zero is fixed to single-buffering for each physical endpoint.	0	R
9:2	BUF	Buffer in use: This register has one bit per physical endpoint. 0: HW is accessing buffer 0. 1: HW is accessing buffer 1.	0	R/W
31:10	-	Reserved	0	R

# 10.6.8 USB Endpoint Buffer Configuration (EPBUFCFG)

Table 159. USB Endpoint Buffer Configuration (EPBUFCFG, address 0x4008 001C) bit description

Bit	Symbol	Description	Reset value	Access
1:0	-	Reserved. Fixed to zero because the control endpoint zero is fixed to single-buffering for each physical endpoint.	0	R
9:2	BUF_SB	Buffer usage: This register has one bit per physical endpoint.  0: Single-buffer.  1: Double-buffer.  If the bit is set to single-buffer (0), it will not toggle the corresponding EPINUSE bit when it clears the active bit. If the bit is set to double-buffer (1), HW will toggle the EPINUSE bit when it clears the Active bit for the buffer.	0	R/W
31:10	-	Reserved	0	R

## Chapter 10: LPC1345/46/47 USB2.0 device controller

## 10.6.9 USB interrupt status register (INTSTAT)

Table 160. USB interrupt status register (INTSTAT, address 0x4008 0020) bit description

Bit	Symbol	Description	Reset value	Access
0	EP0OUT	Interrupt status register bit for the Control EP0 OUT direction.  This bit will be set if NBytes transitions to zero or the skip bit is set by software or a SETUP packet is successfully received for the control EP0.  If the IntOnNAK_CO is set, this bit will also be set when a NAK is transmitted for the Control EP0 OUT direction.  Software can clear this bit by writing a one to it.	0	R/WC
1	EPOIN	Interrupt status register bit for the Control EP0 IN direction. This bit will be set if NBytes transitions to zero or the skip bit is set by software. If the IntOnNAK_CI is set, this bit will also be set when a NAK is transmitted for the Control EP0 IN direction. Software can clear this bit by writing a one to it.	0	R/WC
2	EP1OUT	Interrupt status register bit for the EP1 OUT direction. This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AO is set, this bit will also be set when a NAK is transmitted for the EP1 OUT direction.  Software can clear this bit by writing a one to it.	0	R/WC
3	EP1IN	Interrupt status register bit for the EP1 IN direction. This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AI is set, this bit will also be set when a NAK is transmitted for the EP1 IN direction.  Software can clear this bit by writing a one to it.	0	R/WC
4	EP2OUT	Interrupt status register bit for the EP2 OUT direction.  This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AO is set, this bit will also be set when a NAK is transmitted for the EP2 OUT direction.  Software can clear this bit by writing a one to it.	0	R/WC
5	EP2IN	Interrupt status register bit for the EP2 IN direction. This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software. If the IntOnNAK_AI is set, this bit will also be set when a NAK is transmitted for the EP2 IN direction. Software can clear this bit by writing a one to it.	0	R/WC
6	EP3OUT	Interrupt status register bit for the EP3 OUT direction. This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AO is set, this bit will also be set when a NAK is transmitted for the EP3 OUT direction.  Software can clear this bit by writing a one to it.	0	R/WC

## Chapter 10: LPC1345/46/47 USB2.0 device controller

Table 160. USB interrupt status register (INTSTAT, address 0x4008 0020) bit description

Bit	Symbol	Description	Reset value	Access
7	EP3IN	Interrupt status register bit for the EP3 IN direction.  This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AI is set, this bit will also be set when a NAK is transmitted for the EP3 IN direction.  Software can clear this bit by writing a one to it.	0	R/WC
8	EP4OUT	Interrupt status register bit for the EP4 OUT direction.  This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AO is set, this bit will also be set when a NAK is transmitted for the EP4 OUT direction.  Software can clear this bit by writing a one to it.	0	R/WC
9	EP4IN	Interrupt status register bit for the EP4 IN direction.  This bit will be set if the corresponding Active bit is cleared by HW. This is done in case the programmed NBytes transitions to zero or the skip bit is set by software.  If the IntOnNAK_AI is set, this bit will also be set when a NAK is transmitted for the EP4 IN direction.  Software can clear this bit by writing a one to it.	0	R/WC
29:10	-	Reserved	0	RO
30	FRAME_INT	Frame interrupt. This bit is set to one every millisecond when the VbusDebounced bit and the DCON bit are set. This bit can be used by software when handling isochronous endpoints. Software can clear this bit by writing a one to it.	0	R/WC
31	DEV_INT	Device status interrupt. This bit is set by HW when one of the bits in the Device Status Change register are set. Software can clear this bit by writing a one to it.	0	R/WC

## 10.6.10 USB interrupt enable register (INTEN)

Table 161. USB interrupt enable register (INTEN, address 0x4008 0024) bit description

Bit	Symbol	Description	Reset value	Access
9:0	EP_INT_EN	If this bit is set and the corresponding USB interrupt status bit is set, a HW interrupt is generated on the interrupt line indicated by the corresponding USB interrupt routing bit.	0	R/W
29:10	-	Reserved	0	RO
30	FRAME_INT_EN	If this bit is set and the corresponding USB interrupt status bit is set, a HW interrupt is generated on the interrupt line indicated by the corresponding USB interrupt routing bit.	0	R/W
31	DEV_INT_EN	If this bit is set and the corresponding USB interrupt status bit is set, a HW interrupt is generated on the interrupt line indicated by the corresponding USB interrupt routing bit.	0	R/W

## Chapter 10: LPC1345/46/47 USB2.0 device controller

Table 165. Endpoint commands

	Endpoint commands						
Symbol	Access	Description					
Α	RW	Active					
		The buffer is enabled. HW can use the buffer to store received OUT data or to transmit data on the IN endpoint.					
		Software can only set this bit to '1'. As long as this bit is set to one, software is not allowed to update any of the values in this 32-bit word. In case software wants to deactivate the buffer, it must write a one to the corresponding "skip" bit in the USB Endpoint skip register. Hardware can only write this bit to zero. It will do this when it receives a short packet or when the NBytes field transitions to zero or when software has written a one to the "skip" bit.					
D	RW	Disabled					
		0: The selected endpoint is enabled.					
		1: The selected endpoint is disabled.					
		If a USB token is received for an endpoint that has the disabled bit set, hardware will ignore the token and not return any data or handshake. When a bus reset is received, software must set the disable bit of all endpoints to 1.					
		Software can only modify this bit when the active bit is zero.					
S	RW	Stall					
		0: The selected endpoint is not stalled					
		1: The selected endpoint is stalled					
		The Active bit has always higher priority than the Stall bit. This means that a Stall handshake is only sent when the active bit is zero and the stall bit is one.					
		Software can only modify this bit when the active bit is zero.					
TR	RW	Toggle Reset					
		When software sets this bit to one, the HW will set the toggle value equal to the value indicated in the "toggle value" (TV) bit.					
		For the control endpoint zero, this is not needed to be used because the hardware resets the endpoint toggle to one for both directions when a setup token is received.					
		For the other endpoints, the toggle can only be reset to zero when the endpoint is reset.					
RF/TV	RW	Rate Feedback mode / Toggle value					
		For bulk endpoints and isochronous endpoints this bit is reserved and must be set to zero.					
		For the control endpoint zero this bit is used as the toggle value. When the toggle reset bit is set, the data toggle is updated with the value programmed in this bit.					
		When the endpoint is used as an interrupt endpoint, it can be set to the following values.					
		0: Interrupt endpoint in 'toggle mode'					
		1: Interrupt endpoint in 'rate feedback mode'. This means that the data toggle is fixed to zero for all data packets.					
		When the interrupt endpoint is in 'rate feedback mode', the TR bit must always be set to zero.					

### Chapter 10: LPC1345/46/47 USB2.0 device controller

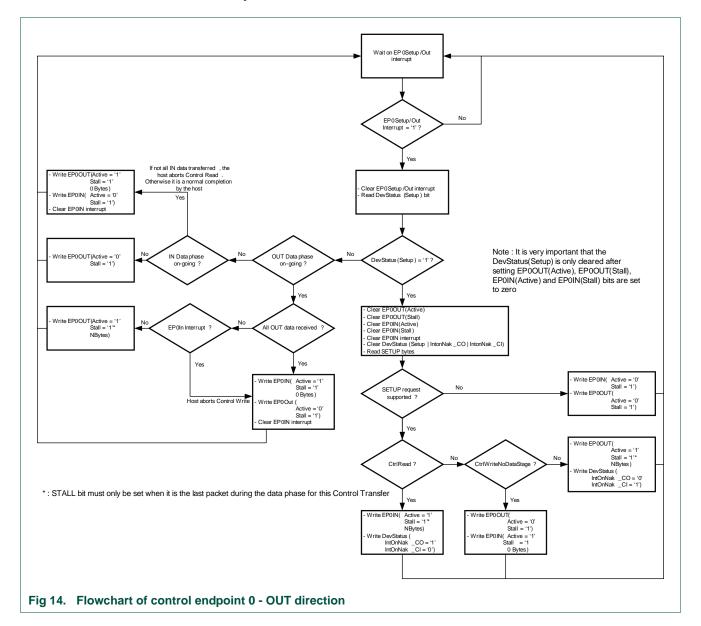

Table 165. Endpoint commands

Symbol	Access	Description
Т	RW	Endpoint Type
		0: Generic endpoint. The endpoint is configured as a bulk or interrupt endpoint
		1: Isochronous endpoint
NBytes	RW	For OUT endpoints this is the number of bytes that can be received in this buffer.
		For IN endpoints this is the number of bytes that must be transmitted.
		HW decrements this value with the packet size every time when a packet is successfully transferred.
		Note: If a short packet is received on an OUT endpoint, the active bit will be cleared and the NBytes value indicates the remaining buffer space that is not used. Software calculates the received number of bytes by subtracting the remaining NBytes from the programmed value.
Address	RW	Bits 21 to 6 of the buffer start address.
Offset		If the endpoint type is set to '0' (generic endpoint) this address is incremented every time a packet has been successfully received/transmitted.
		If the endpoint type is set to '1' (isochronous endpoint), the address is not incremented.

**Remark:** When receiving a SETUP token for endpoint zero, the HW will only read the SETUP bytes Buffer Address offset to know where it has to store the received SETUP bytes. The hardware will ignore all other fields. In case the SETUP stage contains more than 8 bytes, it will only write the first 8 bytes to memory. A USB compliant host must never send more than 8 bytes during the SETUP stage.

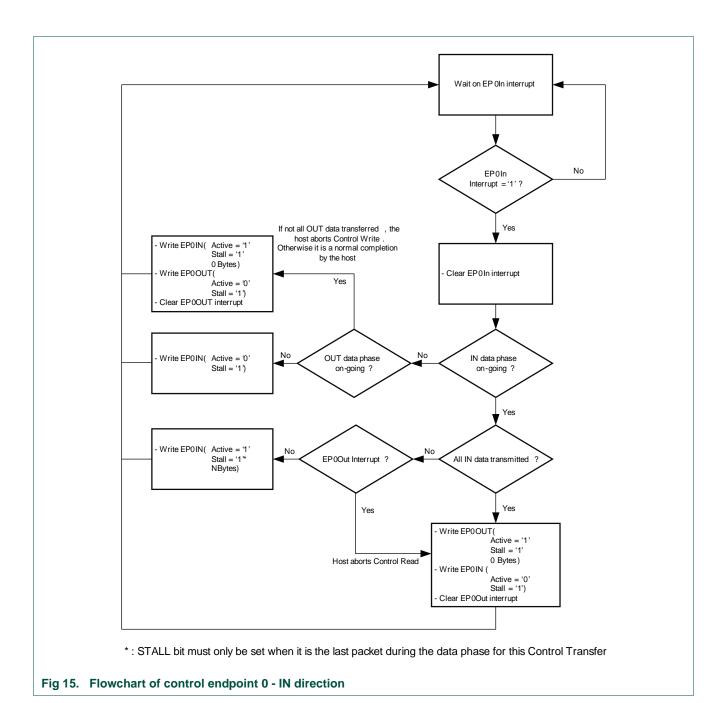

### Chapter 10: LPC1345/46/47 USB2.0 device controller

## 10.7.2 Control endpoint 0

151 of 416

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

## 10.7.3 Generic endpoint: single-buffering

To enable single-buffering, software must set the corresponding "USB EP Buffer Config" bit to zero. In the "USB EP Buffer in use" register, software can indicate which buffer is used in this case.

When software wants to transfer data, it programs the different bits in the Endpoint command/status entry and sets the active bits. The hardware will transmit/receive multiple packets for this endpoint until the NBytes value is equal to zero. When NBytes goes to zero, hardware clears the active bit and sets the corresponding interrupt status bit.

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

Software must wait until hardware has cleared the Active bit to change some of the command/status bits. This prevents hardware from overwriting a new value programmed by software with some old values that were still cached.

If software wants to disable the active bit before the hardware has finished handling the complete buffer, it can do this by setting the corresponding endpoint skip bit in USB endpoint skip register.

## 10.7.4 Generic endpoint: double-buffering

To enable double-buffering, software must set the corresponding "USB EP Buffer Config" bit to one. The "USB EP Buffer in use" register indicates which buffer will be used by HW when the next token is received.

When HW clears the active bit of the current buffer in use, it will switch the buffer in use. Software can also force HW to use a certain buffer by writing to the "USB EP Buffer in use" bit.

## 10.7.5 Special cases

#### 10.7.5.1 Use of the Active bit

The use of the Active bit is a bit different between OUT and IN endpoints.

When data must be received for the OUT endpoint, the software will set the Active bit to one and program the NBytes field to the maximum number of bytes it can receive.

When data must be transmitted for an IN endpoint, the software sets the Active bit to one and programs the NBytes field to the number of bytes that must be transmitted.

#### 10.7.5.2 Generation of a STALL handshake

Special care must be taken when programming the endpoint to send a STALL handshake. A STALL handshake is only sent in the following situations:

- The endpoint is enabled (Disabled bit = 0)
- The active bit of the endpoint is set to 0. (No packet needs to be received/transmitted for that endpoint).
- The stall bit of the endpoint is set to one.

### 10.7.5.3 Clear Feature (endpoint halt)

When a non-control endpoint has returned a STALL handshake, the host will send a Clear Feature (Endpoint Halt) for that endpoint. When the device receives this request, the endpoint must be unstalled and the toggle bit for that endpoint must be reset back to zero. In order to do that the software must program the following items for the endpoint that is indicated.

If the endpoint is used in single-buffer mode, program the following:

- Set STALL bit (S) to 0.
- Set toggle reset bit (TR) to 1 and set toggle value bit (TV) to 0.

If the endpoint is used in double-buffer mode, program the following:

#### Chapter 10: LPC1345/46/47 USB2.0 device controller

- Set the STALL bit of both buffer 0 and buffer 1 to 0.
- Read the buffer in use bit for this endpoint.
- Set the toggle reset bit (TR) to 1 and set the toggle value bit (TV) to 0 for the buffer indicated by the buffer in use bit.

## 10.7.5.4 Set configuration

When a SetConfiguration request is received with a configuration value different from zero, the device software must enable all endpoints that will be used in this configuration and reset all the toggle values. To do so, it must generate the procedure explained in Section 10.7.5.3 for every endpoint that will be used in this configuration.

For all endpoints that are not used in this configuration, it must set the Disabled bit (D) to one.

## 10.7.6 **USB** wake-up

### 10.7.6.1 Waking up from Deep-sleep and Power-down modes on USB activity

To allow the LPC1315/16/17/45/46/47 to wake up from Deep-sleep or Power-down mode on USB activity, complete the following steps:

- 1. Set bit AP\_CLK in the USBCLKCTRL register (<u>Table 36</u>) to 0 (default) to enable automatic control of the USB need\_clock signal.
- 2. Wait until USB activity is suspended by polling the DSUS bit in the DSVCMD\_STAT register (DSUS = 1).
- 3. The USB need\_clock signal will be deasserted after another 2 ms. Poll the USBCLKST register until the USB need\_clock status bit is 0 (<u>Table 37</u>).
- 4. Once the USBCLKST register returns 0, enable the USB activity wake-up interrupt in the NVIC (# 30) and clear it.
- 5. Set bit 1 in the USBCLKCTRL register to 1 to trigger the USB activity wake-up interrupt on the rising edge of the USB need clock signal.
- 6. Enable the wake-up from Deep-sleep or Power-down modes on this interrupt by enabling the USB need\_clock signal in the STARTERP1 register (<u>Table 39</u>, bit 19).
- 7. Enter Deep-sleep or Power-down modes by writing to the PCON register.
- 8. Execute a WFI instruction.

The LPC1315/16/17/45/46/47 will automatically wake up and resume execution on USB activity.

### 10.7.6.2 Remote wake-up

To issue a remote wake-up when the USB activity is suspended, complete the following steps:

- Set bit AP\_CLK in the USBCLKCTRL register to 0 (<u>Table 36</u>, default) to enable automatic control of the USB need\_clock signal.
- When it is time to issue a remote wake-up, turn on the USB clock and enable the USB clock source.
- Force the USB clock on by writing a 1 to bit AP\_CLK (<u>Table 36</u>, bit 0) in the USBCLKCTRL register.

UM10524

## Chapter 10: LPC1345/46/47 USB2.0 device controller

- 4. Write a 0 to the DSUS bit in the DSVCMD\_STAT register.
- 5. Wait until the USB leaves the suspend state by polling the DSUS bit in the DSVCMD\_STAT register (DSUS =0).
- 6. Clear the AP\_CLK bit (<u>Table 36</u>, bit 0) in the USBCLKCTRL to enable automatic USB clock control.

# UM10524

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Rev. 4 — 12 March 2013

**User manual** 

## 11.1 How to read this chapter

The USB on-chip drivers are available on parts LPC1345/46/47.

## 11.2 Introduction

The boot ROM contains a USB driver to simplify the USB application development. The USB driver implements the Communication Device Class (CDC), the Human Interface Device (HID), and the Mass Storage Device (MSC) device class. The USB on-chip drivers support composite device.

## 11.3 USB driver functions

The USB device driver ROM API consists of the following modules:

- Communication Device Class (CDC) function driver. This module contains an internal
  implementation of the USB CDC Class. User applications can use this class driver
  instead of implementing the CDC-ACM class manually via the low-level USBD\_HW
  and USBD\_Core APIs. This module is designed to simplify the user code by exposing
  only the required interface needed to interface with Devices using the USB CDC-ACM
  Class.
  - Communication Device Class function driver initialization parameter data structure (Table 193 "USBD\_CDC\_INIT\_PARAM class structure").
  - CDC class API functions structure. This module exposes functions which interact directly with USB device controller hardware (<u>Table 192 "USBD\_CDC\_API class</u> <u>structure"</u>).
- USB core layer
  - struct (Table 189 "\_WB\_T class structure")
  - union (Table 166 "\_\_WORD\_BYTE class structure")
  - struct (Table 167 "\_BM\_T class structure")
  - struct (Table 180 "\_REQUEST\_TYPE class structure")
  - struct (Table 187 "\_USB\_SETUP\_PACKET class structure")
  - struct (Table 183 "\_USB\_DEVICE\_QUALIFIER\_DESCRIPTOR class structure")
  - struct USB device descriptor
  - struct (Table 183 "\_USB\_DEVICE\_QUALIFIER\_DESCRIPTOR class structure")
  - struct USB configuration descriptor
  - struct (Table 185 "\_USB\_INTERFACE\_DESCRIPTOR class structure")
  - struct USB endpoint descriptor
  - struct (Table 188 "\_USB\_STRING\_DESCRIPTOR class structure")
  - struct (Table 181 "\_USB\_COMMON\_DESCRIPTOR class structure")
  - struct (Table 186 "\_USB\_OTHER\_SPEED\_CONFIGURATION class structure")

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

- USB descriptors data structure (<u>Table 182 "\_USB\_CORE\_DESCS\_T class structure</u>")
- USB device stack initialization parameter data structure (<u>Table 191</u> "USBD API INIT PARAM class structure").
- USB device stack core API functions structure (<u>Table 194 "USBD\_CORE\_API</u> class structure").
- Device Firmware Upgrade (DFU) class function driver
  - DFU descriptors data structure (<u>Table 196 "USBD\_DFU\_INIT\_PARAM class</u> structure").
  - DFU class API functions structure. This module exposes functions which interact directly with the USB device controller hardware (<u>Table 195 "USBD\_DFU\_API</u> <u>class structure</u>").
- HID class function driver
  - struct (Table 175 "\_HID\_DESCRIPTOR class structure").
  - struct (Table 177 "\_HID\_REPORT\_T class structure").
  - USB descriptors data structure (<u>Table 198 "USBD\_HID\_INIT\_PARAM class structure</u>").
  - HID class API functions structure. This structure contains pointers to all the functions exposed by the HID function driver module (<u>Table 199 "USBD\_HW\_API</u> <u>class structure"</u>).
- USB device controller driver
  - Hardware API functions structure. This module exposes functions which interact directly with the USB device controller hardware (<u>Table 199 "USBD\_HW\_API class</u> structure").
- Mass Storage Class (MSC) function driver
  - Mass Storage Class function driver initialization parameter data structure (<u>Table 201</u>).
  - MSC class API functions structure. This module exposes functions which interact directly with the USB device controller hardware (Table 200).

## 11.4 Calling the USB device driver

A fixed location in ROM contains a pointer to the ROM driver table i.e. 0x1FFF 1FF8. The ROM driver table contains a pointer to the USB driver table. Pointers to the various USB driver functions are stored in this table. USB driver functions can be called by using a C structure. Figure 16 illustrates the pointer mechanism used to access the on-chip USB driver.

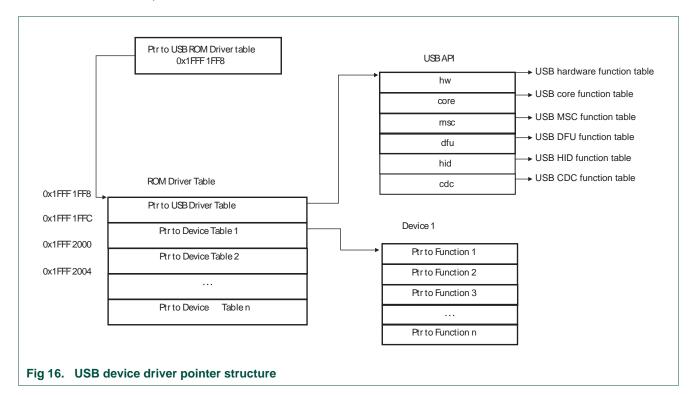

```
typedef struct USBD_API
{
const USBD_HW_API_T* hw;
const USBD_CORE_API_T* core;
const USBD_MSC_API_T* msc;
```

## 11.5.10 \_HID\_DESCRIPTOR

HID class-specific HID Descriptor.

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 175. \_HID\_DESCRIPTOR class structure

Description
uint8_tuint8_t _HID_DESCRIPTOR::bLength
Size of the descriptor, in bytes.
uint8_tuint8_t _HID_DESCRIPTOR::bDescriptorType
Type of HID descriptor.
uint16_tuint16_t _HID_DESCRIPTOR::bcdHID
BCD encoded version that the HID descriptor and device complies to.
uint8_tuint8_t _HID_DESCRIPTOR::bCountryCode
Country code of the localized device, or zero if universal.
uint8_tuint8_t _HID_DESCRIPTOR::bNumDescriptors
Total number of HID report descriptors for the interface.
PRE_PACK struct POST_PACK _HID_DESCRIPTOR::_HID_DESCRIPTOR_LISTPRE_PACK struct
POST_PACK _HID_DESCRIPTOR::_HID_DESCRIPTOR_LIST
_HID_DESCRIPTOR::DescriptorList[1][1]
Array of one or more descriptors

## 11.5.11 \_HID\_DESCRIPTOR::\_HID\_DESCRIPTOR\_LIST

Table 176. \_HID\_DESCRIPTOR::\_HID\_DESCRIPTOR\_LIST class structure

Member	Description
bDescriptorType	uint8_tuint8_t _HID_DESCRIPTOR::_HID_DESCRIPTOR_LIST::bDescriptorType Type of HID report.
wDescriptorLength	uint16_tuint16_t _HID_DESCRIPTOR::_HID_DESCRIPTOR_LIST::wDescriptorLength  Length of the associated HID report descriptor, in bytes.

## 11.5.12 \_HID\_REPORT\_T

HID report descriptor data structure.

Table 177. \_HID\_REPORT\_T class structure

Member	Description
len	uint16_tuint16_t _HID_REPORT_T::len
	Size of the report descriptor in bytes.
idle_time	uint8_tuint8_t _HID_REPORT_T::idle_time
	This value is used by stack to respond to Set_Idle & GET_Idle requests for the specified report ID. The value of this field specified the rate at which duplicate reports are generated for the specified Report ID. For example, a device with two input reports could specify an idle rate of 20 milliseconds for report ID 1 and 500 milliseconds for report ID 2.
pad	uint8_tuint8_t _HID_REPORT_T::pad
	Padding space.
desc	uint8_t *uint8_t* _HID_REPORT_T::desc
	Report descriptor.

## 11.5.17 \_USB\_CORE\_DESCS\_T

USB descriptors data structure.

Table 182. \_USB\_CORE\_DESCS\_T class structure

Member	Description
device_desc	uint8_t *uint8_t* _USB_CORE_DESCS_T::device_desc
	Pointer to USB device descriptor
string_desc	uint8_t *uint8_t* _USB_CORE_DESCS_T::string_desc
	Pointer to array of USB string descriptors
full_speed_desc	uint8_t *uint8_t* _USB_CORE_DESCS_T::full_speed_desc
	Pointer to USB device configuration descriptor when device is operating in full speed mode.
high_speed_desc	uint8_t *uint8_t* _USB_CORE_DESCS_T::high_speed_desc
	Pointer to USB device configuration descriptor when device is operating in high speed mode. For full-speed only implementation this pointer should be same as full_speed_desc.
device_qualifier	uint8_t *uint8_t* _USB_CORE_DESCS_T::device_qualifier
	Pointer to USB device qualifier descriptor. For full-speed only implementation this pointer should be set to null (0).

## 11.5.18 \_USB\_DEVICE\_QUALIFIER\_DESCRIPTOR

Table 183. \_USB\_DEVICE\_QUALIFIER\_DESCRIPTOR class structure

Member	Description
bLength	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bLength
	Size of descriptor
bDescriptorType	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bDescriptorType
	Device Qualifier Type
bcdUSB	uint16_tuint16_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bcdUSB
	USB specification version number (e.g., 0200H for V2.00)
bDeviceClass	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bDeviceClass
	Class Code
bDeviceSubClass	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bDeviceSubClass
	SubClass Code
bDeviceProtocol	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bDeviceProtocol
	Protocol Code
bMaxPacketSize0	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bMaxPacketSize0
	Maximum packet size for other speed
bNumConfigurations	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bNumConfigurations
	Number of Other-speed Configurations
bReserved	uint8_tuint8_t _USB_DEVICE_QUALIFIER_DESCRIPTOR::bReserved
	Reserved for future use, must be zero

## 11.5.19 \_USB\_DFU\_FUNC\_DESCRIPTOR

UM10524

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 184. \_USB\_DFU\_FUNC\_DESCRIPTOR class structure

Member	Description
bLength	uint8_tuint8_t _USB_DFU_FUNC_DESCRIPTOR::bLength
bDescriptorType	uint8_tuint8_t _USB_DFU_FUNC_DESCRIPTOR::bDescriptorType
bmAttributes	uint8_tuint8_t _USB_DFU_FUNC_DESCRIPTOR::bmAttributes
wDetachTimeOut	uint16_tuint16_t _USB_DFU_FUNC_DESCRIPTOR::wDetachTimeOut
wTransferSize	uint16_tuint16_t _USB_DFU_FUNC_DESCRIPTOR::wTransferSize
bcdDFUVersion	uint16_tuint16_t _USB_DFU_FUNC_DESCRIPTOR::bcdDFUVersion

## 11.5.20 \_USB\_INTERFACE\_DESCRIPTOR

#### Table 185. USB INTERFACE DESCRIPTOR class structure

Member	Description
bLength	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bLength
	Size of this descriptor in bytes
bDescriptorType	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bDescriptorType
	INTERFACE Descriptor Type
bInterfaceNumber	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bInterfaceNumber
	Number of this interface. Zero-based value identifying the index in the array of concurrent interfaces supported by this configuration.
bAlternateSetting	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bAlternateSetting
	Value used to select this alternate setting for the interface identified in the prior field
bNumEndpoints	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bNumEndpoints
	Number of endpoints used by this interface (excluding endpoint zero). If this value is zero, this interface only uses the Default Control Pipe.
bInterfaceClass	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bInterfaceClass
	Class code (assigned by the USB-IF).
bInterfaceSubClass	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bInterfaceSubClass
	Subclass code (assigned by the USB-IF).
bInterfaceProtocol	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::bInterfaceProtocol
	Protocol code (assigned by the USB).
iInterface	uint8_tuint8_t _USB_INTERFACE_DESCRIPTOR::iInterface
	Index of string descriptor describing this interface

## 11.5.21 \_USB\_OTHER\_SPEED\_CONFIGURATION

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 186. \_USB\_OTHER\_SPEED\_CONFIGURATION class structure

Member	Description
bLength	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bLength
	Size of descriptor
bDescriptorType	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bDescriptorType
	Other_speed_Configuration Type
wTotalLength	uint16_tuint16_t _USB_OTHER_SPEED_CONFIGURATION::wTotalLength
	Total length of data returned
bNumInterfaces	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bNumInterfaces
	Number of interfaces supported by this speed configuration
bConfigurationValue	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bConfigurationValue
	Value to use to select configuration
IConfiguration	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::IConfiguration
	Index of string descriptor
bmAttributes	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bmAttributes
	Same as Configuration descriptor
bMaxPower	uint8_tuint8_t _USB_OTHER_SPEED_CONFIGURATION::bMaxPower
	Same as Configuration descriptor

## 11.5.22 \_USB\_SETUP\_PACKET

Table 187. \_USB\_SETUP\_PACKET class structure

Description
REQUEST_TYPEREQUEST_TYPE _USB_SETUP_PACKET::bmRequestType
This bit-mapped field identifies the characteristics of the specific requestBM_T.
uint8_tuint8_t _USB_SETUP_PACKET::bRequest
This field specifies the particular request. The Type bits in the bmRequestType field modify the meaning of this field.
USBD_REQUEST.
WORD_BYTEWORD_BYTE _USB_SETUP_PACKET::wValue
Used to pass a parameter to the device, specific to the request.
WORD_BYTEWORD_BYTE _USB_SETUP_PACKET::wIndex
Used to pass a parameter to the device, specific to the request. The wIndex field is often used in requests to specify an endpoint or an interface.
uint16_tuint16_t _USB_SETUP_PACKET::wLength
This field specifies the length of the data transferred during the second phase of the control transfer.

## 11.5.23 \_USB\_STRING\_DESCRIPTOR

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 188. \_USB\_STRING\_DESCRIPTOR class structure

Member	Description
bLength	uint8_tuint8_t _USB_STRING_DESCRIPTOR::bLength
	Size of this descriptor in bytes
bDescriptorType	uint8_tuint8_t _USB_STRING_DESCRIPTOR::bDescriptorType
	STRING Descriptor Type
bString	uint16_tuint16_t _USB_STRING_DESCRIPTOR::bString
	UNICODE encoded string

## 11.5.24 WB T

### Table 189. \_WB\_T class structure

Member	Description
L	uint8_tuint8_t _WB_T::L
	lower byte
Н	uint8_tuint8_t _WB_T::H
	upper byte

## 11.5.25 USBD\_API

Main USBD API functions structure. This structure contains pointer to various USB Device stack's sub-module function tables. This structure is used as main entry point to access various methods (grouped in sub-modules) exposed by ROM based USB device stack.

### Table 190. USBD\_API class structure

Member	Description
hw	const USBD_HW_API_T *const USBD_HW_API_T* USBD_API::hw
	Pointer to function table which exposes functions which interact directly with USB device stack's core layer.
core	const USBD_CORE_API_T *const USBD_CORE_API_T* USBD_API::core
	Pointer to function table which exposes functions which interact directly with USB device controller hardware.
msc	const USBD_MSC_API_T *const USBD_MSC_API_T* USBD_API::msc
	Pointer to function table which exposes functions provided by MSC function driver module.
dfu	const USBD_DFU_API_T *const USBD_DFU_API_T* USBD_API::dfu
	Pointer to function table which exposes functions provided by DFU function driver module.
hid	const USBD_HID_API_T *const USBD_HID_API_T* USBD_API::hid
	Pointer to function table which exposes functions provided by HID function driver module.

166 of 416

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 190. USBD\_API class structure

Member	Description
cdc	const USBD_CDC_API_T *const USBD_CDC_API_T* USBD_API::cdc  Pointer to function table which exposes functions provided by CDC-ACM function driver module.
reserved6	const uint32_t *const uint32_t* USBD_API::reserved6  Reserved for future function driver module.
version	const uint32_tconst uint32_t USBD_API::version  Version identifier of USB ROM stack. The version is defined as 0x0CHDMhCC where each nibble represents version number of the corresponding component. CC - 7:0 - 8bit core version number h - 11:8 - 4bit hardware interface version number M - 15:12 - 4bit MSC class module version number D - 19:16 - 4bit DFU class module version number H - 23:20 - 4bit HID class module version number C - 27:24 - 4bit CDC class module version number H - 31:28 - 4bit reserved

## 11.5.26 USBD\_API\_INIT\_PARAM

USB device stack initialization parameter data structure.

Table 191. USBD\_API\_INIT\_PARAM class structure

Member	Description
usb_reg_base	uint32_tuint32_t USBD_API_INIT_PARAM::usb_reg_base
	USB device controller's base register address.
mem_base	uint32_tuint32_t USBD_API_INIT_PARAM::mem_base
	Base memory location from where the stack can allocate data and buffers.
	<b>Remark:</b> The memory address set in this field should be accessible by USB DMA controller. Also this value should be aligned on 2048 byte boundary.
mem_size	uint32_tuint32_t USBD_API_INIT_PARAM::mem_size
	The size of memory buffer which stack can use.
	<b>Remark:</b> The mem_size should be greater than the size returned by USBD_HW_API::GetMemSize() routine.
max_num_ep	uint8_tuint8_t USBD_API_INIT_PARAM::max_num_ep
	max number of endpoints supported by the USB device controller instance (specified by
pad0	uint8_tuint8_t USBD_API_INIT_PARAM::pad0[3][3]
USB_Reset_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Reset_Event
	Event for USB interface reset. This event fires when the USB host requests that the device reset its interface. This event fires after the control endpoint has been automatically configured by the library.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will prevent the device from enumerating correctly or operate properly.
USB_Suspend_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Suspend_Event
	Event for USB suspend. This event fires when the USB host suspends the device by halting its transmission of Start Of Frame pulses to the device. This is generally hooked in order to move the device over to a low power state until the host wakes up the device.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will cause other system issues.

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 191, USBD API INIT PARAM class structure

Member	Description
USB_Resume_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Resume_Event
	Event for USB wake up or resume. This event fires when a the USB device interface is suspended and the host wakes up the device by supplying Start Of Frame pulses. This is generally hooked to pull the user application out of a low power state and back into normal operating mode.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will cause other system issues.
reserved_sbz	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::reserved_sbz
	Reserved parameter should be set to zero.
USB_SOF_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_SOF_Event
	Event for USB Start Of Frame detection, when enabled. This event fires at the start of each USB frame, once per millisecond in full-speed mode or once per 125 microseconds in high-speed mode, and is synchronized to the USB bus.
	This event is time-critical; it is run once per millisecond (full-speed mode) and thus long handlers will significantly degrade device performance. This event should only be enabled when needed to reduce device wake-ups.
	This event is not normally active - it must be manually enabled and disabled via the USB interrupt register.
	<b>Remark:</b> This event is not normally active - it must be manually enabled and disabled via the USB interrupt register.
USB_WakeUpCfg	USB_PARAM_CB_TUSB_PARAM_CB_T USBD_API_INIT_PARAM::USB_WakeUpCfg
	Event for remote wake-up configuration, when enabled. This event fires when the USB host request the device to configure itself for remote wake-up capability. The USB host sends this request to device which report remote wake-up capable in their device descriptors, before going to low-power state. The application layer should implement this callback if they have any special on board circuit to triger remote wake up event. Also application can use this callback to differentiate the following SUSPEND event is caused by cable plug-out or host SUSPEND request. The device can wake-up host only after receiving this callback and remote wake-up feature is enabled by host. To signal remote wake-up the device has to generate resume signaling on bus by calling usapi.hw->WakeUp() routine.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. param1 = When 0 - Clear the wake-up configuration, 1 - Enable the wake-up configuration.
	Returns:
	The call back should return ErrorCode_t type to indicate success or error condition.
USB_Power_Event	USB_PARAM_CB_TUSB_PARAM_CB_T
	Reserved parameter should be set to zero.
USB_Error_Event	USB_PARAM_CB_TUSB_PARAM_CB_T USBD_API_INIT_PARAM:USB_Error_Event
	Event for error condition. This event fires when USB device controller detect an error condition in the system.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	param1 = USB device interrupt status register.  Returns:

## Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 191. USBD\_API\_INIT\_PARAM class structure

Member	Description
USB_Configure_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Configure_Event
	Event for USB configuration number changed. This event fires when a the USB host changes the selected configuration number. On receiving configuration change request from host, the stack enables/configures the endpoints needed by the new configuration before calling this callback function.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will prevent the device from enumerating correctly or operate properly.
USB_Interface_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Interface_Event
	Event for USB interface setting changed. This event fires when a the USB host changes the interface setting to one of alternate interface settings. On receiving interface change request from host, the stack enables/configures the endpoints needed by the new alternate interface setting before calling this callback function.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will prevent the device from enumerating correctly or operate properly.
USB_Feature_Event	USB_CB_TUSB_CB_T USBD_API_INIT_PARAM::USB_Feature_Event
	Event for USB feature changed. This event fires when a the USB host send set/clear feature request. The stack handles this request for USB_FEATURE_REMOTE_WAKEUP, USB_FEATURE_TEST_MODE and USB_FEATURE_ENDPOINT_STALL features only. On receiving feature request from host, the stack handle the request appropriately and then calls this callback function.
	<b>Remark:</b> This event is called from USB_ISR context and hence is time-critical. Having delays in this callback will prevent the device from enumerating correctly or operate properly.
virt_to_phys	uint32_t(*uint32_t(* USBD_API_INIT_PARAM::virt_to_phys)(void *vaddr))(void *vaddr)
	Reserved parameter for future use. should be set to zero.
cache_flush	<pre>void(*void(* USBD_API_INIT_PARAM::cache_flush)(uint32_t *start_adr, uint32_t</pre>
	Reserved parameter for future use. should be set to zero.

## 11.5.27 USBD\_CDC\_API

CDC class API functions structure. This module exposes functions which interact directly with USB device controller hardware.

Table 192. USBD\_CDC\_API class structure

Member	Description
GetMemSize	uint32_t(*uint32_t USBD_CDC_API::GetMemSize)(USBD_CDC_INIT_PARAM_T *param)
	Function to determine the memory required by the CDC function driver module.
	This function is called by application layer before calling pUsbApi->CDC->Init(), to allocate memory used by CDC function driver module. The application should allocate the memory which is accessible by USB controller/DMA controller.
	Remark: Some memory areas are not accessible by all bus masters.
	Parameters:
	<ol> <li>param = Structure containing CDC function driver module initialization parameters.</li> </ol>
	Returns:
	Returns the required memory size in bytes.

## Chapter 11: LPC1345/46/47 USB on-chip drivers

### Table 192. USBD\_CDC\_API class structure

Member	Description
init	<pre>ErrorCode_t(*ErrorCode_t USBD_CDC_API::init)(USBD_HANDLE_T hUsb, USBD_CDC_INIT_PARAM_T     *param, USBD_HANDLE_T *phCDC)</pre>
	Function to initialize CDC function driver module.
	This function is called by application layer to initialize CDC function driver module.
	hUsbHandle to the USB device stack. paramStructure containing CDC function driver module initialization parameters.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. param = Structure containing CDC function driver module initialization parameters.
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success
	<ol><li>ERR_USBD_BAD_MEM_BUF = Memory buffer passed is not 4-byte aligned or smaller than required.</li></ol>
	<ol><li>ERR_API_INVALID_PARAM2 = Either CDC_Write() or CDC_Read() or CDC_Verify() callbacks are not defined.</li></ol>
	<ol><li>ERR_USBD_BAD_INTF_DESC = Wrong interface descriptor is passed.</li></ol>
	<ol><li>ERR_USBD_BAD_EP_DESC = Wrong endpoint descriptor is passed.</li></ol>
SendNotification	<pre>ErrorCode_t(*ErrorCode_t USBD_CDC_API::SendNotification)(USBD_HANDLE_T hCdc, uint8_t bNotification, uint16_t data)</pre>
	Function to send CDC class notifications to host.
	This function is called by application layer to send CDC class notifications to host.
	Remark: The current version of the driver only supports following notifications allowed by ACM subclass: CDC_NOTIFICATION_NETWORK_CONNECTION, CDC_RESPONSE_AVAILABLE, CDC_NOTIFICATION_SERIAL_STATE. For all other notifications application should construct the notification buffer appropriately and call hw->USB_WriteEP() for interrupt endpoint associated with the interface.
	Parameters:
	1. hCdc = Handle to CDC function driver.
	<ol> <li>bNotification = Notification type allowed by ACM subclass. Should be CDC_NOTIFICATION_NETWORK_CONNECTION, CDC_RESPONSE_AVAILABLE or CDC_NOTIFICATION_SERIAL_STATE. For all other types ERR_API_INVALID_PARAM2 is returned. See <tbd></tbd></li> </ol>
	<ol> <li>data = Data associated with notification. For CDC_NOTIFICATION_NETWORK_CONNECTION a non-zero data value is interpreted as connected state. For CDC_RESPONSE_AVAILABLE this parameter is ignored. For CDC_NOTIFICATION_SERIAL_STATE the data should use bitmap values defined in <tbd></tbd></li> </ol>
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success
	<ol><li>ERR_API_INVALID_PARAM2 = If unsupported notification type is passed.</li></ol>

## 11.5.28 USBD\_CDC\_INIT\_PARAM

Communication Device Class function driver initialization parameter data structure.

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 193. USBD\_CDC\_INIT\_PARAM class structure

Member	Description
mem_base	uint32_tuint32_t USBD_CDC_INIT_PARAM::mem_base
	Base memory location from where the stack can allocate data and buffers.
	<b>Remark:</b> The memory address set in this field should be accessible by USB DMA controller. Also this value should be aligned on 4 byte boundary.
mem_size	uint32_tuint32_t USBD_CDC_INIT_PARAM::mem_size
	The size of memory buffer which stack can use.
	<b>Remark:</b> The mem_size should be greater than the size returned by USBD_CDC_API::GetMemSize() routine.
cif_intf_desc	uint8_t *uint8_t* USBD_CDC_INIT_PARAM::cif_intf_desc
	Pointer to the control interface descriptor within the descriptor array (
dif_intf_desc	uint8_t *uint8_t* USBD_CDC_INIT_PARAM::dif_intf_desc
	Pointer to the data interface descriptor within the descriptor array (
CIC_GetRequest	ErrorCode_t(*ErrorCode_t(* USBD_CDC_INIT_PARAM::CIC_GetRequest)(USBD_HANDLE_T hHid, USB_SETUP_PACKET *pSetup, uint8_t **pBuffer, uint16_t *length))(USBD_HANDLE_T hHid, USB_SETUP_PACKET *pSetup, uint8_t **pBuffer, uint16_t *length)  Communication Interface Class specific get request call back function

Communication Interface Class specific get request call-back function.

This function is provided by the application software. This function gets called when host sends CIC management element get requests.

Remark: Applications implementing Abstract Control Model subclass can set this param to NULL. As the default driver parses ACM requests and calls the individual ACM call-back routines defined in this structure. For all other subclasses this routine should be provided by the application. The setup packet data (pSetup) is passed to the call-back so that application can extract the CIC request type and other associated data. By default the stack will assign pBuffer pointer to EP0Buff allocated at init. The application code can directly write data into this buffer as long as data is less than 64 byte. If more data has to be sent then application code should update pBuffer pointer and length accordingly.

#### Parameters:

- 1. hCdc = Handle to CDC function driver.
- 2. pSetup = Pointer to setup packet received from host.
- pBuffer = Pointer to a pointer of data buffer containing request data. Pointer-to-pointer is used to implement zero-copy buffers. See USBD\_ZeroCopy for more details on zero-copy concept.
- 4. length = Amount of data to be sent back to host.

#### Returns

The call back should returns ErrorCode\_t type to indicate success or error condition.

#### Return values:

- 1. LPC\_OK = On success.
- 2. ERR\_USBD\_UNHANDLED = Event is not handled hence pass the event to next in line.
- 3. ERR\_USBD\_xxx = For other error conditions.

#### Member

#### Description

CIC\_SetRequest

Communication Interface Class specific set request call-back function.

This function is provided by the application software. This function gets called when host sends a CIC management element requests.

Remark: Applications implementing Abstract Control Model subclass can set this param to NULL. As the default driver parses ACM requests and calls the individual ACM call-back routines defined in this structure. For all other subclasses this routine should be provided by the application. The setup packet data (pSetup) is passed to the call-back so that application can extract the CIC request type and other associated data. If a set request has data associated, then this call-back is called twice. (1) First when setup request is received, at this time application code could update pBuffer pointer to point to the intended destination. The length param is set to 0 so that application code knows this is first time. By default the stack will assign pBuffer pointer to EP0Buff allocated at init. Note, if data length is greater than 64 bytes and application code doesn't update pBuffer pointer the stack will send STALL condition to host. (2) Second when the data is received from the host. This time the length param is set with number of data bytes received.

#### Parameters:

- 1. hCdc = Handle to CDC function driver.
- 2. pSetup = Pointer to setup packet received from host.
- pBuffer = Pointer to a pointer of data buffer containing request data. Pointer-to-pointer is used to implement zero-copy buffers. See USBD\_ZeroCopy for more details on zero-copy concept.
- 4. length = Amount of data copied to destination buffer.

#### Returns:

The call back should returns ErrorCode\_t type to indicate success or error condition.

### Return values:

- 1. LPC OK = On success.
- 2. ERR\_USBD\_UNHANDLED = Event is not handled hence pass the event to next in line.
- 3. ERR\_USBD\_xxx = For other error conditions.

	3. ERR_USBD_xxx = For other error conditions.

## 11.5.29 USBD\_CORE\_API

USBD stack Core API functions structure.

Member	Description
RegisterClassHandler	<pre>ErrorCode_t(*ErrorCode_t USBD_CORE_API::RegisterClassHandler)(USBD_HANDLE_T hUsb,</pre>
	Function to register class specific EP0 event handler with USB device stack.
	The application layer uses this function when it has to register the custom class's EP0 handler. The stack calls all the registered class handlers on any EP0 event before going through default handling of the event. This gives the class handlers to implement class specific request handlers and also to override the default stack handling for a particular event targeted to the interface. Check USB_EP_HANDLER_T for more details on how the callback function should be implemented. Also application layer could use this function to register EP0 handler which responds to vendor specific requests.
	hUsbHandle to the USB device stack. pfnClass specific EP0 handler function. dataPointer to the data which will be passed when callback function is called by the stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. pfn = Class specific EP0 handler function.
	3. data = Pointer to the data which will be passed when callback function is called by the stack.
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success
	<ol><li>ERR_USBD_TOO_MANY_CLASS_HDLR(0x0004000c) = The number of class handlers registered is greater than the number of handlers allowed by the stack.</li></ol>

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 194. USBD\_CORE\_API class structure

### Member

#### Description

#### RegisterEpHandler

Function to register interrupt/event handler for the requested endpoint with USB device stack.

The application layer uses this function to register the custom class's EP0 handler. The stack calls all the registered class handlers on any EP0 event before going through default handling of the event. This gives the class handlers to implement class specific request handlers and also to override the default stack handling for a particular event targeted to the interface. Check USB\_EP\_HANDLER\_T for more details on how the callback function should be implemented.

hUsbHandle to the USB device stack. ep\_indexClass specific EP0 handler function. pfnClass specific EP0 handler function. dataPointer to the data which will be passed when callback function is called by the stack.

#### Parameters:

- 1. hUsb = Handle to the USB device stack.
- 2. ep\_index = Class specific EP0 handler function.
- 3. pfn = Class specific EP0 handler function.
- 4. data = Pointer to the data which will be passed when callback function is called by the stack.

#### Returns

Returns ErrorCode\_t type to indicate success or error condition.

#### Return values:

- 1. LPC OK = On success
- 2. ERR\_USBD\_TOO\_MANY\_CLASS\_HDLR(0x0004000c) = Too many endpoint handlers.

#### SetupStage

void(\*void USBD\_CORE\_API::SetupStage)(USBD\_HANDLE\_T hUsb)

Function to set EP0 state machine in setup state.

This function is called by USB stack and the application layer to set the EP0 state machine in setup state. This function will read the setup packet received from USB host into stack's buffer.

**Remark:** This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.

#### Parameters:

1. hUsb = Handle to the USB device stack.

#### Returns:

### Nothing.

### DataInStage

void(\*void USBD\_CORE\_API::DataInStage)(USBD\_HANDLE\_T hUsb)

Function to set EP0 state machine in data in state.

This function is called by USB stack and the application layer to set the EP0 state machine in data\_in state. This function will write the data present in EP0Data buffer to EP0 FIFO for transmission to host.

**Remark:** This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.

### Parameters:

1. hUsb = Handle to the USB device stack.

#### Returns:

Nothing.

**UM10524 NXP Semiconductors** 

### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 194. USBD\_CORE\_API class structure

Member	Description
DataOutStage	<pre>void(*void USBD_CORE_API::DataOutStage)(USBD_HANDLE_T hUsb)</pre>
	Function to set EP0 state machine in data_out state.
	This function is called by USB stack and the application layer to set the EP0 state machine in data_out state. This function will read the control data (EP0 out packets) received from USB host into EP0Data buffer.
	<b>Remark:</b> This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	Returns:
	Nothing.
StatusInStage	<pre>void(*void USBD_CORE_API::StatusInStage)(USBD_HANDLE_T hUsb)</pre>
	Function to set EP0 state machine in status_in state.
	This function is called by USB stack and the application layer to set the EP0 state machine in status_in state. This function will send zero length IN packet on EP0 to host, indicating positive status.
	<b>Remark:</b> This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	Returns:
	Nothing.
StatusOutStage	<pre>void(*void USBD_CORE_API::StatusOutStage)(USBD_HANDLE_T hUsb)</pre>
	Function to set EP0 state machine in status_out state.
	This function is called by USB stack and the application layer to set the EP0 state machine in status_out state. This function will read the zero length OUT packet received from USB host on EP0.
	<b>Remark:</b> This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.  Parameters:
	hUsb = Handle to the USB device stack.
	Returns:
	Nothing.

Table 194. USBD\_CORE\_API class structure

Member	Description
StallEp0	<pre>void(*void USBD_CORE_API::StallEp0)(USBD_HANDLE_T hUsb)</pre>
	Function to set EP0 state machine in stall state.
	This function is called by USB stack and the application layer to generate STALL signalling on EP0 endpoint. This function will also reset the EP0Data buffer.
	<b>Remark:</b> This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	Returns:
	Nothing.

### 11.5.30 USBD\_DFU\_API

DFU class API functions structure. This module exposes functions which interact directly with USB device controller hardware.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 195. USBD\_DFU\_API class structure

Member	Description
GetMemSize	uint32_t(*uint32_t USBD_DFU_API::GetMemSize)(USBD_DFU_INIT_PARAM_T *param)
	Function to determine the memory required by the DFU function driver module.
	This function is called by application layer before calling pUsbApi->dfu->Init(), to allocate memory used by DFU function driver module. The application should allocate the memory which is accessible by USB controller/DMA controller.
	Remark: Some memory areas are not accessible by all bus masters.
	Parameters:
	<ol> <li>param = Structure containing DFU function driver module initialization parameters.</li> </ol>
	Returns:
	Returns the required memory size in bytes.
init	<pre>ErrorCode_t(*ErrorCode_t USBD_DFU_API::init)(USBD_HANDLE_T hUsb, USBD_DFU_INIT_PARAM_T     *param, uint32_t init_state)</pre>
	Function to initialize DFU function driver module.
	This function is called by application layer to initialize DFU function driver module.
	hUsbHandle to the USB device stack. paramStructure containing DFU function driver module initialization parameters.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. param = Structure containing DFU function driver module initialization parameters.
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success
	<ol><li>ERR_USBD_BAD_MEM_BUF = Memory buffer passed is not 4-byte aligned or smaller than required.</li></ol>
	<ol><li>ERR_API_INVALID_PARAM2 = Either DFU_Write() or DFU_Done() or DFU_Read() callbacks are not defined.</li></ol>
	4. ERR_USBD_BAD_DESC = USB_DFU_DESCRIPTOR_TYPE is not defined immediately after interface descriptor.wTransferSize in descriptor doesn't match the value passed in param->wTransferSize.DFU_Detach() is not defined while USB_DFU_WILL_DETACH is set in DFU descriptor.
	5. ERR_USBD_BAD_INTF_DESC = Wrong interface descriptor is passed.

## 11.5.31 USBD\_DFU\_INIT\_PARAM

USB descriptors data structure.

UM10524 **NXP Semiconductors** 

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 196, USBD\_DFU\_INIT\_PARAM class structure

Table 196. USBL	D_DFU_INIT_PARAM class structure
Member	Description
mem_base	uint32_tuint32_t USBD_DFU_INIT_PARAM::mem_base
	Base memory location from where the stack can allocate data and buffers.
	<b>Remark:</b> The memory address set in this field should be accessible by USB DMA controller. Also this value should be aligned on 4 byte boundary.
mem_size	uint32_tuint32_t USBD_DFU_INIT_PARAM::mem_size
	The size of memory buffer which stack can use.
	<b>Remark:</b> The mem_size should be greater than the size returned by USBD_DFU_API::GetMemSize() routine.
wTransferSize	uint16_tuint16_t USBD_DFU_INIT_PARAM::wTransferSize
	DFU transfer block size in number of bytes. This value should match the value set in DFU descriptor provided as part of the descriptor array (
pad	uint16_tuint16_t USBD_DFU_INIT_PARAM::pad
intf_desc	uint8_t *uint8_t* USBD_DFU_INIT_PARAM::intf_desc
	Pointer to the DFU interface descriptor within the descriptor array (
DFU_Write	<pre>uint8_t(*uint8_t(* USBD_DFU_INIT_PARAM::DFU_Write)(uint32_t block_num, uint8_t **src, uint32_t length, uint8_t *bwPollTimeout))(uint32_t block_num, uint8_t **src, uint32_t length, uint8_t *bwPollTimeout)</pre>
	DFU Write callback function.
	This function is provided by the application software. This function gets called when host sends a write command. For application using zero-copy buffer scheme this function is called for the first time with
	block_numDestination start address. srcPointer to a pointer to the source of data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept. bwPollTimeoutPointer to a 3 byte buffer which the callback implementer should fill with the amount of minimum time, in milliseconds, that the host should wait before sending a subsequent DFU_GETSTATUS request. lengthNumber of bytes to be written.
	Parameters:
	<ol> <li>block_num = Destination start address.</li> </ol>
	<ol><li>src = Pointer to a pointer to the source of data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept.</li></ol>
	<ol><li>bwPollTimeout = Pointer to a 3 byte buffer which the callback implementer should fill with the amount of minimum time, in milliseconds, that the host should wait before sending a subsequent</li></ol>

- DFU\_GETSTATUS request.
- 4. length = Number of bytes to be written.

Returns DFU\_STATUS\_ values defined in mw\_usbd\_dfu.h.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

### Table 196. USBD\_DFU\_INIT\_PARAM class structure

Description
<pre>uint32_t(*uint32_t(* USBD_DFU_INIT_PARAM::DFU_Read)(uint32_t block_num, uint8_t **dst,</pre>
DFU Read callback function.
This function is provided by the application software. This function gets called when host sends a read command.
block_numDestination start address. dstPointer to a pointer to the source of data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept. lengthAmount of data copied to destination buffer.
Parameters:
<ol> <li>block_num = Destination start address.</li> </ol>
<ol> <li>dst = Pointer to a pointer to the source of data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept.</li> </ol>
3. length = Amount of data copied to destination buffer.
Returns:
Returns DFU_STATUS_ values defined in mw_usbd_dfu.h.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 196. USBD\_DFU\_INIT\_PARAM class structure

Member	Description
DFU_Done	<pre>void(*void(* USBD_DFU_INIT_PARAM::DFU_Done)(void))(void)</pre>
	DFU done callback function.
	This function is provided by the application software. This function gets called after download is finished.
	Nothing.
	Returns:
	Nothing.
DFU_Detach	<pre>void(*void(* USBD_DFU_INIT_PARAM::DFU_Detach)(USBD_HANDLE_T hUsb))(USBD_HANDLE_T hUsb)</pre>
	DFU detach callback function.
	This function is provided by the application software. This function gets called after USB_REQ_DFU_DETACH is received. Applications which set USB_DFU_WILL_DETACH bit in DFU descriptor should define this function. As part of this function application can call Connect() routine to disconnect and then connect back with host. For application which rely on WinUSB based host application should use this feature since USB reset can be invoked only by kernel drivers on Windows host. By implementing this feature host doesn't have to issue reset instead the device has to do it automatically by disconnect and connect procedure.
	hUsbHandle DFU control structure.
	Parameters:
	hUsb = Handle DFU control structure.
	Returns:
	Nothing.
DFU_Ep0_Hdlr	<pre>ErrorCode_t(*ErrorCode_t(* USBD_DFU_INIT_PARAM::DFU_Ep0_Hdlr)(USBD_HANDLE_T hUsb, void</pre>
	Optional user overridable function to replace the default DFU class handler.
	The application software could override the default EP0 class handler with their own by providing the handler function address as this data member of the parameter structure. Application which like the default handler should set this data member to zero before calling the USBD_DFU_API::Init().
	Remark:
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. data = Pointer to the data which will be passed when callback function is called by the stack.
	<ol><li>event = Type of endpoint event. See USBD_EVENT_T for more details.</li></ol>
	Returns:
	The call back should returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success.
	2. ERR_USBD_UNHANDLED = Event is not handled hence pass the event to next in line.
	<ol><li>ERR_USBD_xxx = For other error conditions.</li></ol>

### 11.5.32 USBD\_HID\_API

HID class API functions structure. This structure contains pointers to all the function exposed by HID function driver module.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

### Table 197. USBD\_HID\_API class structure

Member	Description
GetMemSize	uint32_t(*uint32_t USBD_HID_API::GetMemSize)(USBD_HID_INIT_PARAM_T *param)
	Function to determine the memory required by the HID function driver module.
	This function is called by application layer before calling pUsbApi->hid->Init(), to allocate memory used by HID function driver module. The application should allocate the memory which is accessible by USB controller/DMA controller.
	Remark: Some memory areas are not accessible by all bus masters.
	Parameters:
	<ol> <li>param = Structure containing HID function driver module initialization parameters.</li> </ol>
	Returns:
	Returns the required memory size in bytes.
init	<pre>ErrorCode_t(*ErrorCode_t USBD_HID_API::init)(USBD_HANDLE_T hUsb, USBD_HID_INIT_PARAM_T     *param)</pre>
	Function to initialize HID function driver module.
	This function is called by application layer to initialize HID function driver module. On successful initialization the function returns a handle to HID function driver module in passed param structure.
	hUsbHandle to the USB device stack. paramStructure containing HID function driver module initialization parameters.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. param = Structure containing HID function driver module initialization parameters.
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success
	<ol><li>ERR_USBD_BAD_MEM_BUF = Memory buffer passed is not 4-byte aligned or smaller than required.</li></ol>
	<ol><li>ERR_API_INVALID_PARAM2 = Either HID_GetReport() or HID_SetReport() callback are not defined.</li></ol>
	<ol> <li>ERR_USBD_BAD_DESC = HID_HID_DESCRIPTOR_TYPE is not defined immediately after interface descriptor.</li> </ol>
	<ol><li>ERR_USBD_BAD_INTF_DESC = Wrong interface descriptor is passed.</li></ol>
	<ol><li>ERR_USBD_BAD_EP_DESC = Wrong endpoint descriptor is passed.</li></ol>

## 11.5.33 USBD\_HID\_INIT\_PARAM

USB descriptors data structure.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 198. USBD\_HID\_INIT\_PARAM class structure

Member	Description
mem_base	uint32_tuint32_t USBD_HID_INIT_PARAM::mem_base
	Base memory location from where the stack can allocate data and buffers.
	<b>Remark:</b> The memory address set in this field should be accessible by USB DMA controller. Also this value should be aligned on 4 byte boundary.
mem_size	uint32_tuint32_t USBD_HID_INIT_PARAM::mem_size
	The size of memory buffer which stack can use.
	<b>Remark:</b> The mem_size should be greater than the size returned by USBD_HID_API::GetMemSize() routine.
max_reports	uint8_tuint8_t USBD_HID_INIT_PARAM::max_reports
	Number of HID reports supported by this instance of HID class driver.
pad	uint8_tuint8_t USBD_HID_INIT_PARAM::pad[3][3]
intf_desc	uint8_t *uint8_t* USBD_HID_INIT_PARAM::intf_desc
	Pointer to the HID interface descriptor within the descriptor array (
report_data	USB_HID_REPORT_T *USB_HID_REPORT_T* USBD_HID_INIT_PARAM::report_data
	Pointer to an array of HID report descriptor data structure (
	Remark: This array should be of global scope.
HID_GetReport	<pre>ErrorCode_t(*ErrorCode_t(* USBD_HID_INIT_PARAM::HID_GetReport)(USBD_HANDLE_T hHid,</pre>
	HID get report callback function.
	This function is provided by the application software. This function gets called when host sends a HID_REQUEST_GET_REPORT request. The setup packet data (
	<b>Remark:</b> HID reports are sent via interrupt IN endpoint also. This function is called only when report request is received on control endpoint. Application should implement HID_EpIn_Hdlr to send reports to host via interrupt IN endpoint.
	Parameters:
	hHid = Handle to HID function driver.
	<ol><li>pSetup = Pointer to setup packet received from host.</li></ol>
	<ol> <li>pBuffer = Pointer to a pointer of data buffer containing report data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept.</li> </ol>
	4. length = Amount of data copied to destination buffer.
	Returns:
	The call back should returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success.
	2. ERR_USBD_UNHANDLED = Event is not handled hence pass the event to next in line.
	3. ERR_USBD_xxx = For other error conditions.

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 198. USBD\_HID\_INIT\_PARAM class structure

#### Member

#### Description

HID\_SetReport

HID set report callback function.

This function is provided by the application software. This function gets called when host sends a HID\_REQUEST\_SET\_REPORT request. The setup packet data (

hHidHandle to HID function driver. pSetupPointer to setup packet received from host. pBufferPointer to a pointer of data buffer containing report data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept. lengthAmount of data copied to destination buffer.

#### Parameters:

- 1. hHid = Handle to HID function driver.
- 2. pSetup = Pointer to setup packet received from host.
- pBuffer = Pointer to a pointer of data buffer containing report data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept.
- 4. length = Amount of data copied to destination buffer.

#### Returns:

The call back should returns ErrorCode\_t type to indicate success or error condition.

#### Return values:

- 1. LPC\_OK = On success.
- 2. ERR\_USBD\_UNHANDLED = Event is not handled hence pass the event to next in line.
- 3. ERR\_USBD\_xxx = For other error conditions.

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 198. USBD\_HID\_INIT\_PARAM class structure

#### Member

#### Description

#### HID\_GetPhysDesc

Optional callback function to handle HID\_GetPhysDesc request.

The application software could provide this callback HID\_GetPhysDesc handler to handle get physical descriptor requests sent by the host. When host requests Physical Descriptor set 0, application should return a special descriptor identifying the number of descriptor sets and their sizes. A Get\_Descriptor request with the Physical Index equal to 1 should return the first Physical Descriptor set. A device could possibly have alternate uses for its items. These can be enumerated by issuing subsequent Get\_Descriptor requests while incrementing the Descriptor Index. A device should return the last descriptor set to requests with an index greater than the last number defined in the HID descriptor.

**Remark:** Applications which don't have physical descriptor should set this data member to zero before calling the USBD\_HID\_API::Init().

#### Parameters:

- 1. hHid = Handle to HID function driver.
- 2. pSetup = Pointer to setup packet received from host.
- 3. pBuf = Pointer to a pointer of data buffer containing physical descriptor data. If the physical descriptor is in USB accessible memory area application could just update the pointer or else it should copy the descriptor to the address pointed by this pointer.
- 4. length = Amount of data copied to destination buffer or descriptor length.

#### Returns:

The call back should returns ErrorCode\_t type to indicate success or error condition.

#### Return values:

- 1. LPC\_OK = On success.
- 2. ERR\_USBD\_UNHANDLED = Event is not handled hence pass the event to next in line.
- 3. ERR USBD xxx = For other error conditions.

#### HID\_SetIdle

Optional callback function to handle HID\_REQUEST\_SET\_IDLE request.

The application software could provide this callback to handle HID\_REQUEST\_SET\_IDLE requests sent by the host. This callback is provided to applications to adjust timers associated with various reports, which are sent to host over interrupt endpoint. The setup packet data (

**Remark:** Applications which don't send reports on Interrupt endpoint or don't have idle time between reports should set this data member to zero before calling the USBD\_HID\_API::Init().

#### Parameters:

- 1. hHid = Handle to HID function driver.
- 2. pSetup = Pointer to setup packet recived from host.
- 3. idleTime = Idle time to be set for the specified report.

#### Returns:

The call back should returns ErrorCode t type to indicate success or error condition.

#### Return values:

- 1. LPC\_OK = On success.
- 2. ERR\_USBD\_UNHANDLED = Event is not handled hence pass the event to next in line.
- 3. ERR\_USBD\_xxx = For other error conditions.

	<ol><li>ERR_USBD_xxx = For other error conditions.</li></ol>

## 11.5.34 USBD\_HW\_API

Hardware API functions structure. This module exposes functions which interact directly with USB device controller hardware.

## Chapter 11: LPC1345/46/47 USB on-chip drivers

### Table 199. USBD\_HW\_API class structure

Member	Description
GetMemSize	uint32_t(*uint32_t USBD_HW_API::GetMemSize)(USBD_API_INIT_PARAM_T *param)
	Function to determine the memory required by the USB device stack's DCD and core layers.
	This function is called by application layer before calling pUsbApi->hw->
	Remark: Some memory areas are not accessible by all bus masters.
	Parameters:
	<ol> <li>param = Structure containing USB device stack initialization parameters.</li> </ol>
	Returns:
	Returns the required memory size in bytes.
Init	<pre>ErrorCode_t(*ErrorCode_t USBD_HW_API::Init)(USBD_HANDLE_T *phUsb, USB_CORE_DESCS_T     *pDesc, USBD_API_INIT_PARAM_T *param)</pre>
	Function to initialize USB device stack's DCD and core layers.
	This function is called by application layer to initialize USB hardware and core layers. On successful initialization the function returns a handle to USB device stack which should be passed to the rest of the functions.
	phUsbPointer to the USB device stack handle of type USBD_HANDLE_T. paramStructure containing USB device stack initialization parameters.
	Parameters:
	<ol> <li>phUsb = Pointer to the USB device stack handle of type USBD_HANDLE_T.</li> </ol>
	<ol><li>param = Structure containing USB device stack initialization parameters.</li></ol>
	Returns:
	Returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK(0) = On success
	<ol><li>ERR_USBD_BAD_MEM_BUF(0x0004000b) = When insufficient memory buffer is passed or memory is not aligned on 2048 boundary.</li></ol>
Connect	<pre>void(*void USBD_HW_API::Connect)(USBD_HANDLE_T hUsb, uint32_t con)</pre>
	Function to make USB device visible/invisible on the USB bus.
	This function is called after the USB initialization. This function uses the soft connect feature to make the device visible on the USB bus. This function is called only after the application is ready to handle the USB data. The enumeration process is started by the host after the device detection. The driver handles the enumeration process according to the USB descriptors passed in the USB initialization function.
	hUsbHandle to the USB device stack. conStates whether to connect (1) or to disconnect (0). Parameters:
	1. hUsb = Handle to the USB device stack.
	2. con = States whether to connect (1) or to disconnect (0).
	Returns:
	Nothing.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 199. USBD\_HW\_API class structure

Member	Description
ISR	<pre>void(*void USBD_HW_API::ISR)(USBD_HANDLE_T hUsb)</pre>
	Function to USB device controller interrupt events.
	When the user application is active the interrupt handlers are mapped in the user flash space. The user application must provide an interrupt handler for the USB interrupt and call this function in the interrupt handler routine. The driver interrupt handler takes appropriate action according to the data received on the USB bus.
	hUsbHandle to the USB device stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	Returns:
	Nothing.
Reset	void(*void USBD_HW_API::Reset)(USBD_HANDLE_T hUsb)
	Function to Reset USB device stack and hardware controller.
	Reset USB device stack and hardware controller. Disables all endpoints except EP0. Clears all pending interrupts and resets endpoint transfer queues. This function is called internally by pUsbApi->hw->init() and from reset event.
	hUsbHandle to the USB device stack.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	Returns:
	Nothing.
ForceFullSpeed	<pre>void(*void USBD_HW_API::ForceFullSpeed)(USBD_HANDLE_T hUsb, uint32_t cfg)</pre>
	Function to force high speed USB device to operate in full speed mode.
	This function is useful for testing the behavior of current device when connected to a full speed only hosts.
	hUsbHandle to the USB device stack. cfgWhen 1 - set force full-speed or 0 - clear force full-speed.
	Parameters:
	1. hUsb = Handle to the USB device stack.
	2. cfg = When 1 - set force full-speed or 0 - clear force full-speed.
	Returns:
	Nothing.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 199. USBD\_HW\_API class structure

Table 199. USBD_HW_API class structure		
Member	Description	
WakeUpCfg	<pre>void(*void USBD_HW_API::WakeUpCfg)(USBD_HANDLE_T hUsb, uint32_t cfg)</pre>	
	Function to configure USB device controller to walk-up host on remote events.	
	This function is called by application layer to configure the USB device controller to wake up on remote events. It is recommended to call this function from users's USB_WakeUpCfg() callback routine registered with stack.	
	<b>Remark:</b> User's USB_WakeUpCfg() is registered with stack by setting the USB_WakeUpCfg member of USBD_API_INIT_PARAM_T structure before calling pUsbApi->hw->Init() routine. Certain USB device controllers needed to keep some clocks always on to generate resume signaling through pUsbApi->hw->WakeUp(). This hook is provided to support such controllers. In most controllers cases this is an empty routine.	
	Parameters:	
	1. hUsb = Handle to the USB device stack.	
	<ol><li>cfg = When 1 - Configure controller to wake on remote events or 0 - Configure controller not to wake on remote events.</li></ol>	
	Returns:	
	Nothing.	
SetAddress	<pre>void(*void USBD_HW_API::SetAddress)(USBD_HANDLE_T hUsb, uint32_t adr)</pre>	
	Function to set USB address assigned by host in device controller hardware.	
	This function is called automatically when USB_REQUEST_SET_ADDRESS request is received by the stack from USB host. This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.	
	hUsbHandle to the USB device stack. adrUSB bus Address to which the device controller should respond. Usually assigned by the USB host.	
	Parameters:	
	1. hUsb = Handle to the USB device stack.	
	<ol><li>adr = USB bus Address to which the device controller should respond. Usually assigned by the USB host.</li></ol>	
	Returns:	
	Nothing.	
Configure	void(*void USBD_HW_API::Configure)(USBD_HANDLE_T hUsb, uint32_t cfg)	
	Function to configure device controller hardware with selected configuration.	
	This function is called automatically when USB_REQUEST_SET_CONFIGURATION request is received by the stack from USB host. This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.	
	hUsbHandle to the USB device stack. cfgConfiguration index.	
	Parameters:	
	1. hUsb = Handle to the USB device stack.	
	2. cfg = Configuration index.	
	Returns:	
	Nothing.	

**UM10524 NXP Semiconductors** 

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Member	Description				
ConfigEP	void(*void USBD_HW_API::ConfigEP)(USBD_HANDLE_T hUsb, USB_ENDPOINT_DESCRIPTOR *pEPD)				
	Function to configure USB Endpoint according to descriptor.				
	This function is called automatically when USB_REQUEST_SET_CONFIGURATION request is received by the stack from USB host. All the endpoints associated with the selected configuration are configured. This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.				
	hUsbHandle to the USB device stack. pEPDEndpoint descriptor structure defined in USB 2.0 specification.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	<ol><li>pEPD = Endpoint descriptor structure defined in USB 2.0 specification.</li></ol>				
	Returns:				
	Nothing.				
DirCtrlEP	<pre>void(*void USBD_HW_API::DirCtrlEP)(USBD_HANDLE_T hUsb, uint32_t dir)</pre>				
	Function to set direction for USB control endpoint EP0.				
	This function is called automatically by the stack on need basis. This interface is provided to users to invoke this function in other scenarios which are not handle by current stack. In most user applications this function is not called directly. Also this function can be used by users who are selectively modifying the USB device stack's standard handlers through callback interface exposed by the stack.				
	hUsbHandle to the USB device stack. cfgWhen 1 - Set EP0 in IN transfer mode 0 - Set EP0 in OUT transfer mode				
	Parameters:				
	hUsb = Handle to the USB device stack.				
	2. cfg = When 1 - Set EP0 in IN transfer mode 0 - Set EP0 in OUT transfer mode				
	Returns:				
	Nothing.				

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Member	Description				
EnableEP	void(*void USBD_HW_API::EnableEP)(USBD_HANDLE_T hUsb, uint32_t EPNum)				
	Function to enable selected USB endpoint.				
	This function enables interrupts on selected endpoint.				
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>				
	Returns:				
	Nothing.				
	This function enables interrupts on selected endpoint.				
	hUsbHandle to the USB device stack. EPNumEndpoint number corresponding to the event as per USB specification. ie. An EP1_IN is represented by 0x81 number. For device events set this param to 0x0. eventType of endpoint event. See USBD_EVENT_T for more details. enable1 - enable event, 0 - disable event.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	<ol><li>EPNum = Endpoint number corresponding to the event as per USB specification. ie. An EP1_IN is represented by 0x81 number. For device events set this param to 0x0.</li></ol>				
	<ol><li>event = Type of endpoint event. See USBD_EVENT_T for more details.</li></ol>				
	4. enable = 1 - enable event, 0 - disable event.				
	Returns:				
	Returns ErrorCode_t type to indicate success or error condition.				
	Return values:				
	1. LPC_OK(0) = - On success				
	2. ERR_USBD_INVALID_REQ(0x00040001) = - Invalid event type.				
DisableEP	void(*void USBD_HW_API::DisableEP)(USBD_HANDLE_T hUsb, uint32_t EPNum)				
	Function to disable selected USB endpoint.				
	This function disables interrupts on selected endpoint.				
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>				
	Returns:				
	Nothing.				

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Member	Description			
ResetEP	<pre>void(*void USBD_HW_API::ResetEP)(USBD_HANDLE_T hUsb, uint32_t EPNum)</pre>			
	Function to reset selected USB endpoint.			
	This function flushes the endpoint buffers and resets data toggle logic.			
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.			
	Parameters:			
	<ol> <li>hUsb = Handle to the USB device stack.</li> </ol>			
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>			
	Returns:			
	Nothing.			
SetStallEP	void(*void USBD_HW_API::SetStallEP)(USBD_HANDLE_T hUsb, uint32_t EPNum)			
	Function to STALL selected USB endpoint.			
	Generates STALL signalling for requested endpoint.			
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.			
	Parameters:			
	1. hUsb = Handle to the USB device stack.			
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>			
	Returns:			
	Nothing.			
CIrStallEP	void(*void USBD_HW_API::ClrStallEP)(USBD_HANDLE_T hUsb, uint32_t EPNum)			
	Function to clear STALL state for the requested endpoint.			
	This function clears STALL state for the requested endpoint.			
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.			
	Parameters:			
	1. hUsb = Handle to the USB device stack.			
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>			
	Returns:			
	Nothing.

#### Table 199. USBD HW API class structure

Table 199. USBD_HW_API class structure					
Member	Description				
SetTestMode	<pre>ErrorCode_t(*ErrorCode_t USBD_HW_API::SetTestMode)(USBD_HANDLE_T hUsb, uint8_t mode)</pre>				
	Function to set high speed USB device controller in requested test mode.				
	USB-IF requires the high speed device to be put in various test modes for electrical testing. This USB device stack calls this function whenever it receives USB_REQUEST_CLEAR_FEATURE request for USB_FEATURE_TEST_MODE. Users can put the device in test mode by directly calling this function. Returns ERR_USBD_INVALID_REQ when device controller is full-speed only.				
	hUsbHandle to the USB device stack. modeTest mode defined in USB 2.0 electrical testing specification.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	2. mode = Test mode defined in USB 2.0 electrical testing specification.				
	Returns:				
	Returns ErrorCode_t type to indicate success or error condition.				
	Return values:				
	1. LPC_OK(0) = - On success				
	<ol> <li>ERR_USBD_INVALID_REQ(0x00040001) = - Invalid test mode or Device controller is full-speed only.</li> </ol>				
ReadEP	<pre>uint32_t(*uint32_t USBD_HW_API::ReadEP)(USBD_HANDLE_T hUsb, uint32_t EPNum, uint8_t     *pData)</pre>				
	Function to read data received on the requested endpoint.				
	This function is called by USB stack and the application layer to read the data received on the requested endpoint.				
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number. pDataPointer to the data buffer where data is to be copied.				
	Parameters:				
	hUsb = Handle to the USB device stack.				
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>				
	<ol><li>pData = Pointer to the data buffer where data is to be copied.</li></ol>				
	Returns:				
	Returns the number of bytes copied to the buffer.				

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Description					
uint32_t(*uint32_t USBD_HW_API::ReadReqEP)(USBD_HANDLE_T hUsb, uint32_t EPNum, uint8_t *pData, uint32_t len)					
Function to queue read request on the specified endpoint.					
This function is called by USB stack and the application layer to queue a read request on the specified endpoint.					
hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number. pDataPointer to the data buffer where data is to be copied. This buffer address should be accessible by USB DMA master. lenLength of the buffer passed.					
Parameters:					
1. hUsb = Handle to the USB device stack.					
<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>					
<ol><li>pData = Pointer to the data buffer where data is to be copied. This buffer address should be accessible by USB DMA master.</li></ol>					
4. len = Length of the buffer passed.					
Returns:					
Returns the length of the requested buffer.					
<pre>uint32_t(*uint32_t USBD_HW_API::ReadSetupPkt)(USBD_HANDLE_T hUsb, uint32_t EPNum,</pre>					
Function to read setup packet data received on the requested endpoint.					
This function is called by USB stack and the application layer to read setup packet data received on the requested endpoint.					
hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP0_IN is represented by 0x80 number. pDataPointer to the data buffer where data is to be copied.					
Parameters:					
1. hUsb = Handle to the USB device stack.					
<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP0_IN is represented by 0x80 number.</li></ol>					
3. pData = Pointer to the data buffer where data is to be copied.					
Returns:					
Returns the number of bytes copied to the buffer.					

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Member	Description				
WriteEP	uint32_t(*uint32_t USBD_HW_API::WriteEP)(USBD_HANDLE_T hUsb, uint32_t EPNum, uint8_t *pData, uint32_t cnt)				
	Function to write data to be sent on the requested endpoint.				
	This function is called by USB stack and the application layer to send data on the requested endpoint.				
	hUsbHandle to the USB device stack. EPNumEndpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number. pDataPointer to the data buffer from where data is to be copied. cntNumber of bytes to write.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	<ol><li>EPNum = Endpoint number as per USB specification. ie. An EP1_IN is represented by 0x81 number.</li></ol>				
	3. pData = Pointer to the data buffer from where data is to be copied.				
	4. cnt = Number of bytes to write.				
	Returns:				
	Returns the number of bytes written.				
WakeUp	<pre>void(*void USBD_HW_API::WakeUp)(USBD_HANDLE_T hUsb)</pre>				
	Function to generate resume signaling on bus for remote host wake-up.				
	This function is called by application layer to remotely wake up host controller when system is in suspend state. Application should indicate this remote wake up capability by setting USB_CONFIG_REMOTE_WAKEUP in bmAttributes of Configuration Descriptor. Also this routine will generate resume signalling only if host enables USB_FEATURE_REMOTE_WAKEUP by sending SET_FEATURE request before suspending the bus.				
	hUsbHandle to the USB device stack.				
	Parameters:				
	1. hUsb = Handle to the USB device stack.				
	Returns:				
	Nothing.				
EnableEvent	<pre>ErrorCode_t(*ErrorCode_t(* USBD_HW_API::EnableEvent)(USBD_HANDLE_T hUsb, uint32_t EPNum,</pre>				

## 11.5.35 USBD\_MSC\_API

MSC class API functions structure. This module exposes functions which interact directly with USB device controller hardware.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 200. USBD\_MSC\_API class structure

Member	Description				
GetMemSize	uint32_t(*uint32_t USBD_MSC_API::GetMemSize)(USBD_MSC_INIT_PARAM_T *param)				
	Function to determine the memory required by the MSC function driver module.				
	This function is called by application layer before calling pUsbApi->msc->Init(), to allocate memory used by MSC function driver module. The application should allocate the memory which is accessible by USB controller/DMA controller.				
	Remark: Some memory areas are not accessible by all bus masters.				
	Parameters:				
	1. param = Structure containing MSC function driver module initialization parameters.				
	Returns:				
	Returns the required memory size in bytes.				
init	<pre>ErrorCode_t(*ErrorCode_t USBD_MSC_API::init)(USBD_HANDLE_T hUsb,</pre>				
	Function to initialize MSC function driver module.				
	This function is called by application layer to initialize MSC function driver module.				
	hUsbHandle to the USB device stack. paramStructure containing MSC function driver module initialization parameters.				
	Parameters:				
	<ol> <li>hUsb = Handle to the USB device stack.</li> </ol>				
	<ol> <li>param = Structure containing MSC function driver module initialization parameters.</li> <li>Returns:</li> </ol>				
	Returns ErrorCode_t type to indicate success or error condition.				
	Return values:				
	1. LPC OK = On success				
	<ol> <li>ERR_USBD_BAD_MEM_BUF = Memory buffer passed is not 4-byte aligned or smaller than required.</li> </ol>				
	<ol> <li>ERR_API_INVALID_PARAM2 = Either MSC_Write() or MSC_Read() or MSC_Verify() callbacks are not defined.</li> </ol>				
	4. ERR_USBD_BAD_INTF_DESC = Wrong interface descriptor is passed.				
	5. ERR_USBD_BAD_EP_DESC = Wrong endpoint descriptor is passed.				

### 11.5.36 USBD\_MSC\_INIT\_PARAM

Mass Storage class function driver initialization parameter data structure.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

Table 201. USBD\_MSC\_INIT\_PARAM class structure

Member	Description				
mem_base	uint32_tuint32_t USBD_MSC_INIT_PARAM::mem_base				
	Base memory location from where the stack can allocate data and buffers.				
	<b>Remark:</b> The memory address set in this field should be accessible by USB DMA controller. Also this value should be aligned on 4 byte boundary.				
mem_size	uint32_tuint32_t USBD_MSC_INIT_PARAM::mem_size				
	The size of memory buffer which stack can use.				
	<b>Remark:</b> The mem_size should be greater than the size returned by USBD_MSC_API::GetMemSize() routine.				
InquiryStr	uint8_t *uint8_t* USBD_MSC_INIT_PARAM::InquiryStr				
	Pointer to the 28 character string. This string is sent in response to the SCSI Inquiry command.				
	Remark: The data pointed by the pointer should be of global scope.				
BlockCount	uint32_tuint32_t USBD_MSC_INIT_PARAM::BlockCount				
	Number of blocks present in the mass storage device				
BlockSize	uint32_tuint32_t USBD_MSC_INIT_PARAM::BlockSize				
	Block size in number of bytes				
MemorySize	uint32_tuint32_t USBD_MSC_INIT_PARAM::MemorySize				
	Memory size in number of bytes				
intf_desc	uint8_t *uint8_t* USBD_MSC_INIT_PARAM::intf_desc				
	Pointer to the interface descriptor within the descriptor array (				
MSC_Write	<pre>void(*void(* USBD_MSC_INIT_PARAM::MSC_Write)(uint32_t offset, uint8_t **src, uint32_t length))(uint32_t offset, uint8_t **src, uint32_t length)</pre>				
	MSC Write callback function.				
	This function is provided by the application software. This function gets called when host sends a write command.				
	offsetDestination start address. srcPointer to a pointer to the source of data.  Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept. lengthNumber of bytes to be written.				
	Parameters:				
	offset = Destination start address.				
	<ol> <li>src = Pointer to a pointer to the source of data. Pointer-to-pointer is used to implement zero-copy buffers. See Zero-Copy Data Transfer model for more details on zero-copy concept.</li> </ol>				
	3. length = Number of bytes to be written.				
	Returns:				
	Returns.				

#### Chapter 11: LPC1345/46/47 USB on-chip drivers

#### Table 201. USBD\_MSC\_INIT\_PARAM class structure

#### Member

#### Description

MSC\_Read

MSC Read callback function.

This function is provided by the application software. This function gets called when host sends a read command.

offsetSource start address. dstPointer to a pointer to the source of data. The MSC function drivers implemented in stack are written with zero-copy model. Meaning the stack doesn't make an extra copy of buffer before writing/reading data from USB hardware FIFO. Hence the parameter is pointer to a pointer containing address buffer (uint8\_t\*\* dst). So that the user application can update the buffer pointer instead of copying data to address pointed by the parameter. /note The updated buffer address should be accessible by USB DMA master. If user doesn't want to use zero-copy model, then the user should copy data to the address pointed by the passed buffer pointer parameter and shouldn't change the address value. See Zero-Copy Data Transfer model for more details on zero-copy concept. lengthNumber of bytes to be read.

#### Parameters:

- 1. offset = Source start address.
- 2. dst = Pointer to a pointer to the source of data. The MSC function drivers implemented in stack are written with zero-copy model. Meaning the stack doesn't make an extra copy of buffer before writing/reading data from USB hardware FIFO. Hence the parameter is pointer to a pointer containing address buffer (uint8\_t\*\* dst). So that the user application can update the buffer pointer instead of copying data to address pointed by the parameter. /note The updated buffer address should be access able by USB DMA master. If user doesn't want to use zero-copy model, then the user should copy data to the address pointed by the passed buffer pointer parameter and shouldn't change the address value. See Zero-Copy Data Transfer model for more details on zero-copy concept.
- 3. length = Number of bytes to be read.

Returns:

Nothing.

### Chapter 11: LPC1345/46/47 USB on-chip drivers

## Table 201. USBD\_MSC\_INIT\_PARAM class structure

Member	Description				
MSC_Verify	<pre>ErrorCode_t(*ErrorCode_t(* USBD_MSC_INIT_PARAM::MSC_Verify)(uint32_t offset, uint8_t buf[], uint32_t length))(uint32_t offset, uint8_t buf[], uint32_t length)</pre>				
	MSC Verify callback function.				
	This function is provided by the application software. This function gets called when host sends a verify command. The callback function should compare the buffer with the destination memory at the requested offset and				
	offsetDestination start address. bufBuffer containing the data sent by the host. lengthNumber of bytes to verify.				
	Parameters:				
	offset = Destination start address.				
	2. buf = Buffer containing the data sent by the host.				
	<ol><li>length = Number of bytes to verify.</li></ol>				
	Returns:				
	Returns ErrorCode_t type to indicate success or error condition.				
	Return values:				
	<ol> <li>LPC_OK = If data in the buffer matches the data at destination</li> </ol>				
	2. ERR_FAILED = At least one byte is different.				
MSC_GetWriteBuf	<pre>void(*void(* USBD_MSC_INIT_PARAM::MSC_GetWriteBuf)(uint32_t offset, uint8_t</pre>				
	Optional callback function to optimize MSC_Write buffer transfer.				
	This function is provided by the application software. This function gets called when host sends SCSI_WRITE10/SCSI_WRITE12 command. The callback function should update the				
	offsetDestination start address. bufBuffer containing the data sent by the host. lengthNumber of bytes to write.				
	Parameters:				
	offset = Destination start address.				
	2. buf = Buffer containing the data sent by the host.				
	3. length = Number of bytes to write.				
	Returns:				
	Nothing.				

### Chapter 11: LPC1345/46/47 USB on-chip drivers

### Table 201. USBD\_MSC\_INIT\_PARAM class structure

Member	Description
MSC_Ep0_Hdlr	<pre>ErrorCode_t(*ErrorCode_t(* USBD_MSC_INIT_PARAM::MSC_Ep0_Hdlr)(USBD_HANDLE_T     hUsb, void *data, uint32_t event))(USBD_HANDLE_T hUsb, void *data, uint32_t     event)</pre>
	Optional user overridable function to replace the default MSC class handler.
	The application software could override the default EP0 class handler with their own by providing the handler function address as this data member of the parameter structure. Application which like the default handler should set this data member to zero before calling the USBD_MSC_API::Init().
	Remark:
	Parameters:
	1. hUsb = Handle to the USB device stack.
	<ol><li>data = Pointer to the data which will be passed when callback function is called by the stack.</li></ol>
	<ol><li>event = Type of endpoint event. See USBD_EVENT_T for more details.</li></ol>
	Returns:
	The call back should returns ErrorCode_t type to indicate success or error condition.
	Return values:
	1. LPC_OK = On success.
	<ol> <li>ERR_USBD_UNHANDLED = Event is not handled hence pass the event to next in line.</li> <li>ERR_USBD_xxx = For other error conditions.</li> </ol>

# UM10524

## Chapter 12: LPC1315/16/17/45/46/47 USART

Rev. 4 — 12 March 2013

**User manual** 

## 12.1 How to read this chapter

The USART controller is available on all LPC1315/16/17/45/46/47 parts.

## 12.2 Basic configuration

The USART is configured as follows:

- The USART block is enabled through the SYSAHBCLKCTRL register (see Table 19).
- The peripheral USART clock (PCLK), which is used by the USART baud rate generator, is controlled by the UARTCLKDIV register (see <u>Table 21</u>).

#### 12.3 Features

- 16-byte receive and transmit FIFOs.
- · Register locations conform to '550 industry standard.
- Receiver FIFO trigger points at 1, 4, 8, and 14 bytes.
- Built-in baud rate generator.
- Software or hardware flow control.
- RS-485/EIA-485 9-bit mode support with output enable.
- RTS/CTS flow control and other modem control signals.
- 1X-clock send or receive.
- ISO 7816-3 compliant smart card interface.
- IrDA support.

## 12.4 Pin description

Some of the following pins are not available in some packages.

#### Table 202. USART pin description

Pin	Type	Description
RXD	Input	Serial Input. Serial receive data.
TXD	Output	Serial Output. Serial transmit data (input/output in smart card mode).
RTS	Output	Request To Send. RS-485 direction control pin.
CTS	Input	Clear To Send.
DTR	Output	Data Terminal Ready.
DSR	Input	Data Set Ready.
DCD	Input	Data Carrier Detect.
RI	Input	Ring Indicator.
SCLK	I/O	Serial Clock.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

## 12.5 Register description

The USART contains registers organized as shown in <u>Table 203</u>. The Divisor Latch Access Bit (DLAB) is contained in LCR[7] and enables access to the Divisor Latches.

Offsets/addresses not shown in Table 203 are reserved.

Table 203. Register overview: USART (base address: 0x4000 8000)

Name	Access	Address offset	Description	Reset value[1]	Reference
RBR	RO	0x000	Receiver Buffer Register. Contains the next received character to be read. (DLAB=0)	NA	Table 204
THR	WO	0x000	Transmit Holding Register. The next character to be transmitted is written here. (DLAB=0)	NA	Table 205
DLL	R/W	0x000	Divisor Latch LSB. Least significant byte of the baud rate divisor value. The full divisor is used to generate a baud rate from the fractional rate divider. (DLAB=1)	0x01	Table 206
DLM	R/W	0x004	Divisor Latch MSB. Most significant byte of the baud rate divisor value. The full divisor is used to generate a baud rate from the fractional rate divider. (DLAB=1)	0	Table 207
IER	R/W	0x004	Interrupt Enable Register. Contains individual interrupt enable bits for the seven potential USART interrupts. (DLAB=0)	0	Table 208
IIR	RO	0x008	Interrupt ID Register. Identifies which interrupt(s) are pending.	0x01	Table 209
FCR	WO	0x008	FIFO Control Register. Controls USART FIFO usage and modes.	0	<u>Table 211</u>

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 203. Register overview: USART (base address: 0x4000 8000)

Name	Access	Address offset	Description	Reset value[1]	Reference
RS485ADRMATCH	R/W	0x050	RS-485/EIA-485 address match. Contains the address match value for RS-485/EIA-485 mode.	0	Table 228
RS485DLY	R/W	0x054	RS-485/EIA-485 direction control delay.	0	Table 229
SYNCCTRL	R/W	0x058	Synchronous mode control register.	0	Table 230

<sup>[1]</sup> Reset Value reflects the data stored in used bits only. It does not include reserved bits content.

## 12.5.1 USART Receiver Buffer Register (when DLAB = 0, Read Only)

The RBR is the top byte of the USART RX FIFO. The top byte of the RX FIFO contains the oldest character received and can be read via the bus interface. The LSB (bit 0) contains the first-received data bit. If the character received is less than 8 bits, the unused MSBs are padded with zeros.

The Divisor Latch Access Bit (DLAB) in the LCR must be zero in order to access the RBR. The RBR is always Read Only.

Since PE, FE and BI bits (see <u>Table 215</u>) correspond to the byte on the top of the RBR FIFO (i.e. the one that will be read in the next read from the RBR), the right approach for fetching the valid pair of received byte and its status bits is first to read the content of the LSR register, and then to read a byte from the RBR.

Table 204. USART Receiver Buffer Register when DLAB = 0, Read Only (RBR - address 0x4000 8000) bit description

Bit	Symbol	Description	Reset Value
7:0	RBR	The USART Receiver Buffer Register contains the oldest received byte in the USART RX FIFO.	undefined
31:8	-	Reserved	-

### 12.5.2 USART Transmitter Holding Register (when DLAB = 0, Write Only)

The THR is the top byte of the USART TX FIFO. The top byte is the newest character in the TX FIFO and can be written via the bus interface. The LSB represents the first bit to transmit.

The Divisor Latch Access Bit (DLAB) in the LCR must be zero in order to access the THR. The THR is always Write Only.

Table 205. USART Transmitter Holding Register when DLAB = 0, Write Only (THR - address 0x4000 8000) bit description

Bit	Symbol	Description	Reset Value
7:0	THR	Writing to the USART Transmit Holding Register causes the data to be stored in the USART transmit FIFO. The byte will be sent when it is the oldest byte in the FIFO and the transmitter is available.	NA
31:8	-	Reserved	-

**User manual** 

#### Chapter 12: LPC1315/16/17/45/46/47 USART

### 12.5.3 USART Divisor Latch LSB and MSB Registers (when DLAB = 1)

The USART Divisor Latch is part of the USART Baud Rate Generator and holds the value used (optionally with the Fractional Divider) to divide the UART\_PCLK clock in order to produce the baud rate clock, which must be the multiple of the desired baud rate that is specified by the Oversampling Register (typically 16X). The DLL and DLM registers together form a 16-bit divisor. DLL contains the lower 8 bits of the divisor and DLM contains the higher 8 bits. A zero value is treated like 0x0001. The Divisor Latch Access Bit (DLAB) in the LCR must be one in order to access the USART Divisor Latches. Details on how to select the right value for DLL and DLM can be found in Section 12.5.14.

Table 206. USART Divisor Latch LSB Register when DLAB = 1 (DLL - address 0x4000 8000) bit description

Bit	Symbol	Description	Reset value
7:0	DLLSB	The USART Divisor Latch LSB Register, along with the DLM register, determines the baud rate of the USART.	0x01
31:8	-	Reserved	-

Table 207. USART Divisor Latch MSB Register when DLAB = 1 (DLM - address 0x4000 8004) bit description

Bit	Symbol	Description	Reset value
7:0	DLMSB	The USART Divisor Latch MSB Register, along with the DLL register, determines the baud rate of the USART.	0x00
31:8	-	Reserved	-

### 12.5.4 USART Interrupt Enable Register (when DLAB = 0)

The IER is used to enable the various USART interrupt sources.

Table 208. USART Interrupt Enable Register when DLAB = 0 (IER - address 0x4000 8004) bit description

Bit	Symbol	Value	Description	Reset value
0	RBRINTEN		RBR Interrupt Enable. Enables the Receive Data Available interrupt. It also controls the Character Receive Time-out interrupt.	0
		0	Disable the RDA interrupt.	
	1 Enable the RDA interrupt.	Enable the RDA interrupt.		
1	THREINTEN		THRE Interrupt Enable. Enables the THRE interrupt. The status of this interrupt can be read from LSR[5].	0
		0	Disable the THRE interrupt.	
		1	Enable the THRE interrupt.	
2	RLSINTEN 0		Enables the Receive Line Status interrupt. The status of this interrupt can be read from LSR[4:1].	0
		0	Disable the RLS interrupt.	
		1	Enable the RLS interrupt.	
3	MSINTEN		Enables the Modem Status interrupt. The components of this interrupt can be read from the MSR.	0
		0	Disable the MS interrupt.	
		1	Enable the MS interrupt.

		1	Enable auto-baud time-out Interrupt.	
31:10	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 12.5.5 USART Interrupt Identification Register (Read Only)

IIR provides a status code that denotes the priority and source of a pending interrupt. The interrupts are frozen during a IIR access. If an interrupt occurs during a IIR access, the interrupt is recorded for the next IIR access.

Table 209. USART Interrupt Identification Register Read only (IIR - address 0x4004 8008) bit description

Bit	Symbol	Value	Description	Reset value
0	INTSTATUS		Interrupt status. Note that IIR[0] is active low. The pending interrupt can be determined by evaluating IIR[3:1].	1
		0	At least one interrupt is pending.	
		1	No interrupt is pending.	
3:1	3:1 INTID		Interrupt identification. IER[3:1] identifies an interrupt corresponding to the USART Rx FIFO. All other values of IER[3:1] not listed below are reserved.	0
		0x3	1 - Receive Line Status (RLS).	
		0x2	2a - Receive Data Available (RDA).	
		0x6	2b - Character Time-out Indicator (CTI).	
		0x1	3 - THRE Interrupt.	
		0x0	4 - Modem status	
5:4	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
7:6	FIFOEN		These bits are equivalent to FCR[0].	0
8	ABEOINT		End of auto-baud interrupt. True if auto-baud has finished successfully and interrupt is enabled.	0
9	ABTOINT		Auto-baud time-out interrupt. True if auto-baud has timed out and interrupt is enabled.	0
31:10	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Bits IIR[9:8] are set by the auto-baud function and signal a time-out or end of auto-baud condition. The auto-baud interrupt conditions are cleared by setting the corresponding Clear bits in the Auto-baud Control Register.

If the IntStatus bit is one and no interrupt is pending and the IntId bits will be zero. If the IntStatus is 0, a non auto-baud interrupt is pending in which case the IntId bits identify the type of interrupt and handling as described in <u>Table 210</u>. Given the status of IIR[3:0], an interrupt handler routine can determine the cause of the interrupt and how to clear the active interrupt. The IIR must be read in order to clear the interrupt prior to exiting the Interrupt Service Routine.

The USART RLS interrupt (IIR[3:1] = 011) is the highest priority interrupt and is set whenever any one of four error conditions occur on the USART RX input: overrun error (OE), parity error (PE), framing error (FE) and break interrupt (BI). The USART Rx error condition that set the interrupt can be observed via LSR[4:1]. The interrupt is cleared upon a LSR read.

The USART RDA interrupt (IIR[3:1] = 010) shares the second level priority with the CTI interrupt (IIR[3:1] = 110). The RDA is activated when the USART Rx FIFO reaches the trigger level defined in FCR7:6 and is reset when the USART Rx FIFO depth falls below the trigger level. When the RDA interrupt goes active, the CPU can read a block of data defined by the trigger level.

The CTI interrupt (IIR[3:1] = 110) is a second level interrupt and is set when the USART Rx FIFO contains at least one character and no USART Rx FIFO activity has occurred in 3.5 to 4.5 character times. Any USART Rx FIFO activity (read or write of USART RSR) will clear the interrupt. This interrupt is intended to flush the USART RBR after a message has been received that is not a multiple of the trigger level size. For example, if a 105 character message was to be sent and the trigger level was 10 characters, the CPU would receive 10 RDA interrupts resulting in the transfer of 100 characters and 1 to 5 CTI interrupts (depending on the service routine) resulting in the transfer of the remaining 5 characters.

Table 210. USART Interrupt Handling

IIR[3:0] value[1]	Priority	Interrupt type	Interrupt source	Interrupt reset
0001	-	None	None	-
0110	Highest	RX Line Status / Error	OE <sup>[2]</sup> or PE <sup>[2]</sup> or BI <sup>[2]</sup>	LSR Read <sup>[2]</sup>
0100	Second	RX Data Available	Rx data available or trigger level reached in FIFO (FCR0=1)	RBR Read <sup>[3]</sup> or USART FIFO drops below trigger level

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 210. USART Interrupt Handling

IIR[3:0] value[1]  Second Character Time-out indication  Character input or removed during a time period depending on how many characters are in FIFO and what the trigger level is set at (3.5 to 4.5 character times).  The exact time will be:  [(word length) × 7 - 2] × 8 + [(trigger level - number]	
character input or removed during a time period depending on how many characters are in FIFO and what the trigger level is set at (3.5 to 4.5 character times).  The exact time will be:	Interrupt reset
of characters) × 8 + 1] RCLKs	RBR Read <sup>[3]</sup>
0010 Third THRE THRE	IIR Read[4] (if source of interrupt) or THR write
0000 Fourth Modem CTS, DSR, RI, or DCD. Status	MSR Read

- [1] Values "0000", "0011", "0111", "1000", "1001", "1010", "1011", "1110", "1110", "1111" are reserved.
- [2] For details see Section 12.5.9 "USART Line Status Register (Read-Only)"
- [3] For details see Section 12.5.1 "USART Receiver Buffer Register (when DLAB = 0, Read Only)"
- [4] For details see Section 12.5.5 "USART Interrupt Identification Register (Read Only)" and Section 12.5.2 "USART Transmitter Holding Register (when DLAB = 0, Write Only)"

The USART THRE interrupt (IIR[3:1] = 001) is a third level interrupt and is activated when the USART THR FIFO is empty provided certain initialization conditions have been met. These initialization conditions are intended to give the USART THR FIFO a chance to fill up with data to eliminate many THRE interrupts from occurring at system start-up. The initialization conditions implement a one character delay minus the stop bit whenever THRE = 1 and there have not been at least two characters in the THR at one time since the last THRE = 1 event. This delay is provided to give the CPU time to write data to THR without a THRE interrupt to decode and service. A THRE interrupt is set immediately if the USART THR FIFO has held two or more characters at one time and currently, the THR is empty. The THRE interrupt is reset when a THR write occurs or a read of the IIR occurs and the THRE is the highest interrupt (IIR[3:1] = 001).

The modem status interrupt (IIR3:1 = 000) is the lowest priority USART interrupt and is activated whenever there is a state change on the CTS, DCD, or DSR or a trailing edge on the RI pin. The source of the modem interrupt can be read in MSR3:0. Reading the MSR clears the modem interrupt.

### 12.5.6 USART FIFO Control Register (Write Only)

The FCR controls the operation of the USART RX and TX FIFOs.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 211. USART FIFO Control Register Write only (FCR - address 0x4000 8008) bit description

Bit	Symbol	Value	Description	Reset value	
0	FIFOEN		FIFO enable	0	
		0	USART FIFOs are disabled. Must not be used in the application.		
		1	Active high enable for both USART Rx and TX FIFOs and FCR[7:1] access. This bit must be set for proper USART operation. Any transition on this bit will automatically clear the USART FIFOs.		
1	RXFIFO		RX FIFO Reset	0	
	RES	0	No impact on either of USART FIFOs.		
			1	Writing a logic 1 to FCR[1] will clear all bytes in USART Rx FIFO, reset the pointer logic. This bit is self-clearing.	
2	TXFIFO RES		TX FIFO Reset	0	
		RES	RES 0 N	No impact on either of USART FIFOs.	
				1	Writing a logic 1 to FCR[2] will clear all bytes in USART TX FIFO, reset the pointer logic. This bit is self-clearing.
3	-	-	Reserved	0	
5:4	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA	
7:6	RXTL		RX Trigger Level. These two bits determine how many USART FIFO characters must be received by the FIFO before an interrupt is activated.	0	
		0x0	Trigger level 0 (1 character or 0x01).		
		0x1	Trigger level 1 (4 characters or 0x04).		
		0x2	Trigger level 2 (8 characters or 0x08).		
		0x3	Trigger level 3 (14 characters or 0x0E).		
31:8	-	-	Reserved	-	

## 12.5.7 USART Line Control Register

The LCR determines the format of the data character that is to be transmitted or received.

Table 212. USART Line Control Register (LCR - address 0x4000 800C) bit description

Bit	Symbol	Value	Description	Reset Value
1:0	WLS		Word Length Select	0
		0x0	5-bit character length.	
		0x1	6-bit character length.	
		0x2	7-bit character length.	
		0x3	8-bit character length.	
2	SBS		Stop Bit Select	0
		0	1 stop bit.	
		1	2 stop bits (1.5 if LCR[1:0]=00).	

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 212. USART Line Control Register (LCR - address 0x4000 800C) bit description

Bit	Symbol	Value	Description	Reset Value
3	PE		Parity Enable	0
		0	Disable parity generation and checking.	
		1	Enable parity generation and checking.	
5:4	PS		Parity Select	0
		0x0	Odd parity. Number of 1s in the transmitted character and the attached parity bit will be odd.	
		0x1	Even Parity. Number of 1s in the transmitted character and the attached parity bit will be even.	
		0x2	Forced 1 stick parity.	
		0x3	Forced 0 stick parity.	
6	BC		Break Control	0
		0	Disable break transmission.	
		1	Enable break transmission. Output pin USART TXD is forced to logic 0 when LCR[6] is active high.	
7	DLAB		Divisor Latch Access Bit	0
		0	Disable access to Divisor Latches.	
		1	Enable access to Divisor Latches.	
31:8	-	-	Reserved	-

## 12.5.8 USART Modem Control Register

The MCR enables the modem loopback mode and controls the modem output signals.

Table 213. USART Modem Control Register (MCR - address 0x4000 8010) bit description

Bit	Symbol	Value	Description	Reset value
0	DTRCTRL		Source for modem output pin $\overline{\text{DTR}}$ . This bit reads as 0 when modem loopback mode is active.	0
1	RTSCTRL		Source for modem output pin $\overline{\text{RTS}}$ . This bit reads as 0 when modem loopback mode is active.	0
3:2	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0
4	LMS		Loopback Mode Select. The modem loopback mode provides a mechanism to perform diagnostic loopback testing. Serial data from the transmitter is connected internally to serial input of the receiver. Input pin, RXD, has no effect on loopback and output pin, TXD is held in marking state. The DSR, CTS, DCD, and RI pins are ignored. Externally, DTR and RTS are set inactive. Internally, the upper four bits of the MSR are driven by the lower four bits of the MCR. This permits modem status interrupts to be generated in loopback mode by writing the lower four bits of MCR.	0
		0	Disable modem loopback mode.	
		1	Enable modem loopback mode.	
5	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 213. USART Modem Control Register (MCR - address 0x4000 8010) bit description

Bit	Symbol	Value	Description	Reset value
6	RTSEN		RTS enable	0
		0	Disable auto-rts flow control.	
		1	Enable auto-rts flow control.	
7	CTSEN		CTS enable	0
		0	Disable auto-cts flow control.	
		1	Enable auto-cts flow control.	
31:8	-	-	Reserved	-

#### 12.5.8.1 Auto-flow control

If auto-RTS mode is enabled, the USART's receiver FIFO hardware controls the RTS output of the USART. If the auto-CTS mode is enabled, the USART's transmitter will only start sending if the CTS pin is low.

#### 12.5.8.1.1 **Auto-RTS**

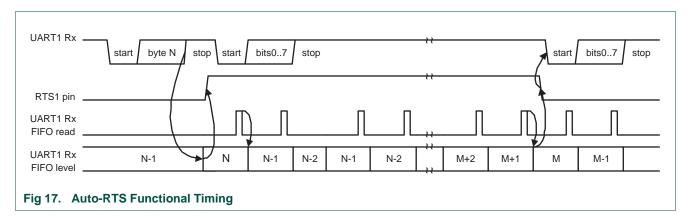

The auto-RTS function is enabled by setting the RTSen bit. Auto-RTS data flow control originates in the RBR module and is linked to the programmed receiver FIFO trigger level. If auto-RTS is enabled, the data-flow is controlled as follows:

When the receiver FIFO level reaches the programmed trigger level, RTS is deasserted (to a high value). It is possible that the sending USART sends an additional byte after the trigger level is reached (assuming the sending USART has another byte to send) because it might not recognize the deassertion of RTS until after it has begun sending the additional byte. RTS is automatically reasserted (to a low value) once the receiver FIFO has reached the previous trigger level. The reassertion of RTS signals the sending USART to continue transmitting data.

If Auto-RTS mode is disabled, the RTSen bit controls the RTS output of the USART. If Auto-RTS mode is enabled, hardware controls the RTS output, and the actual value of RTS will be copied in the RTS Control bit of the USART. As long as Auto-RTS is enabled, the value of the RTS Control bit is read-only for software.

Example: Suppose the USART operating in type '550 mode has the trigger level in FCR set to 0x2, then, if Auto-RTS is enabled, the USART will deassert the RTS output as soon as the receive FIFO contains 8 bytes (Table 211 on page 215). The RTS output will be reasserted as soon as the receive FIFO hits the previous trigger level: 4 bytes.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

#### 12.5.8.1.2 Auto-CTS

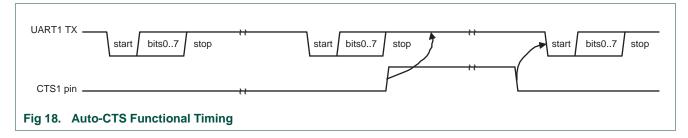

The Auto-CTS function is enabled by setting the CTSen bit. If Auto-CTS is enabled, the transmitter circuitry checks the CTS input before sending the next data byte. When CTS is active (low), the transmitter sends the next byte. To stop the transmitter from sending the following byte, CTS must be released before the middle of the last stop bit that is currently being sent. In Auto-CTS mode, a change of the CTS signal does not trigger a modem status interrupt unless the CTS Interrupt Enable bit is set, but the Delta CTS bit in the MSR will be set. Table 214 lists the conditions for generating a Modem Status interrupt.

Table 214. Modem status interrupt generation

Enable modem status interrupt (IER[3])	CTSen (MCR[7])	CTS interrupt enable (IER[7])	Delta CTS (MSR[0])	Delta DCD or trailing edge RI or Delta DSR (MSR[3:1])	Modem status interrupt
0	X	X	X	X	No
1	0	Х	0	0	No
1	0	Х	1	X	Yes
1	0	Х	Х	1	Yes
1	1	0	Х	0	No
1	1	0	Х	1	Yes
1	1	1	0	0	No
1	1	1	1	Х	Yes
1	1	1	Х	1	Yes

The auto-CTS function typically eliminates the need for CTS interrupts. When flow control is enabled, a  $\overline{\text{CTS}}$  state change does not trigger host interrupts because the device automatically controls its own transmitter. Without Auto-CTS, the transmitter sends any data present in the transmit FIFO and a receiver overrun error can result. Figure 18 illustrates the Auto-CTS functional timing.

## Chapter 12: LPC1315/16/17/45/46/47 USART

During transmission of the second character the  $\overline{\text{CTS}}$  signal is negated. The <u>third</u> character is not sent thereafter. The USART maintains 1 on TXD as long as  $\overline{\text{CTS}}$  is negated (high). As soon as  $\overline{\text{CTS}}$  is asserted, transmission resumes and a start bit is sent followed by the data bits of the next character.

## 12.5.9 USART Line Status Register (Read-Only)

The LSR is a read-only register that provides status information on the USART TX and RX blocks.

Table 215. USART Line Status Register Read only (LSR - address 0x4000 8014) bit description

Bit	Symbol	Value	Description	Reset Value
0	RDR		Receiver Data Ready:LSR[0] is set when the RBR holds an unread character and is cleared when the USART RBR FIFO is empty.	0
		0	RBR is empty.	
		1	RBR contains valid data.	
1	1 OE		Overrun Error. The overrun error condition is set as soon as it occurs. A LSR read clears LSR[1]. LSR[1] is set when USART RSR has a new character assembled and the USART RBR FIFO is full. In this case, the USART RBR FIFO will not be overwritten and the character in the USART RSR will be lost.	0
		0	Overrun error status is inactive.	
		1	Overrun error status is active.	
2	PE		Parity Error. When the parity bit of a received character is in the wrong state, a parity error occurs. A LSR read clears LSR[2]. Time of parity error detection is dependent on FCR[0].	0
			<b>Note:</b> A parity error is associated with the character at the top of the USART RBR FIFO.	
		0	Parity error status is inactive.	
		1	Parity error status is active.	

219 of 416

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 215. USART Line Status Register Read only (LSR - address 0x4000 8014) bit description ...continued

descriptioncontinued					
Bit	Symbol	Value	Description	Reset Value	
3	FE		Framing Error. When the stop bit of a received character is a logic 0, a framing error occurs. A LSR read clears LSR[3]. The time of the framing error detection is dependent on FCR0. Upon detection of a framing error, the RX will attempt to re-synchronize to the data and assume that the bad stop bit is actually an early start bit. However, it cannot be assumed that the next received byte will be correct even if there is no Framing Error.	0	
			<b>Note:</b> A framing error is associated with the character at the top of the USART RBR FIFO.		
		0	Framing error status is inactive.		
		1	Framing error status is active.		
4	ВІ		Break Interrupt. When RXD1 is held in the spacing state (all zeros) for one full character transmission (start, data, parity, stop), a break interrupt occurs. Once the break condition has been detected, the receiver goes idle until RXD1 goes to marking state (all ones). A LSR read clears this status bit. The time of break detection is dependent on FCR[0].	0	
			<b>Note:</b> The break interrupt is associated with the character at the top of the USART RBR FIFO.		
		0	Break interrupt status is inactive.		
		1	Break interrupt status is active.		
5	THRE		Transmitter Holding Register Empty. THRE is set immediately upon detection of an empty USART THR and is cleared on a THR write.	1	
		0	THR contains valid data.		
		1	THR is empty.		
6	TEMT		Transmitter Empty. TEMT is set when both THR and TSR are empty; TEMT is cleared when either the TSR or the THR contain valid data.	1	
		0	THR and/or the TSR contains valid data.		
		1	THR and the TSR are empty.		
7	RXFE		Error in RX FIFO. LSR[7] is set when a character with a RX error such as framing error, parity error or break interrupt, is loaded into the RBR. This bit is cleared when the LSR register is read and there are no subsequent errors in the USART FIFO.	0	
		0	RBR contains no USART RX errors or FCR[0]=0.		
		1	USART RBR contains at least one USART RX error.		
8	TXERR		Tx Error. In smart card T=0 operation, this bit is set when the smart card has NACKed a transmitted character, one more than the number of times indicated by the TXRETRY field.	0	
31:9	-	-	Reserved	-	
	-				

## Chapter 12: LPC1315/16/17/45/46/47 USART

## 12.5.10 USART Modem Status Register

The MSR is a read-only register that provides status information on USART input signals. Bit 0 is cleared when (after) this register is read.

Table 216: USART Modem Status Register (MSR - address 0x4000 8018) bit description

			Reset value
0 DCTS		Delta CTS. Set upon state change of input CTS. Cleared on an MSR read.	0
	0	No change detected on modem input, CTS.	
	1	State change detected on modem input, CTS.	
1 DDSR		Delta DSR. Set upon state change of input DSR. Cleared on an MSR read.	0
	0	No change detected on modem input, DSR.	
	1	State change detected on modem input, DSR.	
2 TERI		Trailing Edge RI. Set upon low to high transition of input RI. Cleared on an MSR read.	0
	0	No change detected on modem input, RI.	
	1	Low-to-high transition detected on RI.	
3 DDCD		Delta DCD. Set upon state change of input DCD. Cleared on an MSR read.	0
	0	No change detected on modem input, DCD.	
	1	State change detected on modem input, DCD.	
4 CTS	-	Clear To Send State. Complement of input signal CTS. This bit is connected to MCR[1] in modem loopback mode.	0
5 DSR	-	Data Set Ready State. Complement of input signal DSR. This bit is connected to MCR[0] in modem loopback mode.	0
6 RI	-	Ring Indicator State. Complement of input RI. This bit is connected to MCR[2] in modem loopback mode.	0
7 DCD	-	Data Carrier Detect State. Complement of input DCD. This bit is connected to MCR[3] in modem loopback mode.	0
31:8 -	-	Reserved, the value read from a reserved bit is not defined.	NA

## 12.5.11 USART Scratch Pad Register

The SCR has no effect on the USART operation. This register can be written and/or read at user's discretion. There is no provision in the interrupt interface that would indicate to the host that a read or write of the SCR has occurred.

Table 217. USART Scratch Pad Register (SCR - address 0x4000 801C) bit description

Bit	Symbol	Description	Reset Value
7:0	PAD	A readable, writable byte.	0x00
31:8	-	Reserved	-

#### Chapter 12: LPC1315/16/17/45/46/47 USART

## 12.5.12 USART Auto-baud Control Register

The USART Auto-baud Control Register (ACR) controls the process of measuring the incoming clock/data rate for baud rate generation, and can be read and written at the user's discretion.

Table 218. USART Auto-baud Control Register (ACR - address 0x4000 8020) bit description

Bit	Symbol	Value	Description	Reset value
0	START		This bit is automatically cleared after auto-baud completion.	0
		0	Auto-baud stop (auto-baud is not running).	
		1	Auto-baud start (auto-baud is running). Auto-baud run bit. This bit is automatically cleared after auto-baud completion.	
1	1 MODE		Auto-baud mode select bit.	0
			Mode 0.	
		1	Mode 1.	
2	AUTORESTART		Start mode	0
		0	No restart	
		1	Restart in case of time-out (counter restarts at next USART Rx falling edge)	
7:3	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0
8	ABEOINTCLR		End of auto-baud interrupt clear bit (write only accessible).	0
		0	Writing a 0 has no impact.	
		1	Writing a 1 will clear the corresponding interrupt in the IIR.	
9	ABTOINTCLR		Auto-baud time-out interrupt clear bit (write only accessible).	0
		0	Writing a 0 has no impact.	
		1	Writing a 1 will clear the corresponding interrupt in the IIR.	
31:10	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0

#### 12.5.12.1 Auto-baud

The USART auto-baud function can be used to measure the incoming baud rate based on the "AT" protocol (Hayes command). If enabled the auto-baud feature will measure the bit time of the receive data stream and set the divisor latch registers DLM and DLL accordingly.

Auto-baud is started by setting the ACR Start bit. Auto-baud can be stopped by clearing the ACR Start bit. The Start bit will clear once auto-baud has finished and reading the bit will return the status of auto-baud (pending/finished).

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Two auto-baud measuring modes are available which can be selected by the ACR Mode bit. In Mode 0 the baud rate is measured on two subsequent falling edges of the USART Rx pin (the falling edge of the start bit and the falling edge of the least significant bit). In Mode 1 the baud rate is measured between the falling edge and the subsequent rising edge of the USART Rx pin (the length of the start bit).

The ACR AutoRestart bit can be used to automatically restart baud rate measurement if a time-out occurs (the rate measurement counter overflows). If this bit is set, the rate measurement will restart at the next falling edge of the USART Rx pin.

The auto-baud function can generate two interrupts.

- The IIR ABTOInt interrupt will get set if the interrupt is enabled (IER ABToIntEn is set and the auto-baud rate measurement counter overflows).
- The IIR ABEOInt interrupt will get set if the interrupt is enabled (IER ABEOIntEn is set and the auto-baud has completed successfully).

The auto-baud interrupts have to be cleared by setting the corresponding ACR ABTOIntCIr and ABEOIntEn bits.

The fractional baud rate generator must be disabled (DIVADDVAL = 0) during auto-baud. Also, when auto-baud is used, any write to DLM and DLL registers should be done before ACR register write. The minimum and the maximum baud rates supported by USART are a function of USART\_PCLK and the number of data bits, stop bits and parity bits.

$$ratemin = \frac{2 \times PCLK}{16 \times 2^{15}} \le UART_{baudrate} \le \frac{PCLK}{16 \times (2 + databits + paritybits + stopbits)} = ratemax$$
 (2)

#### 12.5.12.2 Auto-baud modes

When the software is expecting an "AT" command, it configures the USART with the expected character format and sets the ACR Start bit. The initial values in the divisor latches DLM and DLM don't care. Because of the "A" or "a" ASCII coding ("A" = 0x41, "a" = 0x61), the USART Rx pin sensed start bit and the LSB of the expected character are delimited by two falling edges. When the ACR Start bit is set, the auto-baud protocol will execute the following phases:

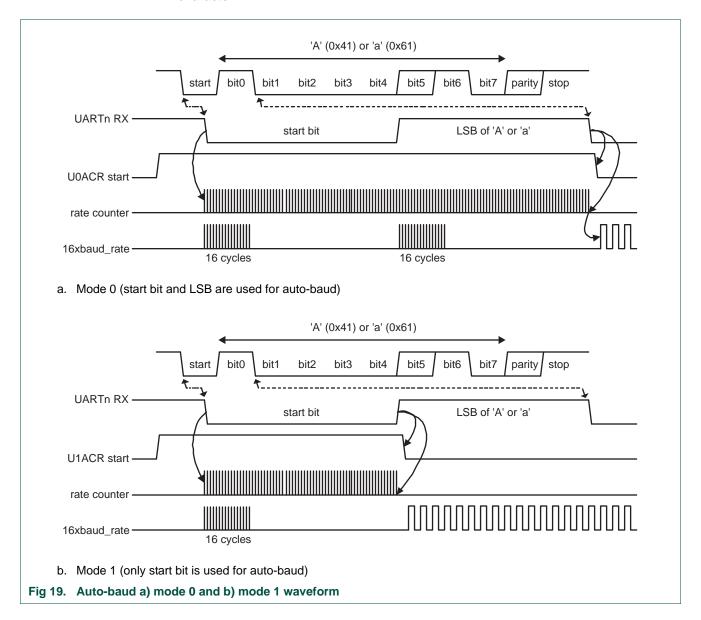

- 1. On ACR Start bit setting, the baud rate measurement counter is reset and the USART RSR is reset. The RSR baud rate is switched to the highest rate.
- 2. A falling edge on USART Rx pin triggers the beginning of the start bit. The rate measuring counter will start counting UART\_PCLK cycles.
- During the receipt of the start bit, 16 pulses are generated on the RSR baud input with the frequency of the USART input clock, guaranteeing the start bit is stored in the RSR.
- During the receipt of the start bit (and the character LSB for Mode = 0), the rate counter will continue incrementing with the pre-scaled USART input clock (UART\_PCLK).
- 5. If Mode = 0, the rate counter will stop on next falling edge of the USART Rx pin. If Mode = 1, the rate counter will stop on the next rising edge of the USART Rx pin.

UM10524 **NXP Semiconductors** 

## Chapter 12: LPC1315/16/17/45/46/47 USART

6. The rate counter is loaded into DLM/DLL and the baud rate will be switched to normal operation. After setting the DLM/DLL, the end of auto-baud interrupt IIR ABEOInt will be set, if enabled. The RSR will now continue receiving the remaining bits of the character.

## 12.5.13 USART IrDA Control Register

The IrDA Control Register enables and configures the IrDA mode. The value of the ICR should not be changed while transmitting or receiving data, or data loss or corruption may occur.

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 219: USART IrDA Control Register (ICR - 0x4000 8024) bit description

Bit	Symbol	Value	Description	Reset value			
0	IRDAEN		IrDA mode enable	0			
			IrDA mode is disabled.				
		1	IrDA mode is enabled.				
1	IRDAINV		Serial input inverter	0			
		O The serial input is not inverted.					
		1	The serial input is inverted. This has no effect on the serial output.				
2	2 FIXPULSEEN		IrDA fixed pulse width mode.	0			
		0	IrDA fixed pulse width mode disabled.				
		1	IrDA fixed pulse width mode enabled.				
5:3	PULSEDIV		Configures the pulse width when FixPulseEn = 1.	0			
		0x0	3 / (16 × baud rate)				
		0x1	$2 \times T_{PCLK}$				
		0x2	4 × T <sub>PCLK</sub>				
		0x3	8 × T <sub>PCLK</sub>				
		0x4	16 × T <sub>PCLK</sub>				
		0x5	32 × T <sub>PCLK</sub>				
		0x6	64 × T <sub>PCLK</sub>				
		0x7	128 × T <sub>PCLK</sub>				
31:6	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0			

The PulseDiv bits in the ICR are used to select the pulse width when the fixed pulse width mode is used in IrDA mode (IrDAEn = 1 and FixPulseEn = 1). The value of these bits should be set so that the resulting pulse width is at least 1.63  $\mu$ s. Table 220 shows the possible pulse widths.

Table 220: IrDA Pulse Width

FixPulseEn	PulseDiv	IrDA Transmitter Pulse width (μs)
0	Х	3 / (16 × baud rate)
1	0	2 × T <sub>PCLK</sub>
1	1	4 × T <sub>PCLK</sub>
1	2	8 × T <sub>PCLK</sub>
1	3	16 × T <sub>PCLK</sub>
1	4	$32 \times T_{PCLK}$
1	5	64 × T <sub>PCLK</sub>
1	6	128 × T <sub>PCLK</sub>
1	7	256 × T <sub>PCLK</sub>

#### Chapter 12: LPC1315/16/17/45/46/47 USART

## 12.5.14 USART Fractional Divider Register

The USART Fractional Divider Register (FDR) controls the clock pre-scaler for the baud rate generation and can be read and written at the user's discretion. This pre-scaler takes the APB clock and generates an output clock according to the specified fractional requirements.

Important: If the fractional divider is active (DIVADDVAL > 0) and DLM = 0, the value of the DLL register must be 3 or greater.

Table 221. USART Fractional Divider Register (FDR - address 0x4000 8028) bit description

Bit	Function	Description	Reset value
3:0	DIVADDVAL	Baud rate generation pre-scaler divisor value. If this field is 0, fractional baud rate generator will not impact the USART baud rate.	0
7:4	MULVAL	Baud rate pre-scaler multiplier value. This field must be greater or equal 1 for USART to operate properly, regardless of whether the fractional baud rate generator is used or not.	1
31:8	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	0

This register controls the clock pre-scaler for the baud rate generation. The reset value of the register keeps the fractional capabilities of USART disabled making sure that USART is fully software and hardware compatible with USARTs not equipped with this feature.

The USART baud rate can be calculated as:

$$UART_{baudrate} = \frac{PCLK}{16 \times (256 \times U0DLM + U0DLL) \times \left(1 + \frac{DivAddVal}{MulVal}\right)}$$
(3)

Where UART PCLK is the peripheral clock, DLM and DLL are the standard USART baud rate divider registers, and DIVADDVAL and MULVAL are USART fractional baud rate generator specific parameters.

The value of MULVAL and DIVADDVAL should comply to the following conditions:

- 1.  $1 \le MULVAL \le 15$
- 2.  $0 \le DIVADDVAL \le 14$
- 3. DIVADDVAL< MULVAL

The value of the FDR should not be modified while transmitting/receiving data or data may be lost or corrupted.

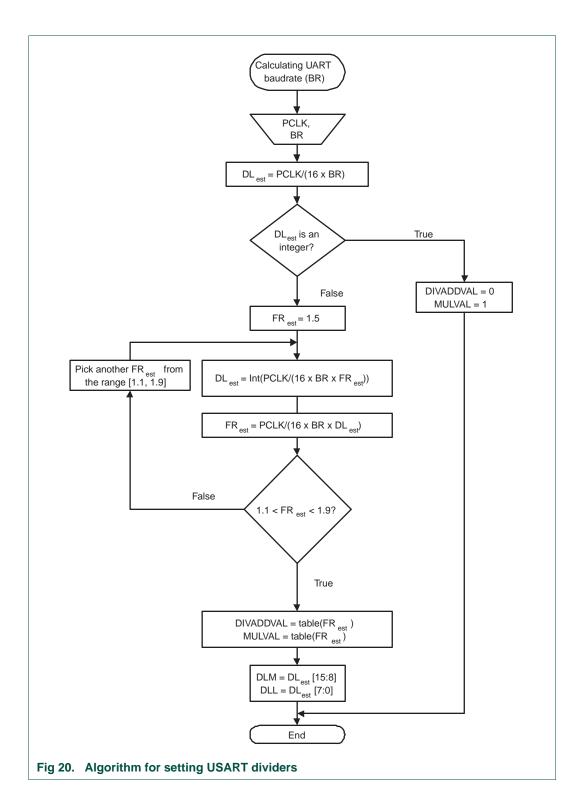

If the FDR register value does not comply to these two requests, then the fractional divider output is undefined. If DIVADDVAL is zero then the fractional divider is disabled, and the clock will not be divided.

### Chapter 12: LPC1315/16/17/45/46/47 USART

#### 12.5.14.1 Baud rate calculation

The USART can operate with or without using the Fractional Divider. In real-life applications it is likely that the desired baud rate can be achieved using several different Fractional Divider settings. The following algorithm illustrates one way of finding a set of DLM, DLL, MULVAL, and DIVADDVAL values. Such a set of parameters yields a baud rate with a relative error of less than 1.1% from the desired one.

Table 222. Fractional Divider setting look-up table

#### 12.5.14.1.1 Example 1: UART PCLK = 14.7456 MHz, BR = 9600

According to the provided algorithm  $DL_{est} = PCLK/(16 \text{ x BR}) = 14.7456 \text{ MHz} / (16 \text{ x 9600}) = 96$ . Since this  $DL_{est}$  is an integer number, DIVADDVAL = 0, MULVAL = 1, DLM = 0, and DLL = 96.

#### 12.5.14.1.2 Example 2: UART\_PCLK = 12.0 MHz, BR = 115200

According to the provided algorithm  $DL_{est} = PCLK/(16 \text{ x BR}) = 12 \text{ MHz} / (16 \text{ x } 115200) = 6.51$ . This  $DL_{est}$  is not an integer number and the next step is to estimate the FR parameter. Using an initial estimate of  $FR_{est} = 1.5$  a new  $DL_{est} = 4$  is calculated and  $FR_{est}$  is recalculated as  $FR_{est} = 1.628$ . Since FRest = 1.628 is within the specified range of 1.1 and 1.9, DIVADDVAL and MULVAL values can be obtained from the attached look-up table.

The closest value for FRest = 1.628 in the look-up <u>Table 222</u> is FR = 1.625. It is equivalent to DIVADDVAL = 5 and MULVAL = 8.

Based on these findings, the suggested USART setup would be: DLM = 0, DLL = 4, DIVADDVAL = 5, and MULVAL = 8. According to Equation 3, the USART's baud rate is 115384. This rate has a relative error of 0.16% from the originally specified 115200.

### 12.5.15 USART Oversampling Register

In most applications, the USART samples received data 16 times in each nominal bit time, and sends bits that are 16 input clocks wide. This register allows software to control the ratio between the input clock and bit clock. This is required for smart card mode, and provides an alternative to fractional division for other modes.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 223. USART Oversampling Register (OSR - address 0x4000 802C) bit description

Bit	Symbol	Description	Reset value
0	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
3:1	OSFRAC	Fractional part of the oversampling ratio, in units of $1/8$ th of an input clock period. (001 = 0.125,, 111 = 0.875)	0
7:4	OSINT	Integer part of the oversampling ratio, minus 1. The reset values equate to the normal operating mode of 16 input clocks per bit time.	0xF
14:8	FDINT	In Smart Card mode, these bits act as a more-significant extension of the OSint field, allowing an oversampling ratio up to 2048 as required by ISO7816-3. In Smart Card mode, bits 14:4 should initially be set to 371, yielding an oversampling ratio of 372.	0
31:15	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

**Example:** For a baud rate of 3.25 Mbps with a 24 MHz USART clock frequency, the ideal oversampling ratio is 24/3.25 or 7.3846. Setting OSINT to 0110 for 7 clocks/bit and OSFrac to 011 for 0.375 clocks/bit, results in an oversampling ratio of 7.375.

In Smart card mode, OSInt is extended by FDINT. This extends the possible oversampling to 2048, as required to support ISO 7816-3. Note that this value can be exceeded when D<0, but this is not supported by the USART. When Smart card mode is enabled, the initial value of OSINT and FDINT should be programmed as "00101110011" (372 minus one).

### 12.5.16 USART Transmit Enable Register

In addition to being equipped with full hardware flow control (auto-cts and auto-rts mechanisms described above), TER enables implementation of software flow control. When TxEn = 1, the USART transmitter will keep sending data as long as they are available. As soon as TxEn becomes 0, USART transmission will stop.

Although <u>Table 224</u> describes how to use TxEn bit in order to achieve hardware flow control, it is strongly suggested to let the USART hardware implemented auto flow control features take care of this and limit the scope of TxEn to software flow control.

Table 224 describes how to use TXEn bit in order to achieve software flow control.

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 224. USART Transmit Enable Register (TER - address 0x4000 8030) bit description

Bit	Symbol	Description	Reset Value
6:0	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
7	TXEN	When this bit is 1, as it is after a Reset, data written to the THR is output on the TXD pin as soon as any preceding data has been sent. If this bit cleared to 0 while a character is being sent, the transmission of that character is completed, but no further characters are sent until this bit is set again. In other words, a 0 in this bit blocks the transfer of characters from the THR or TX FIFO into the transmit shift register. Software can clear this bit when it detects that the a hardware-handshaking TX-permit signal (CTS) has gone false, or with software handshaking, when it receives an XOFF character (DC3). Software can set this bit again when it detects that the TX-permit signal has gone true, or when it receives an XON (DC1) character.	1
31:8	-	Reserved	-

## 12.5.17 USART Half-duplex enable register

**Remark:** The HDEN register should be disabled when in smart card mode or IrDA mode (smart card and IrDA by default run in half-duplex mode).

After reset the USART will be in full-duplex mode, meaning that both TX and RX work independently. After setting the HDEN bit, the USART will be in half-duplex mode. In this mode, the USART ensures that the receiver is locked when idle, or will enter a locked state after having received a complete ongoing character reception. Line conflicts must be handled in software. The behavior of the USART is unpredictable when data is presented for reception while data is being transmitted.

For this reason, the value of the HDEN register should not be modified while sending or receiving data, or data may be lost or corrupted.

Table 225. USART Half duplex enable register (HDEN - addresses 0x4000 8040) bit description

Bit	Symbol	Value	Description	Reset value
0	HDEN	HDEN Half-duplex mode enable	Half-duplex mode enable	0
		0	Disable half-duplex mode.	
		1	Enable half-duplex mode.	
31:1	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-

## 12.5.18 USART Smart Card Interface Control register

This register allows the USART to be used in asynchronous smart card applications.

231 of 416

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 226. USART Smart Card Interface Control register (SCICTRL - address 0x4000 8048) bit description

Bit	Symbol	Value	Description	Reset value
0	SCIEN		Smart Card Interface Enable.	0
		0	Smart card interface disabled.	
		1	Asynchronous half duplex smart card interface is enabled.	
1	NACKDIS		NACK response disable. Only applicable in T=0.	0
		0	A NACK response is enabled.	
		1	A NACK response is inhibited.	
2	PROTSEL		Protocol selection as defined in the ISO7816-3 standard.	0
		0	T = 0	
		1	T = 1	
4:3	-	-	Reserved.	-
7:5	TXRETRY	-	When the protocol selection T bit (above) is 0, the field controls the maximum number of retransmissions that the USART will attempt if the remote device signals NACK. When NACK has occurred this number of times plus one, the Tx Error bit in the LSR is set, an interrupt is requested if enabled, and the USART is locked until the FIFO is cleared.	-
15:8	XTRAGUARD	-	When the protocol selection T bit (above) is 0, this field indicates the number of bit times (ETUs) by which the guard time after a character transmitted by the USART should exceed the nominal 2 bit times. 0xFF in this field may indicate that there is just a single bit after a character and 11 bit times/character	
31:16	-	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 12.5.19 USART RS485 Control register

The RS485CTRL register controls the configuration of the USART in RS-485/EIA-485 mode.

Table 227. USART RS485 Control register (RS485CTRL - address 0x4000 804C) bit description

Bit	Symbol	Value	Description	Reset value
0	NMMEN		NMM enable.	0
		0	RS-485/EIA-485 Normal Multidrop Mode (NMM) is disabled.	0
		1	RS-485/EIA-485 Normal Multidrop Mode (NMM) is enabled. In this mode, an address is detected when a received byte causes the USART to set the parity error and generate an interrupt.	

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 227. USART RS485 Control register (RS485CTRL - address 0x4000 804C) bit description ...continued

Bit	Symbol	Value	Description	Reset value

		1	Auto Address Detect (AAD) is enabled.	
3 S	SEL		Select direction control pin	0
		0	$\frac{\text{If direction control is enabled (bit DCTRL = 1), pin}}{\text{RTS}} \text{ is used for direction control.}$	
		1	If direction control is enabled (bit DCTRL = 1), pin $\overline{DTR}$ is used for direction control.	
4	DCTRL		Auto direction control enable.	0
		0 Disable Auto Direction Control.	Disable Auto Direction Control.	
		1	Enable Auto Direction Control.	
5	OINV		Polarity control. This bit reverses the polarity of the direction control signal on the RTS (or DTR) pin.	0
		0	The direction control pin will be driven to logic 0 when the transmitter has data to be sent. It will be driven to logic 1 after the last bit of data has been transmitted.	
		1	The direction control pin will be driven to logic 1 when the transmitter has data to be sent. It will be driven to logic 0 after the last bit of data has been transmitted.	
31:6	-	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 12.5.20 USART RS-485 Address Match register

The RS485ADRMATCH register contains the address match value for RS-485/EIA-485 mode.

Table 228. USART RS-485 Address Match register (RS485ADRMATCH - address 0x4000 8050) bit description

Bit	Symbol	Description	Reset value
7:0	ADRMATCH	Contains the address match value.	0x00
31:8	-	Reserved	-

## 12.5.21 USART RS-485 Delay value register

The user may program the 8-bit RS485DLY register with a delay between the last stop bit leaving the TXFIFO and the de-assertion of  $\overline{\text{RTS}}$  (or  $\overline{\text{DTR}}$ ). This delay time is in periods of the baud clock. Any delay time from 0 to 255 bit times may be programmed.

## Chapter 12: LPC1315/16/17/45/46/47 USART

Table 229. USART RS-485 Delay value register (RS485DLY - address 0x4000 8054) bit description

Bit	Symbol	Description	Reset value
7:0	DLY	Contains the direction control (RTS or DTR) delay value. This register works in conjunction with an 8-bit counter.	0x00
31:8	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 12.5.22 USART Synchronous mode control register

SYNCCTRL register controls the synchronous mode. When this mode is in effect, the USART generates or receives a bit clock on the SCLK pin and applies it to the transmit and receive shift registers. Synchronous mode should not be used with smart card mode.

Table 230. USART Synchronous mode control register (SYNCCTRL - address 0x4000 8058) bit description

Bit	Symbol	Value	Description	Reset value
0	SYNC		Enables synchronous mode.	0
		0	Disabled	
		1	Enabled	
1	CSRC		Clock source select.	0
		0	Synchronous slave mode (SCLK in)	
		1	Synchronous master mode (SCLK out)	
2	FES		Falling edge sampling.	0
		0	RxD is sampled on the rising edge of SCLK	
		1	RxD is sampled on the falling edge of SCLK	
3	TSBYPASS		Transmit synchronization bypass in synchronous slave mode.	0
		0	The input clock is synchronized prior to being used in clock edge detection logic.	
		1	The input clock is not synchronized prior to being used in clock edge detection logic. This allows for a high er input clock rate at the expense of potential metastability.	
4	CSCEN		Continuous master clock enable (used only when CSRC is 1)	0
		0	SCLK cycles only when characters are being sent on TxD	
		1	SCLK runs continuously (characters can be received on RxD independently from transmission on TxD)	
5	SSDIS		Start/stop bits	0
		0	Send start and stop bits as in other modes.	
		1	Do not send start/stop bits.	

#### Chapter 12: LPC1315/16/17/45/46/47 USART

Table 230. USART Synchronous mode control register (SYNCCTRL - address 0x4000 8058) bit description

Bit	Symbol	Value	Description	Reset value
6	CCCLR		Continuous clock clear	0
		0	CSCEN is under software control.	
		<ol> <li>Hardware clears CSCEN after each of received.</li> </ol>	Hardware clears CSCEN after each character is received.	
31:7	-		Reserved. The value read from a reserved bit is not defined.	NA

After reset, synchronous mode is disabled. Synchronous mode is enabled by setting the SYNC bit. When SYNC is 1, the USART operates as follows:

- The CSRC bit controls whether the USART sends (master mode) or receives (slave mode) a serial bit clock on the SCLK pin.
- When CSRC is 1 selecting master mode, the CSCEN bit selects whether the USART produces clocks on SCLK continuously (CSCEN=1) or only when transmit data is being sent on TxD (CSCEN=0).
- 3. The SSDIS bit controls whether start and stop bits are used. When SSDIS is 0, the USART sends and samples for start and stop bits as in other modes. When SSDIS is 1, the USART neither sends nor samples for start or stop bits, and each falling edge on SCLK samples a data bit on RxD into the receive shift register, as well as shifting the transmit shift register.

The rest of this section provides further details of operation when SYNC is 1.

Data changes on TxD from falling edges on SCLK. When SSDIS is 0, the FES bit controls whether the USART samples serial data on RxD on rising edges or falling edges on SCLK. When SSDIS is 1, the USART ignores FES and always samples RxD on falling edges on SCLK.

The combination SYNC=1, CSRC=1, CSCEN=1, and SSDIS=1 is a difficult operating mode, because SCLK applies to both directions of data flow and there is no defined mechanism to signal the receivers when valid data is present on TxD or RxD.

Lacking such a mechanism, SSDIS=1 can be used with CSCEN=0 or CSRC=0 in a mode similar to the SPI protocol, in which characters are (at least conceptually) "exchanged" between the USART and remote device for each set of 8 clock cycles on SCLK. Such operation can be called full-duplex, but the same hardware mode can be used in a half-duplex way under control of a higher-layer protocol, in which the source of SCLK toggles it in groups of N cycles whenever data is to be sent in either direction. (N being the number of bits/character.)

When the LPC1315/16/17/45/46/47 USART is the clock source (CSRC=1), such half-duplex operation can lead to the rather artificial-seeming requirement of writing a dummy character to the Transmitter Holding Register in order to generate 8 clocks so that a character can be received. The CCCLR bit provides a more natural way of programming half-duplex reception. When the higher-layer protocol dictates that the LPC1315/16/17/45/46/47 USART should receive a character, software should write the

#### Chapter 12: LPC1315/16/17/45/46/47 USART

SYNCCTRL register with CSCEN=1 and CCCLR=1. After the USART has sent N clock cycles and thus received a character, it clears the CSCEN bit. If more characters need to be received thereafter, software can repeat setting CSCEN and CCCLR.

Aside from such half-duplex operation, the primary use of CSCEN=1 is with SSDIS=0, so that start bits indicate the transmission of each character in each direction.

## 12.6 Functional description

## 12.6.1 RS-485/EIA-485 modes of operation

The RS-485/EIA-485 feature allows the USART to be configured as an addressable slave. The addressable slave is one of multiple slaves controlled by a single master.

The USART master transmitter will identify an address character by setting the parity (9th) bit to '1'. For data characters, the parity bit is set to '0'.

Each USART slave receiver can be assigned a unique address. The slave can be programmed to either manually or automatically reject data following an address which is not theirs.

#### RS-485/EIA-485 Normal Multidrop Mode

Setting the RS485CTRL bit 0 enables this mode. In this mode, an address is detected when a received byte causes the USART to set the parity error and generate an interrupt.

If the receiver is disabled (RS485CTRL bit 1 = '1'), any received data bytes will be ignored and will not be stored in the RXFIFO. When an address byte is detected (parity bit = '1') it will be placed into the RXFIFO and an Rx Data Ready Interrupt will be generated. The processor can then read the address byte and decide whether or not to enable the receiver to accept the following data.

While the receiver is enabled (RS485CTRL bit 1 ='0'), all received bytes will be accepted and stored in the RXFIFO regardless of whether they are data or address. When an address character is received a parity error interrupt will be generated and the processor can decide whether or not to disable the receiver.

#### RS-485/EIA-485 Auto Address Detection (AAD) mode

When both RS485CTRL register bits 0 (9-bit mode enable) and 2 (AAD mode enable) are set, the USART is in auto address detect mode.

In this mode, the receiver will compare any address byte received (parity = '1') to the 8-bit value programmed into the RS485ADRMATCH register.

If the receiver is disabled (RS485CTRL bit 1 = '1'), any received byte will be discarded if it is either a data byte OR an address byte which fails to match the RS485ADRMATCH value.

When a matching address character is detected it will be pushed onto the RXFIFO along with the parity bit, and the receiver will be automatically enabled (RS485CTRL bit 1 will be cleared by hardware). The receiver will also generate an Rx Data Ready Interrupt.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

While the receiver is enabled (RS485CTRL bit 1 = '0'), all bytes received will be accepted and stored in the RXFIFO until an address byte which does not match the RS485ADRMATCH value is received. When this occurs, the receiver will be automatically disabled in hardware (RS485CTRL bit 1 will be set), The received non-matching address character will not be stored in the RXFIFO.

#### RS-485/EIA-485 Auto Direction Control

RS485/EIA-485 mode includes the option of allowing the transmitter to automatically control the state of the DIR pin as a direction control output signal.

Setting RS485CTRL bit 4 = '1' enables this feature.

Keep RS485CTRL bit 3 zero so that direction control, if enabled, will use the RTS pin.

When Auto Direction Control is enabled, the selected pin will be asserted (driven LOW) when the CPU writes data into the TXFIFO. The pin will be de-asserted (driven HIGH) once the last bit of data has been transmitted. See bits 4 and 5 in the RS485CTRL register.

The RS485CTRL bit 4 takes precedence over all other mechanisms controlling the direction control pin with the exception of loopback mode.

#### RS485/EIA-485 driver delay time

The driver delay time is the delay between the last stop bit leaving the TXFIFO and the de-assertion of RTS. This delay time can be programmed in the 8-bit RS485DLY register. The delay time is in periods of the baud clock. Any delay time from 0 to 255 bit times may be used.

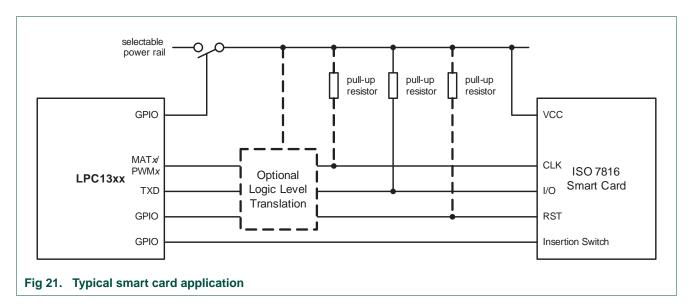

#### RS485/EIA-485 output inversion

The polarity of the direction control signal on the RTS (or DTR) pins can be reversed by programming bit 5 in the RS485CTRL register. When this bit is set, the direction control pin will be driven to logic 1 when the transmitter has data waiting to be sent. The direction control pin will be driven to logic 0 after the last bit of data has been transmitted.

### 12.6.2 Smart card mode

Figure 21 shows a typical asynchronous smart card application.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

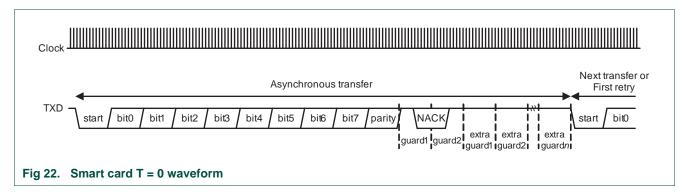

When the SCIEN bit in the SCICTRL register (Table 226) is set as described, the USART provides bidirectional serial data on the open-drain TXD pin. No RXD pin is used when SCIEN is 1. If a clock source is needed as an oscillator source into the Smart Card, a timer match or PWM output can be used in cases when a higher frequency clock is needed that is not synchronous with the data bit rate. The USART SCLK pin will output synchronously with the data and at the data bit rate and may not be adequate for most asynchronous cards. Software must use timers to implement character and block waiting times (no hardware support via trigger signals is provided on the LPC1315/16/17/45/46/47). GPIO pins can be used to control the smart card reset and power pins. Any power supplied to the card must be externally switched as card power supply requirements often exceed source currents possible on the LPC1315/16/17/45/46/47. As the specific application may accommodate any of the available ISO 7816 class A, B, or C power requirements, be aware of the logic level tolerances and requirements when communicating or powering cards that use different power rails than the LPC1315/16/17/45/46/47.

#### 12.6.2.1 Smart card set-up procedure

A T = 0 protocol transfer consists of 8-bits of data, an even parity bit, and two guard bits that allow for the receiver of the particular transfer to flag parity errors through the NACK response (see <a href="Figure 22">Figure 22</a>). Extra guard bits may be added according to card requirements. If no NACK is sent (provided the interface accepts them in SCICTRL), the next byte may be transmitted immediately after the last guard bit. If the NACK is sent, the transmitter will retry sending the byte until successfully received or until the SCICTRL retry limit has been met.

#### Chapter 12: LPC1315/16/17/45/46/47 USART

The smart card must be set up with the following considerations:

- If necessary, program PRESETCTRL (<u>Table 7</u>) so that the USART is not continuously reset.
- Program one IOCON register to enable a USART TXD function.
- If the smart card to be communicated with requires a clock, program one IOCON register for the USART SCLK function. The USART will use it as an output.
- Program UARTCLKDIV (<u>Table 21</u>) for an initial USART frequency of 3.58 MHz.
- Program the OSR (Section 12.5.15) for 372x oversampling.
- If necessary, program the DLM and DLL (<u>Section 12.5.3</u>) to 00 and 01 respectively, to pass the USART clock through without division.
- Program the LCR (Section 12.5.7) for 8-bit characters, parity enabled, even parity.
- Program the GPIO signals associated with the smart card so that (in this order):
  - a. Reset is low.
  - b. VCC is provided to the card (GPIO pins do not have the required 200 mA drive).
  - c. VPP (if provided to the card) is at "idle" state.
- Program SCICTRL (<u>Section 12.5.18</u>) to enable the smart card feature with the desired options.
- Set up one or more timer(s) to provide timing as needed for ISO 7816 startup.
- Program SYSAHBCLKCTRL (Table 19) to enable the USART clock.

Thereafter, software should monitor card insertion, handle activation, wait for answer to reset as described in ISO7816-3.

### 12.7 Architecture

The architecture of the USART is shown below in the block diagram.

The APB interface provides a communications link between the CPU or host and the USART.

The USART receiver block, RX, monitors the serial input line, RXD, for valid input. The USART RX Shift Register (RSR) accepts valid characters via RXD. After a valid character is assembled in the RSR, it is passed to the USART RX Buffer Register FIFO to await access by the CPU or host via the generic host interface.

UM10524 **NXP Semiconductors** 

#### Chapter 12: LPC1315/16/17/45/46/47 USART

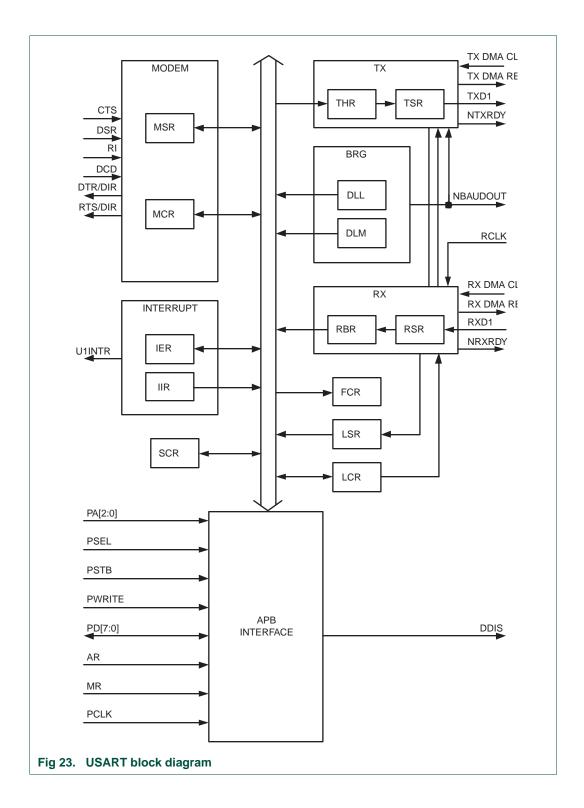

The USART transmitter block, TX, accepts data written by the CPU or host and buffers the data in the USART TX Holding Register FIFO (THR). The USART TX Shift Register (TSR) reads the data stored in the THR and assembles the data to transmit via the serial output pin, TXD1.

The USART Baud Rate Generator block, BRG, generates the timing enables used by the USART TX block. The BRG clock input source is USART\_PCLK. The main clock is divided down per the divisor specified in the DLL and DLM registers. This divided down clock is a 16x oversample clock, NBAUDOUT.

The interrupt interface contains registers IER and IIR. The interrupt interface receives several one clock wide enables from the TX and RX blocks.

Status information from the TX and RX is stored in the LSR. Control information for the TX and RX is stored in the LCR.

# **UM10524**

## Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Rev. 4 — 12 March 2013

**User manual** 

## 13.1 How to read this chapter

Two SSP/SPI interfaces are available on all LPC1315/16/17/45/46/47 parts.

## 13.2 Basic configuration

The SSP0/1 are configured using the following registers:

- 1. Pins: The SSP/SPI pins must be configured in the IOCON register block.
- 2. Power: In the SYSAHBCLKCTRL register, set bit 11 for SSP0 and bit 18 for SSP1 (Table 19).
- 3. Peripheral clock: Enable the SSP0/SSP1 peripheral clocks by writing to the SSP0/1CLKDIV registers (<u>Table 20/Table 22</u>).
- Reset: Before accessing the SSP/SPI block, ensure that the SSP0/1\_RST\_N bits (bit 0 and bit 2) in the PRESETCTRL register (<u>Table 7</u>) are set to 1. This de-asserts the reset signal to the SSP/SPI block.

## 13.3 Features

- Compatible with Motorola SPI, 4-wire TI SSI, and National Semiconductor Microwire buses.
- Synchronous Serial Communication.
- Supports master or slave operation.
- Eight-frame FIFOs for both transmit and receive.
- 4-bit to 16-bit frame.

## 13.4 General description

The SSP/SPI is a Synchronous Serial Port (SSP) controller capable of operation on a SPI, 4-wire SSI, or Microwire bus. It can interact with multiple masters and slaves on the bus. Only a single master and a single slave can communicate on the bus during a given data transfer. Data transfers are in principle full duplex, with frames of 4 bits to 16 bits of data flowing from the master to the slave and from the slave to the master. In practice it is often the case that only one of these data flows carries meaningful data.

## Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

## 13.5 Pin description

Table 231. SSP/SPI pin descriptions

Pin	Туре	Interfa	ice pin function	1	Pin description
name		SPI	SSI	Microwire	·
SCK0/1	I/O	SCK	CLK	SK	Serial Clock. SCK/CLK/SK is a clock signal used to synchronize the transfer of data. It is driven by the master and received by the slave. When SSP/SPI interface is used, the clock is programmable to be active-high or active-low, otherwise it is always active-high. SCK only switches during a data transfer. Any other time, the SSP/SPI interface either holds it in its inactive state or does not drive it (leaves it in high-impedance state).
SSEL0/1	I/O	SSEL	FS	CS	Frame Sync/Slave Select. When the SSP/SPI interface is a bus master, it drives this signal to an active state before the start of serial data and then releases it to an inactive state after the data has been sent. The active state of this signal can be high or low depending upon the selected bus and mode. When the SSP/SPI interface is a bus slave, this signal qualifies the presence of data from the Master according to the protocol in use.
					When there is just one bus master and one bus slave, the Frame Sync or Slave Select signal from the Master can be connected directly to the slave's corresponding input. When there is more than one slave on the bus, further qualification of their Frame Select/Slave Select inputs will typically be necessary to prevent more than one slave from responding to a transfer.
MISO0/1	I/O	MISO	DR(M) DX(S)	SI(M) SO(S)	Master In Slave Out. The MISO signal transfers serial data from the slave to the master. When the SSP/SPI is a slave, serial data is output on this signal. When the SSP/SPI is a master, it clocks in serial data from this signal. When the SSP/SPI is a slave and is not selected by FS/SSEL, it does not drive this signal (leaves it in high-impedance state).
MOSI0/1	I/O	MOSI	DX(M) DR(S)	SO(M) SI(S)	Master Out Slave In. The MOSI signal transfers serial data from the master to the slave. When the SSP/SPI is a master, it outputs serial data on this signal. When the SSP/SPI is a slave, it clocks in serial data from this signal.

# 13.6 Register description

The register addresses of the SPI controllers are shown in <u>Table 232</u>.

The reset value reflects the data stored in used bits only. It does not include the content of reserved bits.

### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

**Remark:** Register names use the SSP prefix to indicate that the SPI controllers have full SSP capabilities.

## 13.6.1 SSP/SPI Control Register 0

This register controls the basic operation of the SSP/SPI controller.

### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Table 234. SSP/SPI Control Register 0 (CR0 - address 0x4004 0000 (SSP0) and 0x4005 8000 (SSP1)) bit description

	100)		escription	
Bit	Symbol	Value	Description	Reset Value
3:0	DSS		Data Size Select. This field controls the number of bits transferred in each frame. Values 0000-0010 are not supported and should not be used.	0000
		0x3	4-bit transfer	
		0x4	5-bit transfer	
		0x5	6-bit transfer	
		0x6	7-bit transfer	
		0x7	8-bit transfer	
		0x8	9-bit transfer	
		0x9	10-bit transfer	
		0xA	11-bit transfer	
		0xB	12-bit transfer	
		0xC	13-bit transfer	
		0xD	14-bit transfer	
		0xE	15-bit transfer	
		0xF	16-bit transfer	
5:4	FRF		Frame Format.	00
		0x0	SPI	
		0x1	TI	
		0x2	Microwire	
		0x3	This combination is not supported and should not be used.	
6	CPOL		Clock Out Polarity. This bit is only used in SPI mode.	0
		0	SPI controller maintains the bus clock low between frames.	
		1	SPI controller maintains the bus clock high between frames.	
7	CPHA		Clock Out Phase. This bit is only used in SPI mode.	0
		0	SPI controller captures serial data on the first clock transition of the frame, that is, the transition <b>away from</b> the inter-frame state of the clock line.	
		1	SPI controller captures serial data on the second clock transition of the frame, that is, the transition <b>back to</b> the inter-frame state of the clock line.	
15:8	SCR		Serial Clock Rate. The number of prescaler output clocks per bit on the bus, minus one. Given that CPSDVSR is the prescale divider, and the APB clock PCLK clocks the prescaler, the bit frequency is PCLK / (CPSDVSR $\times$ [SCR+1]).	0x00
31:16	-	-	Reserved	-
-				

## 13.6.2 SSP/SPI Control Register 1

This register controls certain aspects of the operation of the SSP/SPI controller.

## Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Table 235. SSP/SPI Control Register 1 (CR1 - address 0x4004 0004 (SSP0) and 0x4005 8004 (SSP1)) bit description

	(SOL 1)) bit description			
Bit	Symbol	Value	Description	Reset Value
0	LBM		Loop Back Mode.	0
		0	During normal operation.	
		1	Serial input is taken from the serial output (MOSI or MISO) rather than the serial input pin (MISO or MOSI respectively).	
1	SSE		SPI Enable.	0
		0	The SPI controller is disabled.	
		1	The SPI controller will interact with other devices on the serial bus. Software should write the appropriate control information to the other SSP/SPI registers and interrupt controller registers, before setting this bit.	
2	MS		Master/Slave Mode.This bit can only be written when the SSE bit is 0.	0
		0	The SPI controller acts as a master on the bus, driving the SCLK, MOSI, and SSEL lines and receiving the MISO line.	
		1	The SPI controller acts as a slave on the bus, driving MISO line and receiving SCLK, MOSI, and SSEL lines.	
3	SOD		Slave Output Disable. This bit is relevant only in slave mode (MS = 1). If it is 1, this blocks this SPI controller from driving the transmit data line (MISO).	0
31:4	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.6.3 SSP/SPI Data Register

Software can write data to be transmitted to this register and read data that has been received.

Table 236. SSP/SPI Data Register (DR - address 0x4004 0008 (SSP0) and 0x4005 8008 (SSP1)) bit description

Bit	Symbol	Description	Reset Value
15:0	DATA	Write: software can write data to be sent in a future frame to this register whenever the TNF bit in the Status register is 1, indicating that the Tx FIFO is not full. If the Tx FIFO was previously empty and the SPI controller is not busy on the bus, transmission of the data will begin immediately. Otherwise the data written to this register will be sent as soon as all previous data has been sent (and received). If the data length is less than 16 bit, software must right-justify the data written to this register.	0x0000
		<b>Read:</b> software can read data from this register whenever the RNE bit in the Status register is 1, indicating that the Rx FIFO is not empty. When software reads this register, the SPI controller returns data from the least recent frame in the Rx FIFO. If the data length is less than 16 bit, the data is right-justified in this field with higher order bits filled with 0s.	
31:16	-	Reserved.	-

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

## 13.6.4 SSP/SPI Status Register

This read-only register reflects the current status of the SPI controller.

Table 237. SSP/SPI Status Register (SR - address 0x4004 000C (SSP0) and 0x4005 800C (SSP1)) bit description

Bit	Symbol	Description	Reset Value
0	TFE	Transmit FIFO Empty. This bit is 1 is the Transmit FIFO is empty, 0 if not.	1
1	TNF	Transmit FIFO Not Full. This bit is 0 if the Tx FIFO is full, 1 if not.	1
2	RNE	Receive FIFO Not Empty. This bit is 0 if the Receive FIFO is empty, 1 if not.	0
3	RFF	Receive FIFO Full. This bit is 1 if the Receive FIFO is full, 0 if not.	0
4	BSY	Busy. This bit is 0 if the SPI controller is idle, 1 if it is currently sending/receiving a frame and/or the Tx FIFO is not empty.	0
31:5	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.6.5 SSP/SPI Clock Prescale Register

This register controls the factor by which the Prescaler divides the SPI peripheral clock SPI\_PCLK to yield the prescaler clock that is, in turn, divided by the SCR factor in the SSPCR0 registers, to determine the bit clock.

Table 238. SSP/SPI Clock Prescale Register (CPSR - address 0x4004 0010 (SSP0) and 0x4005 8010 (SSP1)) bit description

Bit	Symbol	Description	Reset Value
7:0	CPSDVSR	This even value between 2 and 254, by which SPI_PCLK is divided to yield the prescaler output clock. Bit 0 always reads as 0.	0
31:8	-	Reserved.	-

**Important:** the SSPnCPSR value must be properly initialized, or the SPI controller will not be able to transmit data correctly.

In Slave mode, the SPI clock rate provided by the master must not exceed 1/12 of the SPI peripheral clock selected in (<u>Table 20/Table 22</u>). The content of the SSPnCPSR register is not relevant.

In master mode, CPSDVSR<sub>min</sub> = 2 or larger (even numbers only).

## 13.6.6 SSP/SPI Interrupt Mask Set/Clear Register

This register controls whether each of the four possible interrupt conditions in the SPI controller are enabled.

## Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Table 239. SSP/SPI Interrupt Mask Set/Clear register (IMSC - address 0x4004 0014 (SSP0) and 0x4005 8014 (SSP1)) bit description

Bit	Symbol	Description	Reset Value
0	RORIM	Software should set this bit to enable interrupt when a Receive Overrun occurs, that is, when the Rx FIFO is full and another frame is completely received. The ARM spec implies that the preceding frame data is overwritten by the new frame data when this occurs.	0
1	RTIM	Software should set this bit to enable interrupt when a Receive Time-out condition occurs. A Receive Time-out occurs when the Rx FIFO is not empty, and no has not been read for a time-out period. The time-out period is the same for master and slave modes and is determined by the SSP bit rate: 32 bits at PCLK / (CPSDVSR × [SCR+1]).	0
2	RXIM	Software should set this bit to enable interrupt when the Rx FIFO is at least half full.	0
3	TXIM	Software should set this bit to enable interrupt when the $TxFIFO$ is at least half empty.	0
31:4	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.6.7 SSP/SPI Raw Interrupt Status Register

This read-only register contains a 1 for each interrupt condition that is asserted, regardless of whether or not the interrupt is enabled in the IMSC registers.

Table 240. SSP/SPI Raw Interrupt Status register (RIS - address 0x4004 0018 (SSP0) and 0x4005 8018 (SSP1)) bit description

	Symbol	Description	Reset value
0	RORRIS	This bit is 1 if another frame was completely received while the RxFIFO was full. The ARM spec implies that the preceding frame data is overwritten by the new frame data when this occurs.	0
1	RTRIS	This bit is 1 if the Rx FIFO is not empty, and has not been read for a time-out period. The time-out period is the same for master and slave modes and is determined by the SSP bit rate: 32 bits at PCLK / (CPSDVSR $\times$ [SCR+1]).	0
2	RXRIS	This bit is 1 if the Rx FIFO is at least half full.	0
3	TXRIS	This bit is 1 if the Tx FIFO is at least half empty.	1
31:4	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.6.8 SSP/SPI Masked Interrupt Status Register

This read-only register contains a 1 for each interrupt condition that is asserted and enabled in the IMSC registers. When an SSP/SPI interrupt occurs, the interrupt service routine should read this register to determine the causes of the interrupt.

## Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Table 241. SSP/SPI Masked Interrupt Status register (MIS - address 0x4004 001C (SSP0) and 0x4005 801C (SSP1)) bit description

Bit	Symbol	Description	Reset value
0	RORMIS	This bit is 1 if another frame was completely received while the RxFIFO was full, and this interrupt is enabled.	0
1	RTMIS	This bit is 1 if the Rx FIFO is not empty, has not been read for a time-out period, and this interrupt is enabled. The time-out period is the same for master and slave modes and is determined by the SSP bit rate: 32 bits at PCLK / (CPSDVSR $\times$ [SCR+1]).	0
2	RXMIS	This bit is 1 if the Rx FIFO is at least half full, and this interrupt is enabled.	0
3	TXMIS	This bit is 1 if the Tx FIFO is at least half empty, and this interrupt is enabled.	0
31:4	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.6.9 SSP/SPI Interrupt Clear Register

Software can write one or more ones to this write-only register, to clear the corresponding interrupt conditions in the SPI controller. Note that the other two interrupt conditions can be cleared by writing or reading the appropriate FIFO or disabled by clearing the corresponding bit in SSPIMSC registers.

Table 242. SSP/SPI interrupt Clear Register (ICR - address 0x4004 0020 (SSP0) and 0x4005 8020 (SSP1)) bit description

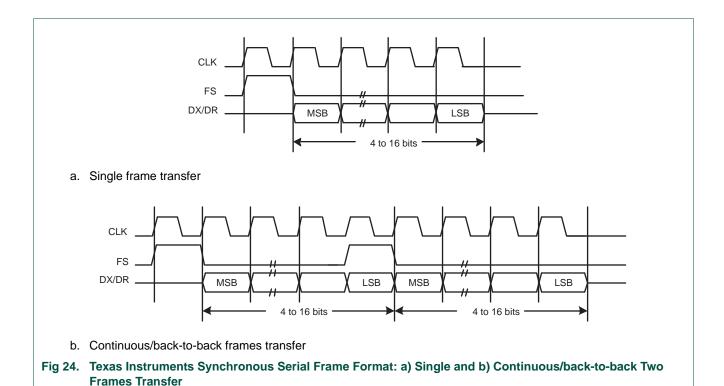

Bit	Symbol	Description	Reset Value
0	RORIC	Writing a 1 to this bit clears the "frame was received when RxFIFO was full" interrupt.	NA
1	RTIC	Writing a 1 to this bit clears the Rx FIFO was not empty and has not been read for a timeout period interrupt. The timeout period is the same for master and slave modes and is determined by the SSP bit rate: 32 bits at PCLK / (CPSDVSR $\times$ [SCR+1]).	NA
31:2	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 13.7 Functional description

## 13.7.1 Texas Instruments synchronous serial frame format

<u>Figure 24</u> shows the 4-wire Texas Instruments synchronous serial frame format supported by the SPI module.

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

For device configured as a master in this mode, CLK and FS are forced LOW, and the transmit data line DX is in 3-state mode whenever the SSP is idle. Once the bottom entry of the transmit FIFO contains data, FS is pulsed HIGH for one CLK period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of CLK, the MSB of the 4-bit to 16-bit data frame is shifted out on the DX pin. Likewise, the MSB of the received data is shifted onto the DR pin by the off-chip serial slave device.

Both the SSP and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each CLK. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of CLK after the LSB has been latched.

#### 13.7.2 SPI frame format

The SPI interface is a four-wire interface where the SSEL signal behaves as a slave select. The main feature of the SPI format is that the inactive state and phase of the SCK signal are programmable through the CPOL and CPHA bits within the SSPCR0 control register.

#### 13.7.2.1 Clock Polarity (CPOL) and Phase (CPHA) control

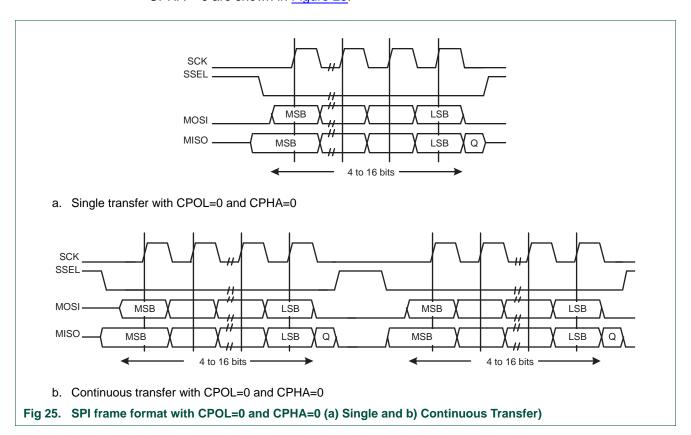

When the CPOL clock polarity control bit is LOW, it produces a steady state low value on the SCK pin. If the CPOL clock polarity control bit is HIGH, a steady state high value is placed on the CLK pin when data is not being transferred.

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

The CPHA control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the CPHA phase control bit is LOW, data is captured on the first clock edge transition. If the CPHA clock phase control bit is HIGH, data is captured on the second clock edge transition.

#### 13.7.2.2 SPI format with CPOL=0,CPHA=0

Single and continuous transmission signal sequences for SPI format with CPOL = 0, CPHA = 0 are shown in Figure 25.

In this configuration, during idle periods:

- The CLK signal is forced LOW.
- SSEL is forced HIGH.
- The transmit MOSI/MISO pad is in high impedance.

If the SSP/SPI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSEL master signal being driven LOW. This causes slave data to be enabled onto the MISO input line of the master. Master's MOSI is enabled.

One half SCK period later, valid master data is transferred to the MOSI pin. Now that both the master and slave data have been set, the SCK master clock pin goes HIGH after one further half SCK period.

The data is captured on the rising and propagated on the falling edges of the SCK signal.

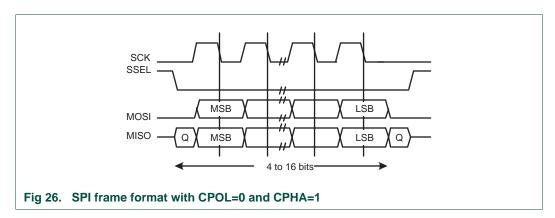

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

In the case of a single word transmission, after all bits of the data word have been transferred, the SSEL line is returned to its idle HIGH state one SCK period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSEL signal must be pulsed HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the CPHA bit is logic zero. Therefore the master device must raise the SSEL pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSEL pin is returned to its idle state one SCK period after the last bit has been captured.

#### 13.7.2.3 SPI format with CPOL=0,CPHA=1

The transfer signal sequence for SPI format with CPOL = 0, CPHA = 1 is shown in Figure 26, which covers both single and continuous transfers.

In this configuration, during idle periods:

- The CLK signal is forced LOW.
- SSEL is forced HIGH.
- The transmit MOSI/MISO pad is in high impedance.

If the SSP/SPI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSEL master signal being driven LOW. Master's MOSI pin is enabled. After a further one half SCK period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the SCK is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SCK signal.

In the case of a single word transfer, after all bits have been transferred, the SSEL line is returned to its idle HIGH state one SCK period after the last bit has been captured.

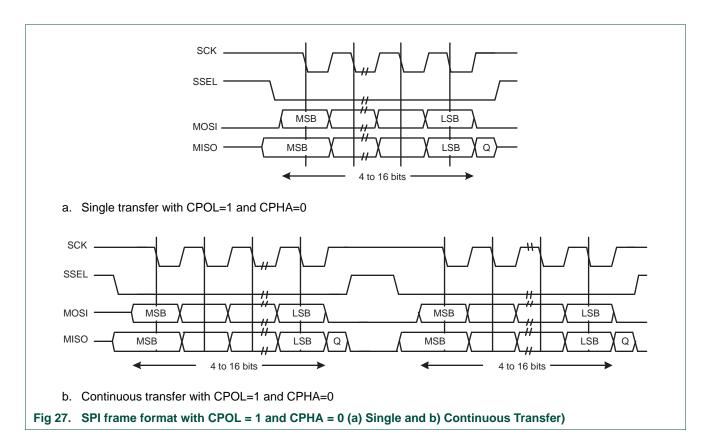

For continuous back-to-back transfers, the SSEL pin is held LOW between successive data words and termination is the same as that of the single word transfer.

#### 13.7.2.4 SPI format with CPOL = 1,CPHA = 0

Single and continuous transmission signal sequences for SPI format with CPOL=1, CPHA=0 are shown in Figure 27.

UM10524

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

In this configuration, during idle periods:

- The CLK signal is forced HIGH.
- SSEL is forced HIGH.
- The transmit MOSI/MISO pad is in high impedance.

If the SSP/SPI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSEL master signal being driven LOW, which causes slave data to be immediately transferred onto the MISO line of the master. Master's MOSI pin is enabled.

One half period later, valid master data is transferred to the MOSI line. Now that both the master and slave data have been set, the SCK master clock pin becomes LOW after one further half SCK period. This means that data is captured on the falling edges and be propagated on the rising edges of the SCK signal.

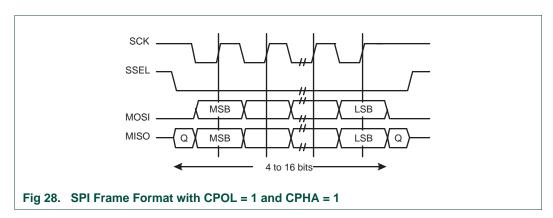

In the case of a single word transmission, after all bits of the data word are transferred, the SSEL line is returned to its idle HIGH state one SCK period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSEL signal must be pulsed HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the CPHA bit is logic zero. Therefore the master device must raise the SSEL pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSEL pin is returned to its idle state one SCK period after the last bit has been captured.

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

#### 13.7.2.5 SPI format with CPOL = 1, CPHA = 1

The transfer signal sequence for SPI format with CPOL = 1, CPHA = 1 is shown in Figure 28, which covers both single and continuous transfers.

In this configuration, during idle periods:

- The CLK signal is forced HIGH.
- SSEL is forced HIGH.
- The transmit MOSI/MISO pad is in high impedance.

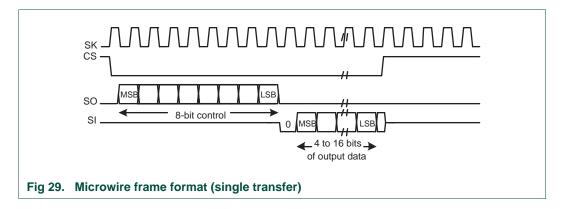

If the SSP/SPI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSEL master signal being driven LOW. Master's MOSI is enabled. After a further one half SCK period, both master and slave data are enabled onto their respective transmission lines. At the same time, the SCK is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SCK signal.

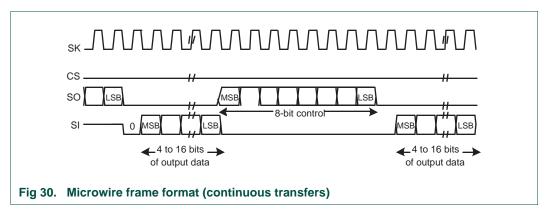

After all bits have been transferred, in the case of a single word transmission, the SSEL line is returned to its idle HIGH state one SCK period after the last bit has been captured. For continuous back-to-back transmissions, the SSEL pins remains in its active LOW state, until the final bit of the last word has been captured, and then returns to its idle state as described above. In general, for continuous back-to-back transfers the SSEL pin is held LOW between successive data words and termination is the same as that of the single word transfer.

#### 13.7.3 Semiconductor Microwire frame format

<u>Figure 29</u> shows the Microwire frame format for a single frame. <u>Figure 30</u> shows the same format when back-to-back frames are transmitted.

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

Microwire format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSP/SPI to the off-chip slave device. During this transmission, no incoming data is received by the SSP/SPI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bit in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- The SK signal is forced LOW.
- CS is forced HIGH.
- The transmit data line SO is arbitrarily forced LOW.

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of CS causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SO pin. CS remains LOW for the duration of the frame transmission. The SI pin remains tri-stated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SK. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSP/SPI. Each bit is driven onto SI line on the falling edge of SK. The SSP/SPI in

#### Chapter 13: LPC1315/16/17/45/46/47 SSP/SPI

turn latches each bit on the rising edge of SK. At the end of the frame, for single transfers, the CS signal is pulled HIGH one clock period after the last bit has been latched in the receive serial shifter, that causes the data to be transferred to the receive FIFO.

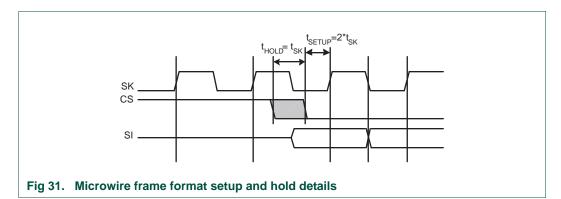

**Note:** The off-chip slave device can tri-state the receive line either on the falling edge of SK after the LSB has been latched by the receive shiftier, or when the CS pin goes HIGH.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the CS line is continuously asserted (held LOW) and transmission of data occurs back to back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge SK, after the LSB of the frame has been latched into the SSP/SPI.

# 13.7.3.1 Setup and hold time requirements on CS with respect to SK in Microwire mode

In the Microwire mode, the SSP/SPI slave samples the first bit of receive data on the rising edge of SK after CS has gone LOW. Masters that drive a free-running SK must ensure that the CS signal has sufficient setup and hold margins with respect to the rising edge of SK.

<u>Figure 31</u> illustrates these setup and hold time requirements. With respect to the SK rising edge on which the first bit of receive data is to be sampled by the SSP/SPI slave, CS must have a setup of at least two times the period of SK on which the SSP/SPI operates. With respect to the SK rising edge previous to this edge, CS must have a hold of at least one SK period.

## Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Rev. 4 — 12 March 2013

**User manual** 

## 14.1 How to read this chapter

The I<sup>2</sup>C-bus block is identical for all LPC1315/16/17/45/46/47 parts.

## 14.2 Basic configuration

The I<sup>2</sup>C-bus interface is configured using the following registers:

- 1. Pins: The I2C pin functions and the I2C mode are configured in the IOCON register block (Table 60 and Table 61).
- 2. Power and peripheral clock: In the SYSAHBCLKCTRL register, set bit 5 (Table 19).
- Reset: Before accessing the I2C block, ensure that the I2C\_RST\_N bit (bit 1) in the PRESETCTRL register (<u>Table 7</u>) is set to 1. This de-asserts the reset signal to the I2C block.

#### 14.3 Features

- The I<sup>2</sup>C-bus contains a standard I<sup>2</sup>C-compliant bus interface with two pins.
- The I<sup>2</sup>C- bus interfaces may be configured as Master, Slave, or Master/Slave.
- Supports Fast-mode Plus.
- Arbitration is handled between simultaneously transmitting masters without corruption of serial data on the bus.
- Programmable clock allows adjustment of I<sup>2</sup>C transfer rates.
- Data transfer is bidirectional between masters and slaves.
- Serial clock synchronization allows devices with different bit rates to communicate via one serial bus.
- Serial clock synchronization is used as a handshake mechanism to suspend and resume serial transfer.
- Optional recognition of up to four distinct slave addresses.
- Monitor mode allows observing all I<sup>2</sup>C-bus traffic, regardless of slave address.
- I<sup>2</sup>C-bus can be used for test and diagnostic purposes.

## 14.4 Applications

Interfaces to external I<sup>2</sup>C standard parts, such as serial RAMs, LCDs, tone generators, other microcontrollers, etc.

## 14.5 General description

A typical I<sup>2</sup>C-bus configuration is shown in <u>Figure 32</u>. Depending on the state of the direction bit (R/W), two types of data transfers are possible on the I<sup>2</sup>C-bus:

UM10524 **NXP Semiconductors** 

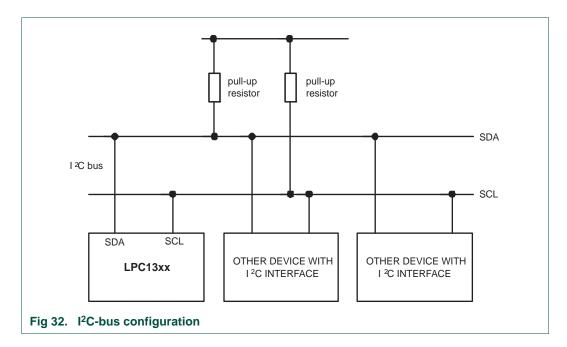

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Data transfer from a master transmitter to a slave receiver. The first byte transmitted by the master is the slave address. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte.

 Data transfer from a slave transmitter to a master receiver. The first byte (the slave address) is transmitted by the master. The slave then returns an acknowledge bit. Next follows the data bytes transmitted by the slave to the master. The master returns an acknowledge bit after all received bytes other than the last byte. At the end of the last received byte, a "not acknowledge" is returned. The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a Repeated START condition. Since a Repeated START condition is also the beginning of the next serial transfer, the I<sup>2</sup>C bus will not be released.

The I<sup>2</sup>C interface is byte oriented and has four operating modes: master transmitter mode, master receiver mode, slave transmitter mode and slave receiver mode.

The I<sup>2</sup>C interface complies with the entire I<sup>2</sup>C specification, supporting the ability to turn power off to the ARM Cortex-M3 without interfering with other devices on the same I<sup>2</sup>C-bus.

#### 14.5.1 I<sup>2</sup>C Fast-mode Plus

Fast-Mode Plus supports a 1 Mbit/sec transfer rate to communicate with the I<sup>2</sup>C-bus products which NXP Semiconductors is now providing.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

## 14.6 Pin description

Table 243. I<sup>2</sup>C-bus pin description

Pin	Туре	Description
SDA	Input/Output	I <sup>2</sup> C Serial Data
SCL	Input/Output	I <sup>2</sup> C Serial Clock

The I<sup>2</sup>C-bus pins must be configured through the IOCON\_PIO0\_4 (<u>Table 60</u>) and IOCON\_PIO0\_5 (<u>Table 61</u>) registers for Standard/ Fast-mode or Fast-mode Plus. In Fast-mode Plus, rates above 400 kHz and up to 1 MHz may be selected. The I<sup>2</sup>C-bus pins are open-drain outputs and fully compatible with the I<sup>2</sup>C-bus specification.

## 14.7 Register description

Table 244. Register overview: I<sup>2</sup>C (base address 0x4000 0000)

Name	Access	Address offset	Description	Reset value[1]	Reference
CONSET	R/W	0x000	<b>I2C Control Set Register.</b> When a one is written to a bit of this register, the corresponding bit in the I <sup>2</sup> C control register is set. Writing a zero has no effect on the corresponding bit in the I <sup>2</sup> C control register.	0x00	Table 245
STAT	RO	0x004	<b>I2C Status Register.</b> During I <sup>2</sup> C operation, this register provides detailed status codes that allow software to determine the next action needed.	0xF8	Table 246
DAT	R/W	0x008	<b>I2C Data Register.</b> During master or slave transmit mode, data to be transmitted is written to this register. During master or slave receive mode, data that has been received may be read from this register.	0x00	Table 247
ADR0	R/W	0x00C	<b>I2C Slave Address Register 0.</b> Contains the 7-bit slave address for operation of the I <sup>2</sup> C interface in slave mode, and is not used in master mode. The least significant bit determines whether a slave responds to the General Call address.	0x00	Table 248
SCLH	R/W	0x010	<b>SCH Duty Cycle Register High Half Word.</b> Determines the high time of the I <sup>2</sup> C clock.	0x04	<u>Table 249</u>
SCLL	R/W	0x014	SCL Duty Cycle Register Low Half Word. Determines the low time of the I <sup>2</sup> C clock. I2nSCLL and I2nSCLH together determine the clock frequency generated by an I <sup>2</sup> C master and certain times used in slave mode.	0x04	Table 250
CONCLR	WO	0x018	<b>I2C Control Clear Register.</b> When a one is written to a bit of this register, the corresponding bit in the I <sup>2</sup> C control register is cleared. Writing a zero has no effect on the corresponding bit in the I <sup>2</sup> C control register.	NA	Table 252

<sup>[1]</sup> Reset value reflects the data stored in used bits only. It does not include reserved bits content.

## 14.7.1 I<sup>2</sup>C Control Set register (CONSET)

The CONSET registers control setting of bits in the CON register that controls operation of the  $I^2C$  interface. Writing a one to a bit of this register causes the corresponding bit in the  $I^2C$  control register to be set. Writing a zero has no effect.

Table 245. I<sup>2</sup>C Control Set register (CONSET - address 0x4000 0000) bit description

Bit	Symbol	Description	Reset value
1:0	-	Reserved. User software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
2	AA	Assert acknowledge flag.	
3	SI	I <sup>2</sup> C interrupt flag.	0
4	STO	STOP flag.	0

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 245. I<sup>2</sup>C Control Set register (CONSET - address 0x4000 0000) bit description

Bit	Symbol	Description	Reset value
5	STA	START flag.	0
6	I2EN	I <sup>2</sup> C interface enable.	0
31:7	-	Reserved. The value read from a reserved bit is not defined.	-

**I2EN** I<sup>2</sup>C Interface Enable. When I2EN is 1, the I<sup>2</sup>C interface is enabled. I2EN can be cleared by writing 1 to the I2ENC bit in the CONCLR register. When I2EN is 0, the I<sup>2</sup>C interface is disabled.

When I2EN is "0", the SDA and SCL input signals are ignored, the I<sup>2</sup>C block is in the "not addressed" slave state, and the STO bit is forced to "0".

I2EN should not be used to temporarily release the I<sup>2</sup>C-bus since, when I2EN is reset, the I<sup>2</sup>C-bus status is lost. The AA flag should be used instead.

**STA** is the START flag. Setting this bit causes the I<sup>2</sup>C interface to enter master mode and transmit a START condition or transmit a Repeated START condition if it is already in master mode.

When STA is 1 and the I<sup>2</sup>C interface is not already in master mode, it enters master mode, checks the bus and generates a START condition if the bus is free. If the bus is not free, it waits for a STOP condition (which will free the bus) and generates a START condition after a delay of a half clock period of the internal clock generator. If the I<sup>2</sup>C interface is already in master mode and data has been transmitted or received, it transmits a Repeated START condition. STA may be set at any time, including when the I<sup>2</sup>C interface is in an addressed slave mode.

STA can be cleared by writing 1 to the STAC bit in the CONCLR register. When STA is 0, no START condition or Repeated START condition will be generated.

If STA and STO are both set, then a STOP condition is transmitted on the  $I^2C$ -bus if it the interface is in master mode, and transmits a START condition thereafter. If the  $I^2C$  interface is in slave mode, an internal STOP condition is generated, but is not transmitted on the bus.

**STO** is the STOP flag. Setting this bit causes the I<sup>2</sup>C interface to transmit a STOP condition in master mode, or recover from an error condition in slave mode. When STO is 1 in master mode, a STOP condition is transmitted on the I<sup>2</sup>C-bus. When the bus detects the STOP condition, STO is cleared automatically.

In slave mode, setting this bit can recover from an error condition. In this case, no STOP condition is transmitted to the bus. The hardware behaves as if a STOP condition has been received and it switches to "not addressed" slave receiver mode. The STO flag is cleared by hardware automatically.

**SI** is the I<sup>2</sup>C Interrupt Flag. This bit is set when the I<sup>2</sup>C state changes. However, entering state F8 does not set SI since there is nothing for an interrupt service routine to do in that case.

While SI is set, the low period of the serial clock on the SCL line is stretched, and the serial transfer is suspended. When SCL is HIGH, it is unaffected by the state of the SI flag. SI must be reset by software, by writing a 1 to the SIC bit in the CONCLR register.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

**AA** is the Assert Acknowledge Flag. When set to 1, an acknowledge (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line on the following situations:

- 1. The address in the Slave Address Register has been received.
- 2. The General Call address has been received while the General Call bit (GC) in the ADR register is set.
- 3. A data byte has been received while the I<sup>2</sup>C is in the master receiver mode.
- 4. A data byte has been received while the I<sup>2</sup>C is in the addressed slave receiver mode

The AA bit can be cleared by writing 1 to the AAC bit in the CONCLR register. When AA is 0, a not acknowledge (HIGH level to SDA) will be returned during the acknowledge clock pulse on the SCL line on the following situations:

- 1. A data byte has been received while the I<sup>2</sup>C is in the master receiver mode.
- 2. A data byte has been received while the I<sup>2</sup>C is in the addressed slave receiver mode.

### 14.7.2 I<sup>2</sup>C Status register (STAT)

Each I<sup>2</sup>C Status register reflects the condition of the corresponding I<sup>2</sup>C interface. The I<sup>2</sup>C Status register is Read-Only.

Table 246. I<sup>2</sup>C Status register (STAT - 0x4000 0004) bit description

Bit	Symbol	Description	Reset value
2:0	-	These bits are unused and are always 0.	0
7:3	Status	These bits give the actual status information about the I <sup>2</sup> C interface.	0x1F
31:8	-	Reserved. The value read from a reserved bit is not defined.	-

The three least significant bits are always 0. Taken as a byte, the status register contents represent a status code. There are 26 possible status codes. When the status code is 0xF8, there is no relevant information available and the SI bit is not set. All other 25 status codes correspond to defined I<sup>2</sup>C states. When any of these states entered, the SI bit will be set. For a complete list of status codes, refer to tables from Table 261 to Table 266.

## 14.7.3 I<sup>2</sup>C Data register (DAT)

This register contains the data to be transmitted or the data just received. The CPU can read and write to this register only while it is not in the process of shifting a byte, when the SI bit is set. Data in DAT register remains stable as long as the SI bit is set. Data in DAT register is always shifted from right to left: the first bit to be transmitted is the MSB (bit 7), and after a byte has been received, the first bit of received data is located at the MSB of the DAT register.

Table 247. I<sup>2</sup>C Data register (DAT - 0x4000 0008) bit description

Bit	Symbol	Description	Reset value
7:0	Data	This register holds data values that have been received or are to be transmitted.	0
31:8	-	Reserved. The value read from a reserved bit is not defined.	-

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

### 14.7.4 I<sup>2</sup>C Slave Address register 0 (ADR0)

This register is readable and writable and are only used when an I<sup>2</sup>C interface is set to slave mode. In master mode, this register has no effect. The LSB of the ADR register is the General Call bit. When this bit is set, the General Call address (0x00) is recognized.

If this register contains 0x00, the I<sup>2</sup>C will not acknowledge any address on the bus. All four registers (ADR0 to ADR3) will be cleared to this disabled state on reset. See also Table 254.

Table 248. I<sup>2</sup>C Slave Address register 0 (ADR0- 0x4000 000C) bit description

Bit	Symbol	Description	Reset value
0	GC	General Call enable bit.	0
7:1	Address	The I <sup>2</sup> C device address for slave mode.	0x00
31:8	-	Reserved. The value read from a reserved bit is not defined.	-

### 14.7.5 I<sup>2</sup>C SCL HIGH and LOW duty cycle registers (SCLH and SCLL)

Table 249. I<sup>2</sup>C SCL HIGH Duty Cycle register (SCLH - address 0x4000 0010) bit description

Bit	Symbol	Description	Reset value
15:0	SCLH	Count for SCL HIGH time period selection.	0x0004
31:16	-	Reserved. The value read from a reserved bit is not defined.	-

Table 250. I<sup>2</sup>C SCL Low duty cycle register (SCLL - 0x4000 0014) bit description

Bit	Symbol	Description	Reset value
15:0	SCLL	Count for SCL low time period selection.	0x0004
31:16	-	Reserved. The value read from a reserved bit is not defined.	-

#### 14.7.5.1 Selecting the appropriate I<sup>2</sup>C data rate and duty cycle

Software must set values for the registers SCLH and SCLL to select the appropriate data rate and duty cycle. SCLH defines the number of I2C\_PCLK cycles for the SCL HIGH time, SCLL defines the number of I2C\_PCLK cycles for the SCL low time. The frequency is determined by the following formula (I2C\_PCLK is the frequency of the peripheral I2C clock):

(4)

$$I^2C_{bitfrequency} = \frac{I2CPCLK}{SCLH + SCLL}$$

The values for SCLL and SCLH must ensure that the data rate is in the appropriate I<sup>2</sup>C data rate range. Each register value must be greater than or equal to 4. <u>Table 251</u> gives some examples of I<sup>2</sup>C-bus rates based on I2C\_PCLK frequency and SCLL and SCLH values.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 251. SCLL + SCLH values for selected I<sup>2</sup>C clock values

I <sup>2</sup> C mode	I <sup>2</sup> C bit				I2C_	_PCLK	(MHz)			
	frequency	6	8	10	12	16	20	30	40	50
		SCLH + SCLL								
Standard mode	100 kHz	60	80	100	120	160	200	300	400	500
Fast-mode	400 kHz	15	20	25	30	40	50	75	100	125
Fast-mode Plus	1 MHz	-	8	10	12	16	20	30	40	50

SCLL and SCLH values should not necessarily be the same. Software can set different duty cycles on SCL by setting these two registers. For example, the I<sup>2</sup>C-bus specification defines the SCL low time and high time at different values for a Fast-mode and Fast-mode Plus I<sup>2</sup>C.

## 14.7.6 I<sup>2</sup>C Control Clear register (CONCLR)

The CONCLR register control clearing of bits in the CON register that controls operation of the I<sup>2</sup>C interface. Writing a one to a bit of this register causes the corresponding bit in the I<sup>2</sup>C control register to be cleared. Writing a zero has no effect.

Table 252. I<sup>2</sup>C Control Clear register (CONCLR - 0x4000 0018) bit description

Bit	Symbol	Description	Reset value
1:0	-	Reserved. User software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
2	AAC	Assert acknowledge Clear bit.	
3	SIC	I <sup>2</sup> C interrupt Clear bit.	0
4	-	Reserved. User software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
5	STAC	START flag Clear bit.	0
6	I2ENC	I <sup>2</sup> C interface Disable bit.	0
7	-	Reserved. User software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
31:8	-	Reserved. The value read from a reserved bit is not defined.	-

**AAC** is the Assert Acknowledge Clear bit. Writing a 1 to this bit clears the AA bit in the CONSET register. Writing 0 has no effect.

**SIC** is the I<sup>2</sup>C Interrupt Clear bit. Writing a 1 to this bit clears the SI bit in the CONSET register. Writing 0 has no effect.

**STAC** is the START flag Clear bit. Writing a 1 to this bit clears the STA bit in the CONSET register. Writing 0 has no effect.

**I2ENC** is the I<sup>2</sup>C Interface Disable bit. Writing a 1 to this bit clears the I2EN bit in the CONSET register. Writing 0 has no effect.

## 14.7.7 I<sup>2</sup>C Monitor mode control register (MMCTRL)

This register controls the Monitor mode which allows the I<sup>2</sup>C module to monitor traffic on the I<sup>2</sup>C bus without actually participating in traffic or interfering with the I<sup>2</sup>C bus.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 253. I<sup>2</sup>C Monitor mode control register (MMCTRL - 0x4000 001C) bit description

Bit	Symbol	Value	Description	Reset value		
0	MM_ENA		Monitor mode enable.	0		
		0	Monitor mode disabled.			
		1	The I <sup>2</sup> C module will enter monitor mode. In this mode the SDA output will be forced high. This will prevent the I <sup>2</sup> C module from outputting data of any kind (including ACK) onto the I <sup>2</sup> C data bus.			
			Depending on the state of the ENA_SCL bit, the output may be also forced high, preventing the module from having control over the I <sup>2</sup> C clock line.			
1	1 ENA_SCL		SCL output enable.	0		
				0	When this bit is cleared to '0', the SCL output will be forced high when the module is in monitor mode. As described above, this will prevent the module from having any control over the I <sup>2</sup> C clock line.	
		1	When this bit is set, the I <sup>2</sup> C module may exercise the same control over the clock line that it would in normal operation. This means that, acting as a slave peripheral, the I <sup>2</sup> C module can "stretch" the clock line (hold it low) until it has had time to respond to an I <sup>2</sup> C interrupt.[1]			
2	MATCH_ALL		Select interrupt register match.	0		
			When this bit is cleared, an interrupt will only be generated when a match occurs to one of the (up-to) four address registers described above. That is, the module will respond as a normal slave as far as address-recognition is concerned.			
		1	When this bit is set to '1' and the I <sup>2</sup> C is in monitor mode, an interrupt will be generated on ANY address received. This will enable the part to monitor all traffic on the bus.			
31:3	-	-	Reserved. The value read from reserved bits is not defined.			

<sup>[1]</sup> When the ENA\_SCL bit is cleared and the I<sup>2</sup>C no longer has the ability to stall the bus, interrupt response time becomes important. To give the part more time to respond to an I<sup>2</sup>C interrupt under these conditions, a DATA\_BUFFER register is used (Section 14.7.9) to hold received data for a full 9-bit word transmission time.

**Remark:** The ENA\_SCL and MATCH\_ALL bits have no effect if the MM\_ENA is '0' (i.e. if the module is NOT in monitor mode).

#### 14.7.7.1 Interrupt in Monitor mode

All interrupts will occur as normal when the module is in monitor mode. This means that the first interrupt will occur when an address-match is detected (any address received if the MATCH\_ALL bit is set, otherwise an address matching one of the four address registers).

Subsequent to an address-match detection, interrupts will be generated after each data byte is received for a slave-write transfer, or after each byte that the module "thinks" it has transmitted for a slave-read transfer. In this second case, the data register will actually contain data transmitted by some other slave on the bus which was actually addressed by the master.

265 of 416

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Following all of these interrupts, the processor may read the data register to see what was actually transmitted on the bus.

#### 14.7.7.2 Loss of arbitration in Monitor mode

In monitor mode, the I<sup>2</sup>C module will not be able to respond to a request for information by the bus master or issue an ACK). Some other slave on the bus will respond instead. This will most probably result in a lost-arbitration state as far as our module is concerned.

Software should be aware of the fact that the module is in monitor mode and should not respond to any loss of arbitration state that is detected. In addition, hardware may be designed into the module to block some/all loss of arbitration states from occurring if those state would either prevent a desired interrupt from occurring or cause an unwanted interrupt to occur. Whether any such hardware will be added is still to be determined.

## 14.7.8 I<sup>2</sup>C Slave Address registers (ADR[1, 2, 3])

These registers are readable and writable and are only used when an I<sup>2</sup>C interface is set to slave mode. In master mode, this register has no effect. The LSB of the ADR register is the General Call bit. When this bit is set, the General Call address (0x00) is recognized.

If these registers contain 0x00, the I<sup>2</sup>C will not acknowledge any address on the bus. All four registers will be cleared to this disabled state on reset (also see <u>Table 248</u>).

Table 254. I<sup>2</sup>C Slave Address registers (ADR[1, 2, 3]- 0x4000 00[20, 24, 28]) bit description

Bit	Symbol	Description	Reset value
0	GC	General Call enable bit.	0
7:1	Address	The I <sup>2</sup> C device address for slave mode.	0x00
31:8	-	Reserved. The value read from a reserved bit is not defined.	0

## 14.7.9 I<sup>2</sup>C Data buffer register (DATA\_BUFFER)

In monitor mode, the I<sup>2</sup>C module may lose the ability to stretch the clock (stall the bus) if the ENA\_SCL bit is not set. This means that the processor will have a limited amount of time to read the contents of the data received on the bus. If the processor reads the DAT shift register, as it ordinarily would, it could have only one bit-time to respond to the interrupt before the received data is overwritten by new data.

To give the processor more time to respond, a new 8-bit, read-only DATA\_BUFFER register will be added. The contents of the 8 MSBs of the DAT shift register will be transferred to the DATA\_BUFFER automatically after every nine bits (8 bits of data plus ACK or NACK) has been received on the bus. This means that the processor will have nine bit transmission times to respond to the interrupt and read the data before it is overwritten.

The processor will still have the ability to read the DAT register directly, as usual, and the behavior of DAT will not be altered in any way.

Although the DATA\_BUFFER register is primarily intended for use in monitor mode with the ENA\_SCL bit = '0', it will be available for reading at any time under any mode of operation.

266 of 416

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 255. I<sup>2</sup>C Data buffer register (DATA\_BUFFER - 0x4000 002C) bit description

Bit	Symbol	Description	Reset value
7:0	Data	This register holds contents of the 8 MSBs of the DAT shift register.	0
31:8	-	Reserved. The value read from a reserved bit is not defined.	0

### 14.7.10 I<sup>2</sup>C Mask registers (MASK[0, 1, 2, 3])

The four mask registers each contain seven active bits (7:1). Any bit in these registers which is set to '1' will cause an automatic compare on the corresponding bit of the received address when it is compared to the ADRn register associated with that mask register. In other words, bits in an ADRn register which are masked are not taken into account in determining an address match.

On reset, all mask register bits are cleared to '0'.

The mask register has no effect on comparison to the General Call address ("0000000").

Bits(31:8) and bit(0) of the mask registers are unused and should not be written to. These bits will always read back as zeros.

When an address-match interrupt occurs, the processor will have to read the data register (DAT) to determine what the received address was that actually caused the match.

Table 256. I<sup>2</sup>C Mask registers (MASK[0, 1, 2, 3] - 0x4000 00[30, 34, 38, 3C]) bit description

Bit	Symbol	Description	Reset value
0	-	Reserved. User software should not write ones to reserved bits. This bit reads always back as 0.	0
7:1	MASK	Mask bits.	0x00
31:8	-	Reserved. The value read from reserved bits is undefined.	0

## 14.8 I<sup>2</sup>C operating modes

In a given application, the I<sup>2</sup>C block may operate as a master, a slave, or both. In the slave mode, the I<sup>2</sup>C hardware looks for any one of its four slave addresses and the General Call address. If one of these addresses is detected, an interrupt is requested. If the processor wishes to become the bus master, the hardware waits until the bus is free before the master mode is entered so that a possible slave operation is not interrupted. If bus arbitration is lost in the master mode, the I<sup>2</sup>C block switches to the slave mode immediately and can detect its own slave address in the same serial transfer.

## 14.8.1 Master Transmitter mode

In this mode data is transmitted from master to slave. Before the master transmitter mode can be entered, the CONSET register must be initialized as shown in <u>Table 257</u>. I2EN must be set to 1 to enable the I<sup>2</sup>C function. If the AA bit is 0, the I<sup>2</sup>C interface will not acknowledge any address when another device is master of the bus, so it can not enter slave mode. The STA, STO and SI bits must be 0. The SI Bit is cleared by writing 1 to the SIC bit in the CONCLR register. THe STA bit should be cleared after writing the slave address.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

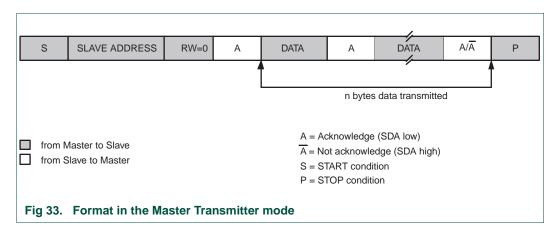

Table 257. CONSET used to configure Master mode

Bit	7	6	5	4	3	2	1	0
Symbol	-	I2EN	STA	STO	SI	AA	-	-
Value	-	1	0	0	0	0	-	-

The first byte transmitted contains the slave address of the receiving device (7 bits) and the data direction bit. In this mode the data direction bit (R/W) should be 0 which means Write. The first byte transmitted contains the slave address and Write bit. Data is transmitted 8 bits at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

The I<sup>2</sup>C interface will enter master transmitter mode when software sets the STA bit. The I<sup>2</sup>C logic will send the START condition as soon as the bus is free. After the START condition is transmitted, the SI bit is set, and the status code in the STAT register is 0x08. This status code is used to vector to a state service routine which will load the slave address and Write bit to the DAT register, and then clear the SI bit. SI is cleared by writing a 1 to the SIC bit in the CONCLR register.

When the slave address and R/W bit have been transmitted and an acknowledgment bit has been received, the SI bit is set again, and the possible status codes now are 0x18, 0x20, or 0x38 for the master mode, or 0x68, 0x78, or 0xB0 if the slave mode was enabled (by setting AA to 1). The appropriate actions to be taken for each of these status codes are shown in Table 261 to Table 266.

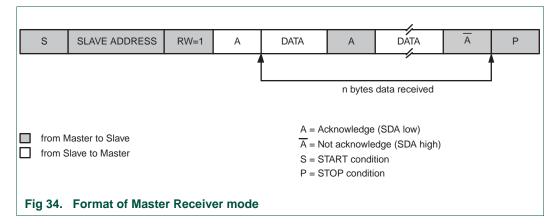

### 14.8.2 Master Receiver mode

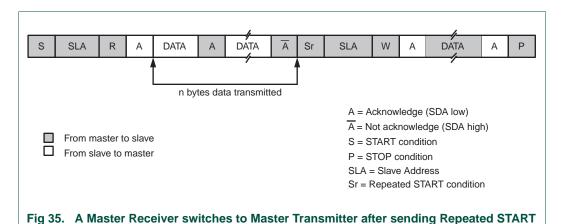

In the master receiver mode, data is received from a slave transmitter. The transfer is initiated in the same way as in the master transmitter mode. When the START condition has been transmitted, the interrupt service routine must load the slave address and the data direction bit to the I<sup>2</sup>C Data register (DAT), and then clear the SI bit. In this case, the data direction bit (R/W) should be 1 to indicate a read.

When the slave address and data direction bit have been transmitted and an acknowledge bit has been received, the SI bit is set, and the Status Register will show the status code. For master mode, the possible status codes are 0x40, 0x48, or 0x38. For slave mode, the possible status codes are 0x68, 0x78, or 0xB0. For details, refer to Table 262.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

After a Repeated START condition, I<sup>2</sup>C may switch to the master transmitter mode.

#### 14.8.3 Slave Receiver mode

In the slave receiver mode, data bytes are received from a master transmitter. To initialize the slave receiver mode, write any of the Slave Address registers (ADR0-3) and write the I<sup>2</sup>C Control Set register (CONSET) as shown in Table 258.

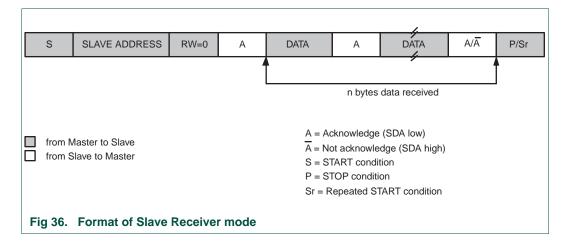

Table 258. CONSET used to configure Slave mode

Bit	7	6	5	4	3	2	1	0
Symbol	-	I2EN	STA	STO	SI	AA	-	-
Value	-	1	0	0	0	1	-	-

I2EN must be set to 1 to enable the I<sup>2</sup>C function. AA bit must be set to 1 to acknowledge its own slave address or the General Call address. The STA, STO and SI bits are set to 0.

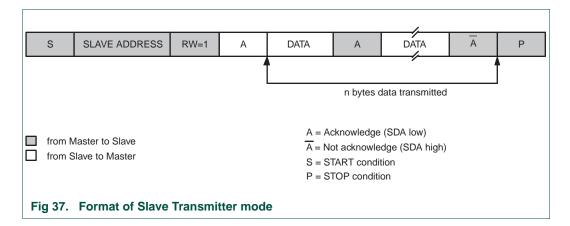

After ADR and CONSET are initialized, the I<sup>2</sup>C interface waits until it is addressed by its own address or general address followed by the data direction bit. If the direction bit is 0 (W), it enters slave receiver mode. If the direction bit is 1 (R), it enters slave transmitter mode. After the address and direction bit have been received, the SI bit is set and a valid status code can be read from the Status register (STAT). Refer to <a href="Table 265">Table 265</a> for the status codes and actions.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

#### 14.8.4 Slave Transmitter mode

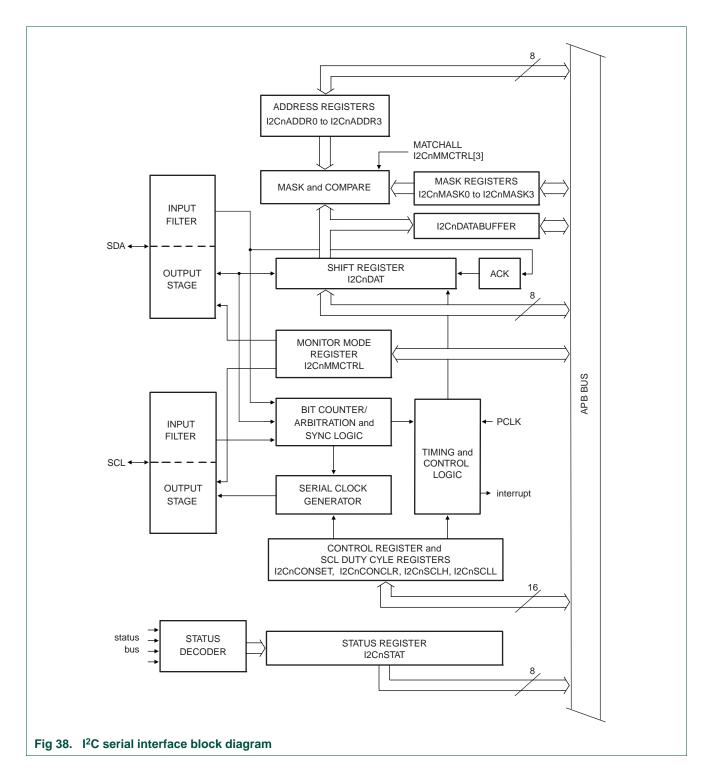

The first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit will be 1, indicating a read operation. Serial data is transmitted via SDA while the serial clock is input through SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer. In a given application, I<sup>2</sup>C may operate as a master and as a slave. In the slave mode, the I<sup>2</sup>C hardware looks for its own slave address and the General Call address. If one of these addresses is detected, an interrupt is requested. When the microcontrollers wishes to become the bus master, the hardware waits until the bus is free before the master mode is entered so that a possible slave action is not interrupted. If bus arbitration is lost in the master mode, the I<sup>2</sup>C interface switches to the slave mode immediately and can detect its own slave address in the same serial transfer.

## 14.9 I<sup>2</sup>C implementation and operation

<u>Figure 38</u> shows how the on-chip I<sup>2</sup>C-bus interface is implemented, and the following text describes the individual blocks.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

## 14.9.1 Input filters and output stages

Input signals are synchronized with the internal clock, and spikes shorter than three clocks are filtered out.

The output for I<sup>2</sup>C is a special pad designed to conform to the I<sup>2</sup>C specification.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

### 14.9.2 Address Registers, ADR0 to ADR3

These registers may be loaded with the 7-bit slave address (7 most significant bits) to which the I<sup>2</sup>C block will respond when programmed as a slave transmitter or receiver. The LSB (GC) is used to enable General Call address (0x00) recognition. When multiple slave addresses are enabled, the actual address received may be read from the DAT register at the state where the own slave address has been received.

### 14.9.3 Address mask registers, MASK0 to MASK3

The four mask registers each contain seven active bits (7:1). Any bit in these registers which is set to '1' will cause an automatic compare on the corresponding bit of the received address when it is compared to the ADRn register associated with that mask register. In other words, bits in an ADRn register which are masked are not taken into account in determining an address match.

When an address-match interrupt occurs, the processor will have to read the data register (DAT) to determine what the received address was that actually caused the match.

## 14.9.4 Comparator

The comparator compares the received 7-bit slave address with its own slave address (7 most significant bits in ADR). It also compares the first received 8-bit byte with the General Call address (0x00). If an equality is found, the appropriate status bits are set and an interrupt is requested.

## 14.9.5 Shift register, DAT

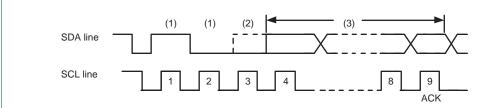

This 8-bit register contains a byte of serial data to be transmitted or a byte which has just been received. Data in DAT is always shifted from right to left; the first bit to be transmitted is the MSB (bit 7) and, after a byte has been received, the first bit of received data is located at the MSB of DAT. While data is being shifted out, data on the bus is simultaneously being shifted in; DAT always contains the last byte present on the bus. Thus, in the event of lost arbitration, the transition from master transmitter to slave receiver is made with the correct data in DAT.

## 14.9.6 Arbitration and synchronization logic

In the master transmitter mode, the arbitration logic checks that every transmitted logic 1 actually appears as a logic 1 on the  $I^2C$ -bus. If another device on the bus overrules a logic 1 and pulls the SDA line low, arbitration is lost, and the  $I^2C$  block immediately changes from master transmitter to slave receiver. The  $I^2C$  block will continue to output clock pulses (on SCL) until transmission of the current serial byte is complete.

Arbitration may also be lost in the master receiver mode. Loss of arbitration in this mode can only occur while the I<sup>2</sup>C block is returning a "not acknowledge: (logic 1) to the bus. Arbitration is lost when another device on the bus pulls this signal low. Since this can occur only at the end of a serial byte, the I<sup>2</sup>C block generates no further clock pulses. Figure 39 shows the arbitration procedure.

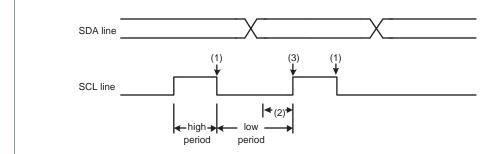

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- (1) Another device transmits serial data
- (2) Another device overrules a logic (dotted line) transmitted this I<sup>2</sup>C master by pulling the SDA line low. Arbitration is lost, and this I<sup>2</sup>C enters Slave Receiver mode.
- (3) This I<sup>2</sup>C is in Slave Receiver mode but still generates clock pulses until the current byte has been transmitted. This I<sup>2</sup>C will not generate clock pulses for the next byte. Data on SDA originates from the new master once it has won arbitration.

#### Fig 39. Arbitration procedure

The synchronization logic will synchronize the serial clock generator with the clock pulses on the SCL line from another device. If two or more master devices generate clock pulses, the "mark" duration is determined by the device that generates the shortest "marks," and the "space" duration is determined by the device that generates the longest "spaces". Figure 40 shows the synchronization procedure.

- (1) Another device pulls the SCL line low before this I<sup>2</sup>C has timed a complete high time. The other device effectively determines the (shorter) HIGH period.
- (2) Another device continues to pull the SCL line low after this I<sup>2</sup>C has timed a complete low time and released SCL. The I<sup>2</sup>C clock generator is forced to wait until SCL goes HIGH. The other device effectively determines the (longer) LOW period.
- (3) The SCL line is released, and the clock generator begins timing the HIGH time.

### Fig 40. Serial clock synchronization

A slave may stretch the space duration to slow down the bus master. The space duration may also be stretched for handshaking purposes. This can be done after each bit or after a complete byte transfer. the I<sup>2</sup>C block will stretch the SCL space duration after a byte has been transmitted or received and the acknowledge bit has been transferred. The serial interrupt flag (SI) is set, and the stretching continues until the serial interrupt flag is cleared.

#### 14.9.7 Serial clock generator

This programmable clock pulse generator provides the SCL clock pulses when the I<sup>2</sup>C block is in the master transmitter or master receiver mode. It is switched off when the I<sup>2</sup>C block is in slave mode. The I<sup>2</sup>C output clock frequency and duty cycle is programmable

UM10524

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

via the I<sup>2</sup>C Clock Control Registers. See the description of the I2CSCLL and I2CSCLH registers for details. The output clock pulses have a duty cycle as programmed unless the bus is synchronizing with other SCL clock sources as described above.

### 14.9.8 Timing and control

The timing and control logic generates the timing and control signals for serial byte handling. This logic block provides the shift pulses for DAT, enables the comparator, generates and detects START and STOP conditions, receives and transmits acknowledge bits, controls the master and slave modes, contains interrupt request logic, and monitors the I<sup>2</sup>C-bus status.

### 14.9.9 Control register, CONSET and CONCLR

The I<sup>2</sup>C control register contains bits used to control the following I<sup>2</sup>C block functions: start and restart of a serial transfer, termination of a serial transfer, bit rate, address recognition, and acknowledgment.

The contents of the I<sup>2</sup>C control register may be read as CONSET. Writing to CONSET will set bits in the I<sup>2</sup>C control register that correspond to ones in the value written. Conversely, writing to CONCLR will clear bits in the I<sup>2</sup>C control register that correspond to ones in the value written.

### 14.9.10 Status decoder and status register

The status decoder takes all of the internal status bits and compresses them into a 5-bit code. This code is unique for each I<sup>2</sup>C-bus status. The 5-bit code may be used to generate vector addresses for fast processing of the various service routines. Each service routine processes a particular bus status. There are 26 possible bus states if all four modes of the I<sup>2</sup>C block are used. The 5-bit status code is latched into the five most significant bits of the status register when the serial interrupt flag is set (by hardware) and remains stable until the interrupt flag is cleared by software. The three least significant bits of the status register are always zero. If the status code is used as a vector to service routines, then the routines are displaced by eight address locations. Eight bytes of code is sufficient for most of the service routines (see the software example in this section).

## 14.10 Details of I<sup>2</sup>C operating modes

The four operating modes are:

- Master Transmitter
- Master Receiver
- Slave Receiver
- Slave Transmitter

Data transfers in each mode of operation are shown in <u>Figure 41</u>, <u>Figure 42</u>, <u>Figure 43</u>, <u>Figure 44</u>, and <u>Figure 45</u>. <u>Table 259</u> lists abbreviations used in these figures when describing the I<sup>2</sup>C operating modes.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 259. Abbreviations used to describe an I<sup>2</sup>C operation

Abbreviation	Explanation
S	START Condition
SLA	7-bit slave address
R	Read bit (HIGH level at SDA)
W	Write bit (LOW level at SDA)
A	Acknowledge bit (LOW level at SDA)
Ā	Not acknowledge bit (HIGH level at SDA)
Data	8-bit data byte
Р	STOP condition

In Figure 41 to Figure 45, circles are used to indicate when the serial interrupt flag is set. The numbers in the circles show the status code held in the STAT register. At these points, a service routine must be executed to continue or complete the serial transfer. These service routines are not critical since the serial transfer is suspended until the serial interrupt flag is cleared by software.

When a serial interrupt routine is entered, the status code in STAT is used to branch to the appropriate service routine. For each status code, the required software action and details of the following serial transfer are given in tables from Table 261 to Table 267.

#### 14.10.1 Master Transmitter mode

In the master transmitter mode, a number of data bytes are transmitted to a slave receiver (see Figure 41). Before the master transmitter mode can be entered, I2CON must be initialized as follows:

Table 260. CONSET used to initialize Master Transmitter mode

Bit	7	6	5	4	3	2	1	0
Symbol	-	I2EN	STA	STO	SI	AA	-	-
Value	-	1	0	0	0	X	-	-

The I<sup>2</sup>C rate must also be configured in the SCLL and SCLH registers. I2EN must be set to logic 1 to enable the I<sup>2</sup>C block. If the AA bit is reset, the I<sup>2</sup>C block will not acknowledge its own slave address or the General Call address in the event of another device becoming master of the bus. In other words, if AA is reset, the I2C interface cannot enter slave mode. STA, STO, and SI must be reset.

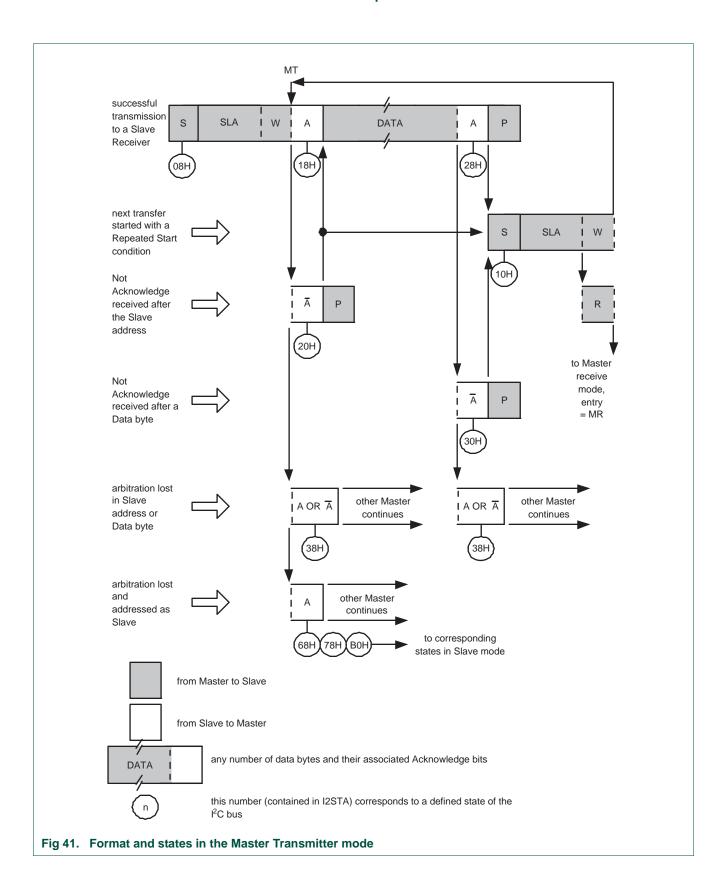

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

The master transmitter mode may now be entered by setting the STA bit. The I<sup>2</sup>C logic will now test the I<sup>2</sup>C-bus and generate a START condition as soon as the bus becomes free. When a START condition is transmitted, the serial interrupt flag (SI) is set, and the status code in the status register (STAT) will be 0x08. This status code is used by the interrupt service routine to enter the appropriate state service routine that loads DAT with the slave address and the data direction bit (SLA+W). The SI bit in CON must then be reset before the serial transfer can continue.

When the slave address and the direction bit have been transmitted and an acknowledgment bit has been received, the serial interrupt flag (SI) is set again, and a number of status codes in STAT are possible. There are 0x18, 0x20, or 0x38 for the master mode and also 0x68, 0x78, or 0xB0 if the slave mode was enabled (AA = logic 1). The appropriate action to be taken for each of these status codes is detailed in <a href="Table 261">Table 261</a>. After a Repeated START condition (state 0x10). The I<sup>2</sup>C block may switch to the master receiver mode by loading DAT with SLA+R).

Table 261. Master Transmitter mode

Status	Status of the I <sup>2</sup> C-bus	Application softw	are re	spons	е	Next action taken by I <sup>2</sup> C hardware

	bytes.	No DAT action	1	0	0	Х	A START condition will be transmitted when the bus becomes free.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

#### 14.10.2 Master Receiver mode

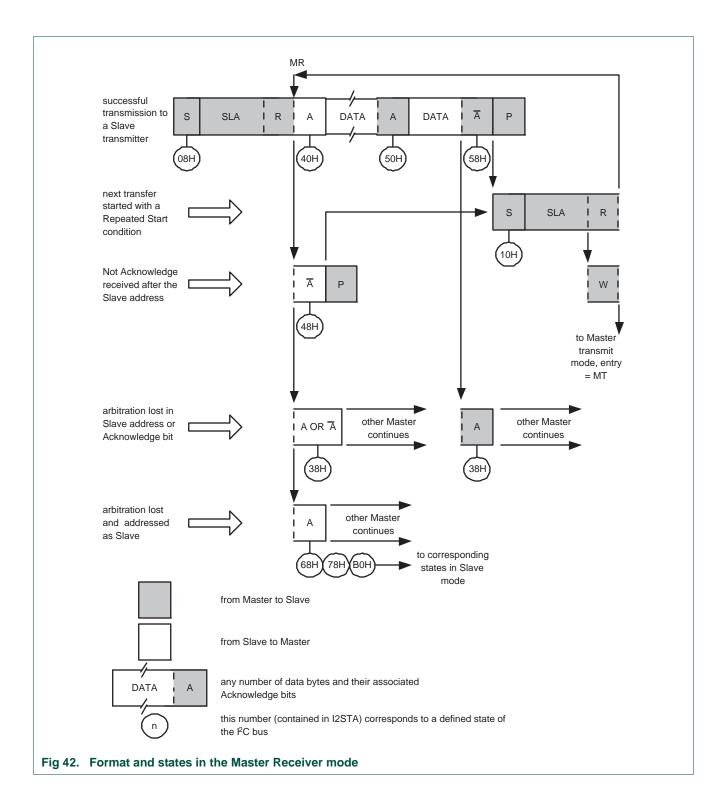

In the master receiver mode, a number of data bytes are received from a slave transmitter (see <u>Figure 42</u>). The transfer is initialized as in the master transmitter mode. When the START condition has been transmitted, the interrupt service routine must load DAT with the 7-bit slave address and the data direction bit (SLA+R). The SI bit in CON must then be cleared before the serial transfer can continue.

When the slave address and the data direction bit have been transmitted and an acknowledgment bit has been received, the serial interrupt flag (SI) is set again, and a number of status codes in STAT are possible. These are 0x40, 0x48, or 0x38 for the master mode and also 0x68, 0x78, or 0xB0 if the slave mode was enabled (AA = 1). The appropriate action to be taken for each of these status codes is detailed in <u>Table 262</u>. After a Repeated START condition (state 0x10), the I<sup>2</sup>C block may switch to the master transmitter mode by loading DAT with SLA+W.

Table 262. Master Receiver mode

Status	Status of the I <sup>2</sup> C-bus	Application softwa	are re	spons	е	Next action taken by I <sup>2</sup> C hardware	
Code	and hardware	To/From DAT	To C	ON			
(STAT)			STA	STO	SI	AA	
0x08	A START condition has been transmitted.	Load SLA+R	X	0	0	Χ	SLA+R will be transmitted; ACK bit will be received.
0x10	A Repeated START	Load SLA+R or	Χ	0	0	Χ	As above.
	condition has been transmitted.	Load SLA+W	Χ	0	0	Χ	SLA+W will be transmitted; the $I^2C$ block will be switched to MST/TRX mode.
0x38	Arbitration lost in NOT ACK bit.	No DAT action or	0	0	0	Х	I <sup>2</sup> C-bus will be released; the I <sup>2</sup> C block will enter slave mode.
		No DAT action	1	0	0	Х	A START condition will be transmitted when the bus becomes free.
0x40	SLA+R has been transmitted; ACK has	No DAT action or	0	0	0	0	Data byte will be received; NOT ACK bit will be returned.
	been received.	No DAT action	0	0	0	1	Data byte will be received; ACK bit will be returned.
0x48	SLA+R has been transmitted; NOT ACK	No DAT action or	1	0	0	X	Repeated START condition will be transmitted.
	has been received.	No DAT action or	0	1	0	X	STOP condition will be transmitted; STO flag will be reset.
		No DAT action	1	1	0	X	STOP condition followed by a START condition will be transmitted; STO flag will be reset.
0x50	Data byte has been received; ACK has	Read data byte or	0	0	0	0	Data byte will be received; NOT ACK bit will be returned.
	been returned.	Read data byte	0	0	0	1	Data byte will be received; ACK bit will be returned.
0x58	Data byte has been received; NOT ACK	Read data byte or	1	0	0	X	Repeated START condition will be transmitted.
	has been returned.	Read data byte or	0	1	0	Χ	STOP condition will be transmitted; STO flag will be reset.
		Read data byte	1	1	0	X	STOP condition followed by a START condition will be transmitted; STO flag will be reset.

#### 14.10.3 Slave Receiver mode

In the slave receiver mode, a number of data bytes are received from a master transmitter (see <u>Figure 43</u>). To initiate the slave receiver mode, ADR and CON must be loaded as follows:

Table 263. ADR usage in Slave Receiver mode

Bit	7	6	5	4	3	2	1	0
Symbol			OW	n slave 7-b	oit address			GC

The upper 7 bits are the address to which the I<sup>2</sup>C block will respond when addressed by a master. If the LSB (GC) is set, the I<sup>2</sup>C block will respond to the General Call address (0x00); otherwise it ignores the General Call address.

Table 264. CONSET used to initialize Slave Receiver mode

Bit	7	6	5	4	3	2	1	0
Symbol	-	I2EN	STA	STO	SI	AA	-	-
Value	-	1	0	0	0	1	-	-

The I<sup>2</sup>C-bus rate settings do not affect the I<sup>2</sup>C block in the slave mode. I2EN must be set to logic 1 to enable the I<sup>2</sup>C block. The AA bit must be set to enable the I<sup>2</sup>C block to acknowledge its own slave address or the General Call address. STA, STO, and SI must be reset.

When ADR and CON have been initialized, the I<sup>2</sup>C block waits until it is addressed by its own slave address followed by the data direction bit which must be "0" (W) for the I<sup>2</sup>C block to operate in the slave receiver mode. After its own slave address and the W bit have been received, the serial interrupt flag (SI) is set and a valid status code can be read from STAT. This status code is used to vector to a state service routine. The appropriate action to be taken for each of these status codes is detailed in <u>Table 265</u>. The slave receiver mode may also be entered if arbitration is lost while the I<sup>2</sup>C block is in the master mode (see status 0x68 and 0x78).

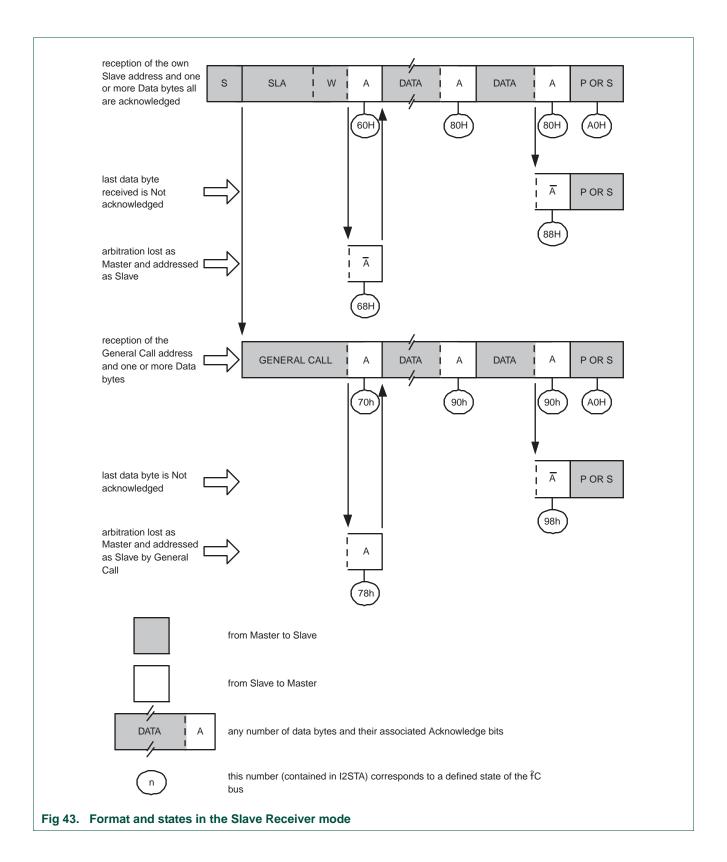

If the AA bit is reset during a transfer, the I<sup>2</sup>C block will return a not acknowledge (logic 1) to SDA after the next received data byte. While AA is reset, the I<sup>2</sup>C block does not respond to its own slave address or a General Call address. However, the I<sup>2</sup>C-bus is still monitored and address recognition may be resumed at any time by setting AA. This means that the AA bit may be used to temporarily isolate the I<sup>2</sup>C block from the I<sup>2</sup>C-bus.

Table 265. Slave Receiver mode

Status Code (STAT)	Status of the I <sup>2</sup> C-bus and hardware	Application softw	are re	spons	е		Next action taken by I <sup>2</sup> C hardware
		To/From DAT	То С	ON			
			STA	STO	SI	AA	
0x60	Own SLA+W has been received; ACK has been returned.	No DAT action or	Χ	0	0	0	Data byte will be received and NOT ACK will be returned.
		No DAT action	Χ	0	0	1	Data byte will be received and ACK will be returned.
0x68	Arbitration lost in SLA+R/W as master; Own SLA+W has been received, ACK returned.	No DAT action or	X	0	0	0	Data byte will be received and NOT ACK will be returned.
		No DAT action	Х	0	0	1	Data byte will be received and ACK will be returned.
0x70	General call address (0x00) has been received; ACK has been returned.	No DAT action or	Χ	0	0	0	Data byte will be received and NOT ACK will be returned.
		No DAT action	Χ	0	0	1	Data byte will be received and ACK will be returned.
0x78	Arbitration lost in SLA+R/W as master; General call address has been received, ACK has been returned.	No DAT action or	Χ	0	0	0	Data byte will be received and NOT ACK will be returned.
		No DAT action	X	0	0	1	Data byte will be received and ACK will be returned.
0x80	Previously addressed with own SLV address; DATA has been received; ACK has been returned.	Read data byte or	X	0	0	0	Data byte will be received and NOT ACK will be returned.
		Read data byte	X	0	0	1	Data byte will be received and ACK will be returned.
0x88	Previously addressed with own SLA; DATA byte has been received; NOT ACK has been returned.	Read data byte or	0	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address.
		Read data byte or	0	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General ca address will be recognized if ADR[0] = logic 1.
		Read data byte or	1	0	0	0	Switched to not addressed SLV mode; n recognition of own SLA or General call address. A START condition will be transmitted when the bus becomes free.
		Read data byte	1	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General can address will be recognized if ADR[0] = logic 1. A START condition will be transmitted when the bus becomes free.
0x90	Previously addressed with General Call; DATA byte has been received; ACK has been returned.	Read data byte or	Х	0	0	0	Data byte will be received and NOT ACK will be returned.
		Read data byte	X	0	0	1	Data byte will be received and ACK will be returned.

Table 265. Slave Receiver mode ...continued

Status Code (STAT)	Status of the I <sup>2</sup> C-bus and hardware	Application softw	are re	spons	е	Next action taken by I <sup>2</sup> C hardware	
		To/From DAT	To C	ON

		Read data byte or	0	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1.
		Read data byte or	1	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address. A START condition will be transmitted when the bus becomes free.
		Read data byte	1	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1. A START condition will be transmitted when the bus becomes free.
0xA0	A STOP condition or Repeated START condition has been received while still addressed as SLV/REC or SLV/TRX.	No STDAT action or	0	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address.
		No STDAT action or	0	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1.
		No STDAT action or	1	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address. A START condition will be transmitted when the bus becomes free.
		No STDAT action	1	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1. A START condition will be transmitted when the bus becomes free.

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

#### 14.10.4 Slave Transmitter mode

In the slave transmitter mode, a number of data bytes are transmitted to a master receiver (see Figure 44). Data transfer is initialized as in the slave receiver mode. When ADR and CON have been initialized, the I<sup>2</sup>C block waits until it is addressed by its own slave address followed by the data direction bit which must be "1" (R) for the I<sup>2</sup>C block to operate in the slave transmitter mode. After its own slave address and the R bit have been received, the serial interrupt flag (SI) is set and a valid status code can be read from STAT. This status code is used to vector to a state service routine, and the appropriate action to be taken for each of these status codes is detailed in Table 266. The slave transmitter mode may also be entered if arbitration is lost while the I<sup>2</sup>C block is in the master mode (see state 0xB0).

If the AA bit is reset during a transfer, the I<sup>2</sup>C block will transmit the last byte of the transfer and enter state 0xC0 or 0xC8. The I<sup>2</sup>C block is switched to the not addressed slave mode and will ignore the master receiver if it continues the transfer. Thus the master receiver receives all 1s as serial data. While AA is reset, the I<sup>2</sup>C block does not respond to its own slave address or a General Call address. However, the I<sup>2</sup>C-bus is still monitored, and address recognition may be resumed at any time by setting AA. This means that the AA bit may be used to temporarily isolate the I<sup>2</sup>C block from the I<sup>2</sup>C-bus.

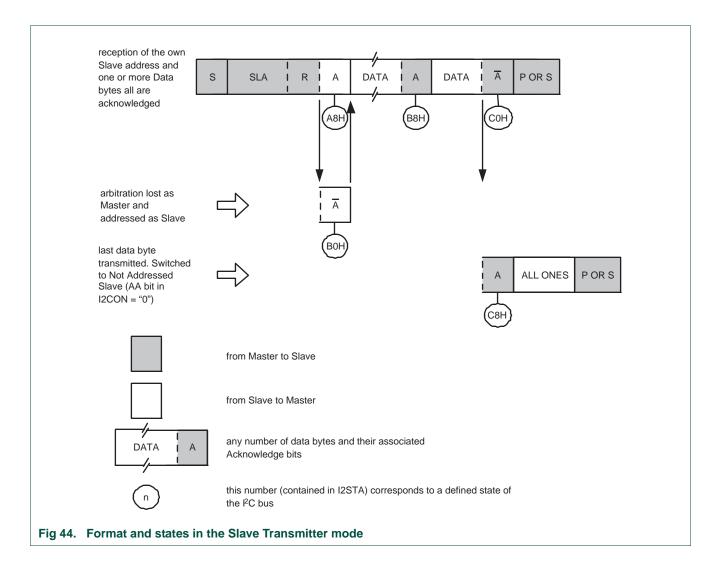

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

Table 266. Slave Transmitter mode

Status	Status of the I <sup>2</sup> C-bus	Application softw	Next action taken by I <sup>2</sup> C hardware				
Code (STAT)	and hardware	To/From DAT	То С	-			
			STA	STO	SI	AA	
0xA8	Own SLA+R has been received; ACK has been returned.	Load data byte or	Χ	0	0	0	Last data byte will be transmitted and ACK bit will be received.
		Load data byte	Χ	0	0	1	Data byte will be transmitted; ACK will be received.
0xB0	Arbitration lost in SLA+R/W as master; Own SLA+R has been received, ACK has been returned.	Load data byte or	Χ	0	0	0	Last data byte will be transmitted and ACK bit will be received.
		Load data byte	Χ	0	0	1	Data byte will be transmitted; ACK bit will be received.
0xB8	Data byte in DAT has been transmitted; ACK has been received.	Load data byte or	Χ	0	0	0	Last data byte will be transmitted and ACK bit will be received.
		Load data byte	Χ	0	0	1	Data byte will be transmitted; ACK bit will be received.
0xC0	Data byte in DAT has been transmitted; NOT ACK has been received.	No DAT action or	0	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address.
		No DAT action or	0	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1.
		No DAT action or	1	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address. A START condition will be transmitted when the bus becomes free.
		No DAT action	1	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1. A START condition will be transmitted when the bus becomes free.
0xC8	Last data byte in DAT has been transmitted (AA = 0); ACK has been received.	No DAT action or	0	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address.
		No DAT action or	0	0	0	1	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR[0] = logic 1.
		No DAT action or	1	0	0	0	Switched to not addressed SLV mode; no recognition of own SLA or General call address. A START condition will be transmitted when the bus becomes free.
		No DAT action	1	0	0	01	Switched to not addressed SLV mode; Own SLA will be recognized; General call address will be recognized if ADR.0 = logic 1. A START condition will be transmitted when the bus becomes free.

287 of 416

#### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

#### 14.10.5 Miscellaneous states

There are two STAT codes that do not correspond to a defined I<sup>2</sup>C hardware state (see Table 267). These are discussed below.

#### 14.10.5.1 STAT = 0xF8

This status code indicates that no relevant information is available because the serial interrupt flag, SI, is not yet set. This occurs between other states and when the I<sup>2</sup>C block is not involved in a serial transfer.

### 14.10.5.2 STAT = 0x00

This status code indicates that a bus error has occurred during an I<sup>2</sup>C serial transfer. A bus error is caused when a START or STOP condition occurs at an illegal position in the format frame. Examples of such illegal positions are during the serial transfer of an address byte, a data byte, or an acknowledge bit. A bus error may also be caused when external interference disturbs the internal I<sup>2</sup>C block signals. When a bus error occurs, SI is set. To recover from a bus error, the STO flag must be set and SI must be cleared. This

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

causes the I<sup>2</sup>C block to enter the "not addressed" slave mode (a defined state) and to clear the STO flag (no other bits in CON are affected). The SDA and SCL lines are released (a STOP condition is not transmitted).

Table 267. Miscellaneous States

Status Code (STAT)	Status of the I <sup>2</sup> C-bus and hardware	Application softw To/From DAT	То С	-		AA	Next action taken by I <sup>2</sup> C hardware
0xF8	No relevant state information available; SI = 0.	No DAT action	١	No COI	N actio	on	Wait or proceed current transfer.
0x00	Bus error during MST or selected slave modes, due to an illegal START or STOP condition. State 0x00 can also occur when interference causes the I <sup>2</sup> C block to enter an undefined state.	No DAT action	0	1	0	X	Only the internal hardware is affected in the MST or addressed SLV modes. In all cases, the bus is released and the I <sup>2</sup> C block is switched to the not addressed SLV mode. STO is reset.

# 14.10.6 Some special cases

The I<sup>2</sup>C hardware has facilities to handle the following special cases that may occur during a serial transfer:

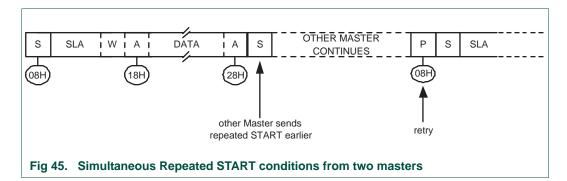

- Simultaneous Repeated START conditions from two masters
- · Data transfer after loss of arbitration
- Forced access to the I<sup>2</sup>C-bus
- I<sup>2</sup>C-bus obstructed by a LOW level on SCL or SDA
- Bus error

### 14.10.6.1 Simultaneous Repeated START conditions from two masters

A Repeated START condition may be generated in the master transmitter or master receiver modes. A special case occurs if another master simultaneously generates a Repeated START condition (see <u>Figure 45</u>). Until this occurs, arbitration is not lost by either master since they were both transmitting the same data.

If the  $I^2C$  hardware detects a Repeated START condition on the  $I^2C$ -bus before generating a Repeated START condition itself, it will release the bus, and no interrupt request is generated. If another master frees the bus by generating a STOP condition, the  $I^2C$  block will transmit a normal START condition (state 0x08), and a retry of the total serial data transfer can commence.

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

### 14.10.6.2 Data transfer after loss of arbitration

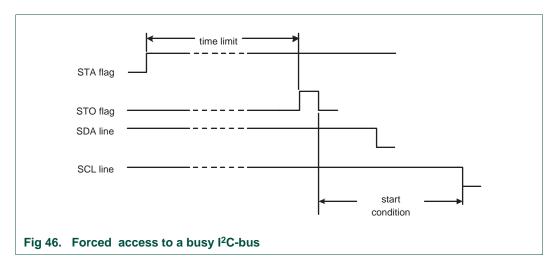

Arbitration may be lost in the master transmitter and master receiver modes (see <u>Figure 39</u>). Loss of arbitration is indicated by the following states in STAT; 0x38, 0x68, 0x78, and 0xB0 (see <u>Figure 41</u> and <u>Figure 42</u>).

If the STA flag in CON is set by the routines which service these states, then, if the bus is free again, a START condition (state 0x08) is transmitted without intervention by the CPU, and a retry of the total serial transfer can commence.

### 14.10.6.3 Forced access to the l<sup>2</sup>C-bus

In some applications, it may be possible for an uncontrolled source to cause a bus hang-up. In such situations, the problem may be caused by interference, temporary interruption of the bus or a temporary short-circuit between SDA and SCL.

If an uncontrolled source generates a superfluous START or masks a STOP condition, then the I<sup>2</sup>C-bus stays busy indefinitely. If the STA flag is set and bus access is not obtained within a reasonable amount of time, then a forced access to the I<sup>2</sup>C-bus is possible. This is achieved by setting the STO flag while the STA flag is still set. No STOP condition is transmitted. The I<sup>2</sup>C hardware behaves as if a STOP condition was received and is able to transmit a START condition. The STO flag is cleared by hardware (see Figure 46).

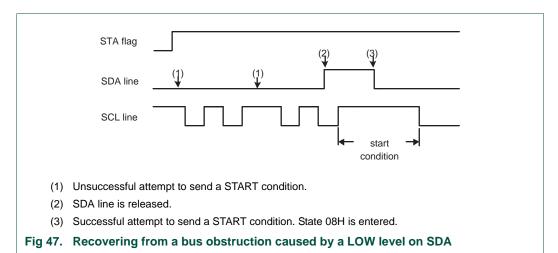

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

# 14.10.6.4 I<sup>2</sup>C-bus obstructed by a LOW level on SCL or SDA

An I<sup>2</sup>C-bus hang-up can occur if either the SDA or SCL line is held LOW by any device on the bus. If the SCL line is obstructed (pulled LOW) by a device on the bus, no further serial transfer is possible, and the problem must be resolved by the device that is pulling the SCL bus line LOW.

Typically, the SDA line may be obstructed by another device on the bus that has become out of synchronization with the current bus master by either missing a clock, or by sensing a noise pulse as a clock. In this case, the problem can be solved by transmitting additional clock pulses on the SCL line (see Figure 47). The I<sup>2</sup>C interface does not include a dedicated time-out timer to detect an obstructed bus, but this can be implemented using another timer in the system. When detected, software can force clocks (up to 9 may be required) on SCL until SDA is released by the offending device. At that point, the slave may still be out of synchronization, so a START should be generated to insure that all I<sup>2</sup>C peripherals are synchronized.

### 14.10.6.5 Bus error

A bus error occurs when a START or STOP condition is detected at an illegal position in the format frame. Examples of illegal positions are during the serial transfer of an address byte, a data bit, or an acknowledge bit.

The I<sup>2</sup>C hardware only reacts to a bus error when it is involved in a serial transfer either as a master or an addressed slave. When a bus error is detected, the I<sup>2</sup>C block immediately switches to the not addressed slave mode, releases the SDA and SCL lines, sets the interrupt flag, and loads the status register with 0x00. This status code may be used to vector to a state service routine which either attempts the aborted serial transfer again or simply recovers from the error condition as shown in Table 267.

### 14.10.7 I<sup>2</sup>C state service routines

This section provides examples of operations that must be performed by various I<sup>2</sup>C state service routines. This includes:

- Initialization of the I<sup>2</sup>C block after a Reset.
- I<sup>2</sup>C Interrupt Service
- The 26 state service routines providing support for all four I<sup>2</sup>C operating modes.

UM10524

**User manual** 

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

### 14.10.8 Initialization

In the initialization example, the I<sup>2</sup>C block is enabled for both master and slave modes. For each mode, a buffer is used for transmission and reception. The initialization routine performs the following functions:

- ADR is loaded with the part's own slave address and the General Call bit (GC)
- The I<sup>2</sup>C interrupt enable and interrupt priority bits are set
- The slave mode is enabled by simultaneously setting the I2EN and AA bits in CON and the serial clock frequency (for master modes) is defined by is defined by loading the SCLH and SCLL registers. The master routines must be started in the main program.

The I<sup>2</sup>C hardware now begins checking the I<sup>2</sup>C-bus for its own slave address and General Call. If the General Call or the own slave address is detected, an interrupt is requested and STAT is loaded with the appropriate state information.

# 14.10.9 I<sup>2</sup>C interrupt service

When the I<sup>2</sup>C interrupt is entered, STAT contains a status code which identifies one of the 26 state services to be executed.

### 14.10.10 The state service routines

Each state routine is part of the I<sup>2</sup>C interrupt routine and handles one of the 26 states.

# 14.10.11 Adapting state services to an application

The state service examples show the typical actions that must be performed in response to the 26 I<sup>2</sup>C state codes. If one or more of the four I<sup>2</sup>C operating modes are not used, the associated state services can be omitted, as long as care is taken that the those states can never occur.

In an application, it may be desirable to implement some kind of time-out during I<sup>2</sup>C operations, in order to trap an inoperative bus or a lost service routine.

# 14.11 Software example

### 14.11.1 Initialization routine

Example to initialize I<sup>2</sup>C Interface as a Slave and/or Master.

- 1. Load ADR with own Slave Address, enable General Call recognition if needed.
- 2. Enable I<sup>2</sup>C interrupt.
- 3. Write 0x44 to CONSET to set the I2EN and AA bits, enabling Slave functions. For Master only functions, write 0x40 to CONSET.

### 14.11.2 Start Master Transmit function

Begin a Master Transmit operation by setting up the buffer, pointer, and data count, then initiating a START.

1. Initialize Master data counter.

292 of 416

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 2. Set up the Slave Address to which data will be transmitted, and add the Write bit.
- 3. Write 0x20 to CONSET to set the STA bit.
- 4. Set up data to be transmitted in Master Transmit buffer.
- 5. Initialize the Master data counter to match the length of the message being sent.
- 6. Exit

### 14.11.3 Start Master Receive function

Begin a Master Receive operation by setting up the buffer, pointer, and data count, then initiating a START.

- 1. Initialize Master data counter.
- 2. Set up the Slave Address to which data will be transmitted, and add the Read bit.
- Write 0x20 to CONSET to set the STA bit.
- 4. Set up the Master Receive buffer.
- 5. Initialize the Master data counter to match the length of the message to be received.
- 6. Exit

# 14.11.4 I<sup>2</sup>C interrupt routine

Determine the I<sup>2</sup>C state and which state routine will be used to handle it.

- 1. Read the I<sup>2</sup>C status from STA.
- 2. Use the status value to branch to one of 26 possible state routines.

# 14.11.5 Non mode specific states

### 14.11.5.1 State: 0x00

Bus Error. Enter not addressed Slave mode and release bus.

- 1. Write 0x14 to CONSET to set the STO and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

### 14.11.5.2 Master States

State 08 and State 10 are for both Master Transmit and Master Receive modes. The R/W bit decides whether the next state is within Master Transmit mode or Master Receive mode.

#### 14.11.5.3 State: 0x08

A START condition has been transmitted. The Slave Address + R/W bit will be transmitted, an ACK bit will be received.

- 1. Write Slave Address with R/W bit to DAT.
- 2. Write 0x04 to CONSET to set the AA bit.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Set up Master Transmit mode data buffer.

UM10524

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 5. Set up Master Receive mode data buffer.
- 6. Initialize Master data counter.
- 7. Exit

### 14.11.5.4 State: 0x10

A Repeated START condition has been transmitted. The Slave Address + R/W bit will be transmitted, an ACK bit will be received.

- 1. Write Slave Address with R/W bit to DAT.
- 2. Write 0x04 to CONSET to set the AA bit.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- Set up Master Transmit mode data buffer.
- 5. Set up Master Receive mode data buffer.
- 6. Initialize Master data counter.
- 7. Exit

#### 14.11.6 Master Transmitter states

### 14.11.6.1 State: 0x18

Previous state was State 8 or State 10, Slave Address + Write has been transmitted, ACK has been received. The first data byte will be transmitted, an ACK bit will be received.

- 1. Load DAT with first data byte from Master Transmit buffer.
- 2. Write 0x04 to CONSET to set the AA bit.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Increment Master Transmit buffer pointer.
- 5. Exit

#### 14.11.6.2 State: 0x20

Slave Address + Write has been transmitted, NOT ACK has been received. A STOP condition will be transmitted.

- 1. Write 0x14 to CONSET to set the STO and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

# 14.11.6.3 State: 0x28

Data has been transmitted, ACK has been received. If the transmitted data was the last data byte then transmit a STOP condition, otherwise transmit the next data byte.

- 1. Decrement the Master data counter, skip to step 5 if not the last data byte.
- 2. Write 0x14 to CONSET to set the STO and AA bits.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Exit
- 5. Load DAT with next data byte from Master Transmit buffer.

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 6. Write 0x04 to CONSET to set the AA bit.
- 7. Write 0x08 to CONCLR to clear the SI flag.
- 8. Increment Master Transmit buffer pointer
- 9. Exit

### 14.11.6.4 State: 0x30

Data has been transmitted. NOT ACK received. A STOP condition will be transmitted.

- 1. Write 0x14 to CONSET to set the STO and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

#### 14.11.6.5 State: 0x38

Arbitration has been lost during Slave Address + Write or data. The bus has been released and not addressed Slave mode is entered. A new START condition will be transmitted when the bus is free again.

- 1. Write 0x24 to CONSET to set the STA and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

# 14.11.7 Master Receive states

# 14.11.7.1 State: 0x40

Previous state was State 08 or State 10. Slave Address + Read has been transmitted, ACK has been received. Data will be received and ACK returned.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

### 14.11.7.2 State: 0x48

Slave Address + Read has been transmitted, NOT ACK has been received. A STOP condition will be transmitted.

- 1. Write 0x14 to CONSET to set the STO and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

### 14.11.7.3 State: 0x50

Data has been received, ACK has been returned. Data will be read from DAT. Additional data will be received. If this is the last data byte then NOT ACK will be returned, otherwise ACK will be returned.

- 1. Read data byte from DAT into Master Receive buffer.
- 2. Decrement the Master data counter, skip to step 5 if not the last data byte.
- 3. Write 0x0C to CONCLR to clear the SI flag and the AA bit.

UM10524

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 4. Exit
- 5. Write 0x04 to CONSET to set the AA bit.
- 6. Write 0x08 to CONCLR to clear the SI flag.
- 7. Increment Master Receive buffer pointer
- 8. Exit

### 14.11.7.4 State: 0x58

Data has been received, NOT ACK has been returned. Data will be read from DAT. A STOP condition will be transmitted.

- 1. Read data byte from DAT into Master Receive buffer.
- 2. Write 0x14 to CONSET to set the STO and AA bits.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Exit

### 14.11.8 Slave Receiver states

### 14.11.8.1 State: 0x60

Own Slave Address + Write has been received, ACK has been returned. Data will be received and ACK returned.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Set up Slave Receive mode data buffer.
- 4. Initialize Slave data counter.
- 5. Exit

#### 14.11.8.2 State: 0x68

Arbitration has been lost in Slave Address and R/W bit as bus Master. Own Slave Address + Write has been received, ACK has been returned. Data will be received and ACK will be returned. STA is set to restart Master mode after the bus is free again.

- 1. Write 0x24 to CONSET to set the STA and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Set up Slave Receive mode data buffer.
- 4. Initialize Slave data counter.
- 5. Exit.

### 14.11.8.3 State: 0x70

General call has been received, ACK has been returned. Data will be received and ACK returned.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Set up Slave Receive mode data buffer.

UM10524

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 4. Initialize Slave data counter.
- 5. Exit

#### 14.11.8.4 State: 0x78

Arbitration has been lost in Slave Address + R/W bit as bus Master. General call has been received and ACK has been returned. Data will be received and ACK returned. STA is set to restart Master mode after the bus is free again.

- 1. Write 0x24 to CONSET to set the STA and AA bits.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Set up Slave Receive mode data buffer.
- 4. Initialize Slave data counter.
- 5. Exit

### 14.11.8.5 State: 0x80

Previously addressed with own Slave Address. Data has been received and ACK has been returned. Additional data will be read.

- 1. Read data byte from DAT into the Slave Receive buffer.
- 2. Decrement the Slave data counter, skip to step 5 if not the last data byte.
- 3. Write 0x0C to CONCLR to clear the SI flag and the AA bit.
- 4. Exit.
- 5. Write 0x04 to CONSET to set the AA bit.
- 6. Write 0x08 to CONCLR to clear the SI flag.
- 7. Increment Slave Receive buffer pointer.
- 8. Exit

#### 14.11.8.6 State: 0x88

Previously addressed with own Slave Address. Data has been received and NOT ACK has been returned. Received data will not be saved. Not addressed Slave mode is entered.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

### 14.11.8.7 State: 0x90

Previously addressed with General Call. Data has been received, ACK has been returned. Received data will be saved. Only the first data byte will be received with ACK. Additional data will be received with NOT ACK.

- 1. Read data byte from DAT into the Slave Receive buffer.
- 2. Write 0x0C to CONCLR to clear the SI flag and the AA bit.
- 3. Exit

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

#### 14.11.8.8 State: 0x98

Previously addressed with General Call. Data has been received, NOT ACK has been returned. Received data will not be saved. Not addressed Slave mode is entered.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

#### 14.11.8.9 State: 0xA0

A STOP condition or Repeated START has been received, while still addressed as a Slave. Data will not be saved. Not addressed Slave mode is entered.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

### 14.11.9 Slave Transmitter states

# 14.11.9.1 State: 0xA8

Own Slave Address + Read has been received, ACK has been returned. Data will be transmitted, ACK bit will be received.

- 1. Load DAT from Slave Transmit buffer with first data byte.
- 2. Write 0x04 to CONSET to set the AA bit.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Set up Slave Transmit mode data buffer.
- 5. Increment Slave Transmit buffer pointer.
- 6. Exit

#### 14.11.9.2 State: 0xB0

Arbitration lost in Slave Address and R/W bit as bus Master. Own Slave Address + Read has been received, ACK has been returned. Data will be transmitted, ACK bit will be received. STA is set to restart Master mode after the bus is free again.

- 1. Load DAT from Slave Transmit buffer with first data byte.
- 2. Write 0x24 to CONSET to set the STA and AA bits.
- Write 0x08 to CONCLR to clear the SI flag.
- 4. Set up Slave Transmit mode data buffer.
- 5. Increment Slave Transmit buffer pointer.
- 6. Exit

### 14.11.9.3 State: 0xB8

Data has been transmitted, ACK has been received. Data will be transmitted, ACK bit will be received.

Load DAT from Slave Transmit buffer with data byte.

UM10524

### Chapter 14: LPC1315/16/17/45/46/47 I2C-bus controller

- 2. Write 0x04 to CONSET to set the AA bit.
- 3. Write 0x08 to CONCLR to clear the SI flag.
- 4. Increment Slave Transmit buffer pointer.
- 5. Exit

### 14.11.9.4 State: 0xC0

Data has been transmitted, NOT ACK has been received. Not addressed Slave mode is entered.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit.

### 14.11.9.5 State: 0xC8

The last data byte has been transmitted, ACK has been received. Not addressed Slave mode is entered.

- 1. Write 0x04 to CONSET to set the AA bit.
- 2. Write 0x08 to CONCLR to clear the SI flag.
- 3. Exit

# UM10524

# Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer (WWDT)

Rev. 4 — 12 March 2013

**User manual** 

# 15.1 How to read this chapter

The WWDT is identical on all LPC1315/16/17/45/46/47 parts.

# 15.2 Basic configuration

The WWDT is configured through the following registers:

- Power to the register interface (WWDT PCLK clock): In the SYSAHBCLKCTRL register, set bit 15 in <u>Table 19</u>.
- Enable the WWDT clock source (the watchdog oscillator or the IRC) in the PDRUNCFG register (Table 42).
- If needed, enable the watchdog interrupt for wake-up in the STARTERP1 register (Table 39).

# 15.3 Features

- Internally resets chip if not reloaded during the programmable time-out period.
- Optional windowed operation requires reload to occur between a minimum and maximum time-out period, both programmable.
- Optional warning interrupt can be generated at a programmable time prior to watchdog time-out.
- Programmable 24-bit timer with internal fixed pre-scaler.
- Selectable time period from 1,024 watchdog clocks ( $T_{WDCLK} \times 256 \times 4$ ) to over 67 million watchdog clocks ( $T_{WDCLK} \times 2^{24} \times 4$ ) in increments of 4 watchdog clocks.
- "Safe" watchdog operation. Once enabled, requires a hardware reset or a Watchdog reset to be disabled.
- Incorrect feed sequence causes immediate watchdog event if enabled.
- The watchdog reload value can optionally be protected such that it can only be changed after the "warning interrupt" time is reached.
- Flag to indicate Watchdog reset.
- The Watchdog clock (WDCLK) source can be selected as the Internal High frequency oscillator (IRC) or the WatchDog oscillator.
- The Watchdog timer can be configured to run in Deep-sleep or Power-down mode when using the watchdog oscillator as the clock source.
- Debug mode.

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

# 15.4 Applications

The purpose of the Watchdog Timer is to reset or interrupt the microcontroller within a programmable time if it enters an erroneous state. When enabled, a watchdog reset and/or will be generated if the user program fails to "feed" (reload) the Watchdog within a predetermined amount of time.

When a watchdog window is programmed, an early watchdog feed is also treated as a watchdog event. This allows preventing situations where a system failure may still feed the watchdog. For example, application code could be stuck in an interrupt service that contains a watchdog feed. Setting the window such that this would result in an early feed will generate a watchdog event, allowing for system recovery.

# 15.5 Description

The Watchdog consists of a fixed (divide by 4) pre-scaler and a 24 bit counter which decrements when clocked. The minimum value from which the counter decrements is 0xFF. Setting a value lower than 0xFF causes 0xFF to be loaded in the counter. Hence the minimum Watchdog interval is ( $T_{WDCLK} \times 256 \times 4$ ) and the maximum Watchdog interval is ( $T_{WDCLK} \times 2^{24} \times 4$ ) in multiples of ( $T_{WDCLK} \times 4$ ). The Watchdog should be used in the following manner:

- Set the Watchdog timer constant reload value in the TC register.
- Set the Watchdog timer operating mode in the MOD register.
- Set a value for the watchdog window time in the WINDOW register if windowed operation is desired.
- Set a value for the watchdog warning interrupt in the WARNINT register if a warning interrupt is desired.
- Enable the Watchdog by writing 0xAA followed by 0x55 to the FEED register.
- The Watchdog must be fed again before the Watchdog counter reaches zero in order to prevent a watchdog event. If a window value is programmed, the feed must also occur after the watchdog counter passes that value.

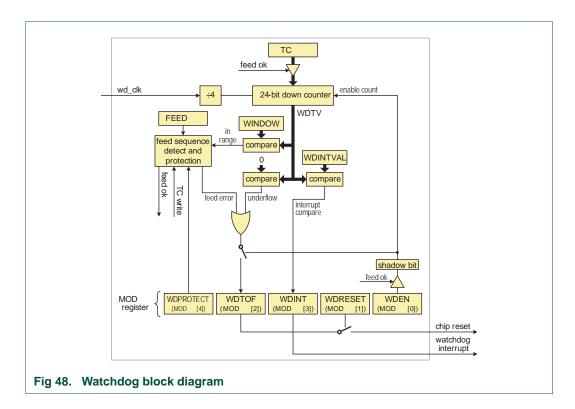

When the Watchdog Timer is configured so that a watchdog event will cause a reset and the counter reaches zero, the CPU will be reset, loading the stack pointer and program counter from the vector table as for an external reset. The Watchdog time-out flag (WDTOF) can be examined to determine if the Watchdog has caused the reset condition. The WDTOF flag must be cleared by software.

When the Watchdog Timer is configured to generate a warning interrupt, the interrupt will occur when the counter matches the value defined by the WARNINT register.

# 15.5.1 Block diagram

The block diagram of the Watchdog is shown below in the <u>Figure 48</u>. The synchronization logic (PCLK - WDCLK) is not shown in the block diagram.

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

# 15.6 Clocking and power control

The watchdog timer block uses two clocks: PCLK and WDCLK. PCLK is used for the APB accesses to the watchdog registers and is derived from the system clock (see <a href="Figure 3">Figure 3</a>). The WDCLK is used for the watchdog timer counting and is derived from the wdt\_clk in <a href="Figure 3">Figure 3</a>. Either the IRC or the watchdog oscillator can be used as wdt\_clk in Active mode or Sleep mode, but in Deep-sleep or Power-down modes only the watchdog oscillator is available.

**Remark:** If the LOCK bit is set in the MOD register (<u>Table 269</u>) and the IRC is selected as a clock source for the WWDT, the IRC is forced on during Deep-sleep and Power-down modes resulting in increased power consumption.

There is some synchronization logic between these two clock domains. When the MOD and TC registers are updated by APB operations, the new value will take effect in 3 WDCLK cycles on the logic in the WDCLK clock domain. When the watchdog timer is counting on WDCLK, the synchronization logic will first lock the value of the counter on WDCLK and then synchronize it with the PCLK for reading as the WDTV register by the CPU.

302 of 416

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

# 15.7 Using the WWDT lock features

The WWDT supports several lock features which can be enabled to ensure that the WWDT is running at all times:

- Accidental overwrite of the WWDT clock source
- Changing the WWDT clock source
- Changing the WWDT reload value

## 15.7.1 Accidental overwrite of the WWDT clock

If bit 31 of the WWDT CLKSEL register (<u>Table 274</u>) is set, writes to bit 0 of the CLKSEL register, the clock source select bit, will be ignored and the clock source will not change.

The clock source overwrite lock mechanism can simply be disabled by clearing bit 31 in the CLKSEL register.

# 15.7.2 Changing the WWDT clock source

If bit 5 in the WWDT MOD register is set, the current clock source as selected in the CLKSEL register is locked and can not be changed either by software or by hardware when Sleep, Deep-sleep or Power-down modes are entered. Therefore, the user must ensure that the appropriate WWDT clock source for each power mode is selected **before** setting bit 5 in the MOD register:

- Active or Sleep modes: Both the IRC or the watchdog oscillator are allowed.
- Deep-sleep mode: Both the IRC and the watchdog oscillator are allowed. However, using the IRC during Deep-sleep mode will increase the power consumption. To minimize power consumption, use the watchdog oscillator as clock source.
- Power-down mode: Only the watchdog oscillator is allowed as clock source for the WWDT. Therefore, before setting bit 5 and locking the clock source, the WWDT clock source must be set to the watchdog oscillator. Otherwise, the part may not be able to enter Power-down mode.
- Deep power-down mode: No clock locking mechanisms are in effect as neither the WWDT nor any of the clocks are running. However, an additional lock bit in the PMU can be set to prevent the part from even entering Deep power-down mode (see Table 48).

The clock source lock mechanism can only be disabled by a reset of any type.

### 15.7.3 Changing the WWDT reload value

If bit 4 is set in the WWDT MOD register, the watchdog time-out value (TC) can be changed only after the counter is below the value of WDWARNINT and WDWINDOW.

The reload overwrite lock mechanism can only be disabled by a reset of any type.

# Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

# 15.8 Register description

The Watchdog Timer contains the registers shown in Table 268.

Table 268. Register overview: Watchdog timer (base address 0x4000 4000)

Name	Access	Address offset	Description	Reset Value <sup>[1]</sup>	Reference
MOD	R/W	0x000	Watchdog mode register. This register contains the basic mode and status of the Watchdog Timer.	0	Table 269
TC	R/W	0x004	Watchdog timer constant register. This 24-bit register determines the time-out value.	0xFF	Table 271
FEED	WO	0x008	Watchdog feed sequence register. Writing 0xAA followed by 0x55 to this register reloads the Watchdog timer with the value contained in WDTC.	NA	Table 272
TV	RO	0x00C	Watchdog timer value register. This 24-bit register reads out the current value of the Watchdog timer.	0xFF	Table 273
CLKSEL	R/W	0x010	Watchdog clock select register.	0	Table 273
WARNINT	R/W	0x014	Watchdog Warning Interrupt compare value.	0	Table 275
WINDOW	R/W	0x018	Watchdog Window compare value.	0xFF FFFF	Table 276

<sup>[1]</sup> Reset Value reflects the data stored in used bits only. It does not include reserved bits content.

# 15.8.1 Watchdog mode register

The WDMOD register controls the operation of the Watchdog. Note that a watchdog feed must be performed before any changes to the WDMOD register take effect.

Table 269. Watchdog mode register (MOD - 0x4000 4000) bit description

Bit	Symbol	Value	Description	Reset value
0	WDEN		Watchdog enable bit. Once this bit has been written with a 1 it cannot be rewritten with a 0.	0
		0	The watchdog timer is stopped.	
		1	The watchdog timer is running.	
1	WDRESET		Watchdog reset enable bit. Once this bit has been written with a 1 it cannot be rewritten with a 0.	0
		0	A watchdog timeout will not cause a chip reset.	
		1	A watchdog timeout will cause a chip reset.	
2	WDTOF		Watchdog time-out flag. Set when the watchdog timer times out, by a feed error, or by events associated with WDPROTECT. Cleared by software. Causes a chip reset if WDRESET = 1.	0 (only after external reset)
3	WDINT		Warning interrupt flag. Set when the timer reaches the value in WDWARNINT. Cleared by software.	0

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

Table 269. Watchdog mode register (MOD - 0x4000 4000) bit description

Bit	Symbol	Value	Description	Reset value
4	WDPROTECT		Watchdog update mode. This bit can be set once by software and is only cleared by a reset.	0
		0	The watchdog time-out value (TC) can be changed at any time.	
		1	The watchdog time-out value (TC) can be changed only after the counter is below the value of WDWARNINT and WDWINDOW.	
5	LOCK		A 1 in this bit prevents disabling or powering down the clock source selected by bit 0 of the WDCLKSRC register and also prevents switching to a clock source that is disabled or powered down. This bit can be set once by software and is only cleared by any reset.	0
			<b>Remark:</b> If this bit is one and the WWDT clock source is the IRC when Deep-sleep or Power-down modes are entered, the IRC remains running thereby increasing power consumption in Deep-sleep mode and potentially preventing the part from entering Power-down mode correctly (see <u>Section 15.7</u> ).	
31:6	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

Once the **WDEN**, **WDPROTECT**, or **WDRESET** bits are set they can not be cleared by software. Both flags are cleared by an external reset or a Watchdog timer reset.

**WDTOF** The Watchdog time-out flag is set when the Watchdog times out, when a feed error occurs, or when PROTECT =1 and an attempt is made to write to the TC register. This flag is cleared by software writing a 0 to this bit.

**WDINT** The Watchdog interrupt flag is set when the Watchdog counter reaches the value specified by WARNINT. This flag is cleared when any reset occurs, and is cleared by software by writing a 0 to this bit.

In all power modes except Deep power-down mode, a Watchdog reset or interrupt can occur when the watchdog is running and has an operating clock source. The watchdog oscillator or the IRC can be selected to keep running in Sleep and Deep-sleep modes. In Power-down mode, only the watchdog oscillator is allowed. If a watchdog interrupt occurs in Sleep, Deep-sleep mode, or Power-down mode and the WWDT interrupt is enabled in the NVIC, the device will wake up. Note that in Deep-sleep and Power-down modes, the WWDT interrupt must be enabled in the STARTERP1 register in addition to the NVIC.

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

Table 270. Watchdog operating modes selection

WDEN	WDRESET	Mode of Operation
0	X (0 or 1)	Debug/Operate without the Watchdog running.
1	0	Watchdog interrupt mode: the watchdog warning interrupt will be generated but watchdog reset will not.
		When this mode is selected, the watchdog counter reaching the value specified by WDWARNINT will set the WDINT flag and the Watchdog interrupt request will be generated.
1	1	Watchdog reset mode: both the watchdog interrupt and watchdog reset are enabled.
		When this mode is selected, the watchdog counter reaching the value specified by WDWARNINT will set the WDINT flag and the Watchdog interrupt request will be generated, and the watchdog counter reaching zero will reset the microcontroller. A watchdog feed prior to reaching the value of WDWINDOW will also cause a watchdog reset.

# 15.8.2 Watchdog Timer Constant register

The TC register determines the time-out value. Every time a feed sequence occurs the value in the TC is loaded into the Watchdog timer. The TC resets to 0x00 00FF. Writing a value below 0xFF will cause 0x00 00FF to be loaded into the TC. Thus the minimum time-out interval is  $T_{WDCLK} \times 256 \times 4$ .

If the WDPROTECT bit in WDMOD = 1, an attempt to change the value of TC before the watchdog counter is below the values of WDWARNINT and WDWINDOW will cause a watchdog reset and set the WDTOF flag.

Table 271. Watchdog Timer Constant register (TC - 0x4000 4004) bit description

Bit	Symbol	Description	Reset Value
23:0	COUNT	Watchdog time-out value.	0x00 00FF
31:24	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

## 15.8.3 Watchdog Feed register

Writing 0xAA followed by 0x55 to this register will reload the Watchdog timer with the WDTC value. This operation will also start the Watchdog if it is enabled via the WDMOD register. Setting the WDEN bit in the WDMOD register is not sufficient to enable the Watchdog. A valid feed sequence must be completed after setting WDEN before the Watchdog is capable of generating a reset. Until then, the Watchdog will ignore feed errors.

After writing 0xAA to WDFEED, access to any Watchdog register other than writing 0x55 to WDFEED causes an immediate reset/interrupt when the Watchdog is enabled, and sets the WDTOF flag. The reset will be generated during the second PCLK following an incorrect access to a Watchdog register during a feed sequence.

It is good practise to disable interrupts around a feed sequence, if the application is such that some/any interrupt might result in rescheduling processor control away from the current task in the middle of the feed, and then lead to some other access to the WDT before control is returned to the interrupted task.

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

Table 272. Watchdog Feed register (FEED - 0x4000 4008) bit description

Bit	Symbol	Description	Reset Value
7:0	FEED	Feed value should be 0xAA followed by 0x55.	NA
31:8	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

# 15.8.4 Watchdog Timer Value register

The WDTV register is used to read the current value of Watchdog timer counter.

When reading the value of the 24 bit counter, the lock and synchronization procedure takes up to 6 WDCLK cycles plus 6 PCLK cycles, so the value of WDTV is older than the actual value of the timer when it's being read by the CPU.

Table 273. Watchdog Timer Value register (TV - 0x4000 400C) bit description

Bit	Symbol	Description	Reset Value
23:0	COUNT	Counter timer value.	0x00 00FF
31:24	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

# 15.8.5 Watchdog Clock Select register

Table 274. Watchdog Clock Select register (CLKSEL - 0x4000 4010) bit description

Bit	Symbol	Value	Description	Reset Value
0	CLKSEL		Selects source of WDT clock	0
		0	IRC	
		1	Watchdog oscillator (WDOSC)	
30:1	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
31	LOCK		If this bit is set to one writing to this register does not affect bit 0. The clock source can only be changed by first clearing this bit, then writing the new value of bit 0.	0

# 15.8.6 Watchdog Timer Warning Interrupt register

The WDWARNINT register determines the watchdog timer counter value that will generate a watchdog interrupt. When the watchdog timer counter matches the value defined by WDWARNINT, an interrupt will be generated after the subsequent WDCLK.

A match of the watchdog timer counter to WDWARNINT occurs when the bottom 10 bits of the counter have the same value as the 10 bits of WARNINT, and the remaining upper bits of the counter are all 0. This gives a maximum time of 1,023 watchdog timer counts (4,096 watchdog clocks) for the interrupt to occur prior to a watchdog event. If WARNINT is 0, the interrupt will occur at the same time as the watchdog event.

### Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

Table 275. Watchdog Timer Warning Interrupt register (WARNINT - 0x4000 4014) bit description

Bit	Symbol	Description	Reset Value
9:0	WARNINT	Watchdog warning interrupt compare value.	0
31:10	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

# 15.8.7 Watchdog Timer Window register

The WDWINDOW register determines the highest WDTV value allowed when a watchdog feed is performed. If a feed sequence occurs when WDTV is greater than the value in WDWINDOW, a watchdog event will occur.

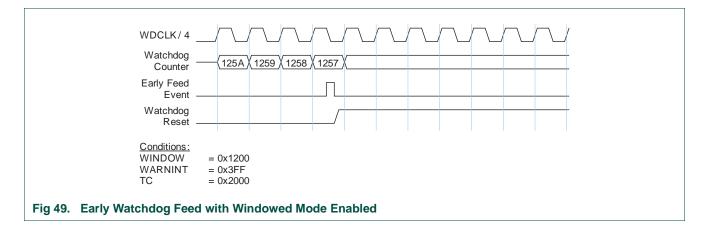

WDWINDOW resets to the maximum possible WDTV value, so windowing is not in effect.

Table 276. Watchdog Timer Window register (WINDOW - 0x4000 4018) bit description

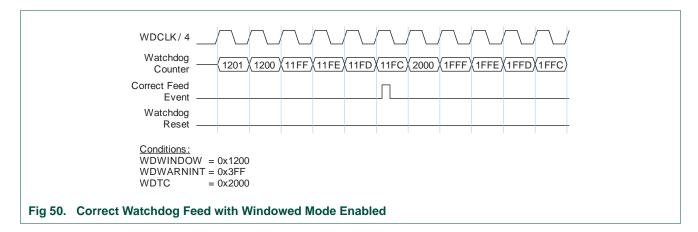

Bit	Symbol	Description	Reset Value
23:0	WINDOW	Watchdog window value.	0xFF FFFF
31:24	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

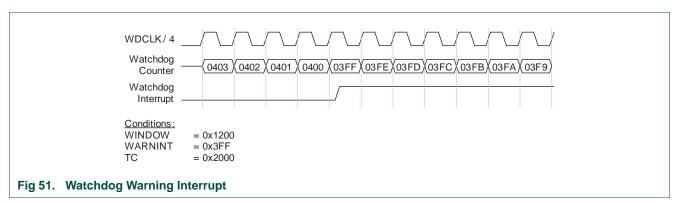

# 15.9 Watchdog timing examples

The following figures illustrate several aspects of Watchdog Timer operation.

# Chapter 15: LPC1315/16/17/45/46/47 Windowed Watchdog Timer

# **UM10462**

# Chapter 16: LPC1315/16/17/45/46/47 16-bit counter/timers CT16B0/1

Rev. 4 — 12 March 2013

**User manual** 

# 16.1 How to read this chapter

CT16B0/1 are available on all LPC1315/16/17/45/46/47 parts. The number of capture inputs depends on package size. See Chapter 8.

# 16.2 Basic configuration

The CT16B0/1 counter/timers are configured through the following registers:

- Pins: The CT16B0/1 pins must be configured in the IOCON register block.
- Power: In the SYSAHBCLKCTRL register, set bit 7 and 8 in Table 19.
- The peripheral clock is determined by the system clock (see Table 18).

**Remark:** The register offsets and bit offsets for capture channel 1 are different on timers CT16B0 and CT16B1. The affected registers are:

- Section 16.7.1 "Interrupt Register"
- Section 16.7.8 "Capture Control Register"
- Section 16.7.9 "Capture Registers"
- Section 16.7.11 "Count Control Register"

# 16.3 Features

- Two 16-bit counter/timers with a programmable 16-bit prescaler.
- Counter or timer operation
- Two 16-bit capture channels that can take a snapshot of the timer value when an input signal transitions. A capture event may also optionally generate an interrupt.
- The timer and prescaler may be configured to be cleared on a designated capture
  event. This feature permits easy pulse-width measurement by clearing the timer on
  the leading edge of an input pulse and capturing the timer value on the trailing edge.
- Four 16-bit match registers that allow:
  - Continuous operation with optional interrupt generation on match.
  - Stop timer on match with optional interrupt generation.
  - Reset timer on match with optional interrupt generation.
- Two external outputs corresponding to match registers with the following capabilities:
  - Set LOW on match.
  - Set HIGH on match.
  - Toggle on match.
  - Do nothing on match.

# Chapter 16: LPC1315/16/17/45/46/47 16-bit counter/timers CT16B0/1

 For each timer, up to four match registers can be configured as PWM allowing to use up to two match outputs as single edge controlled PWM outputs.

# 16.4 Applications

- Interval timer for counting internal events
- Pulse Width Demodulator via capture input
- Free running timer
- Pulse Width Modulator via match outputs

# 16.5 General description

Each Counter/timer is designed to count cycles of the peripheral clock (PCLK) or an externally supplied clock and can optionally generate interrupts or perform other actions at specified timer values based on four match registers. Each counter/timer also includes one capture input to trap the timer value when an input signal transitions, optionally generating an interrupt.

In PWM mode, up to three match registers (up to two match registers for CT16B1) can be used to provide a single-edge controlled PWM output on the match output pins. It is recommended to use the match registers that are not pinned out to control the PWM cycle length.

# 16.6 Pin description

Table 277 gives a brief summary of each of the counter/timer related pins.

Table 277. Counter/timer pin description

Pin	Туре	Description
CT16B0_CAP[1:0] CT16B1_CAP[1:0]	Input	Capture Signal: A transition on a capture pin can be configured to load the Capture Register with the value in the counter/timer and optionally generate an interrupt.
		The Counter/Timer block can select a capture signal as a clock source instead of the PCLK derived clock. For more details see Section 16.7.11.
CT16B0_MAT[2:0] CT16B1_MAT[1:0]	Output	External Match Outputs of CT16B0/1: When a match register of CT16B0/1 (MR1:0) equals the timer counter (TC), this output can either toggle, go LOW, go HIGH, or do nothing. The External Match Register (EMR) and the PWM Control Register (PWMCON) control the functionality of this output.

# 16.7 Register description

The 16-bit counter/timer0 contains the registers shown in <u>Table 278</u> and the 16-bit counter/timer1 contains the registers shown in <u>Table 279</u>. More detailed descriptions follow.

### Chapter 16: LPC1315/16/17/45/46/47 16-bit counter/timers CT16B0/1

[1] Reset value reflects the data stored in used bits only. It does not include reserved bits content.

# 16.7.1 Interrupt Register

The Interrupt Register consists of four bits for the match interrupts and two bits for the capture interrupts. If an interrupt is generated then the corresponding bit in the IR will be HIGH. Otherwise, the bit will be LOW. Writing a logic one to the corresponding IR bit will reset the interrupt. Writing a zero has no effect.

**Remark:** The bit positions for the CAP1 interrupts are different for counter/timer CT16B0 (CAP1 interrupt on bit 6, <u>Table 280</u>) and counter/timer CT16B1 (CAP1 interrupt on bit 5, <u>Table 281</u>).

Table 280. Interrupt Register (IR, address 0x4000 C000 (CT16B0)) bit description

Table 282. Timer Control Register (TCR, address 0x4000 C004 (CT16B0) and 0x4001 0004 (CT16B1)) bit description

Bit	Symbol	Value	Description	Reset value
1	CRST		Counter reset.	0
		0	Do nothing.	
		1	The Timer Counter and the Prescale Counter are synchronously reset on the next positive edge of PCLK. The counters remain reset until TCR[1] is returned to zero.	
31: 2	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

### 16.7.3 Timer Counter

The 16-bit Timer Counter is incremented when the Prescale Counter reaches its terminal count. Unless it is reset before reaching its upper limit, the TC will count up to the value 0x0000 FFFF and then wrap back to the value 0x0000 0000. This event does not cause an interrupt, but a Match register can be used to detect an overflow if needed.

Table 283: Timer counter registers (TC, address 0x4000 C008 (CT16B0) and 0x4001 0008 (CT16B1)) bit description

Bit	Symbol	Description	Reset value
15:0	TC	Timer counter value.	0

# 16.7.4 Prescale Register

The 16-bit Prescale Register specifies the maximum value for the Prescale Counter.

Table 284: Prescale registers (PR, address 0x4000 C00C (CT16B0) and 0x4001 000C (CT16B1)) bit description

Bit	Symbol	Description	Reset value
15:0	PCVAL	Prescale value.	0
31:16	-	Reserved.	-

# 16.7.5 Prescale Counter register

The 16-bit Prescale Counter controls division of PCLK by some constant value before it is applied to the Timer Counter. This allows control of the relationship between the resolution of the timer and the maximum time before the timer overflows. The Prescale Counter is incremented on every PCLK. When it reaches the value stored in the Prescale Register, the Timer Counter is incremented, and the Prescale Counter is reset on the next PCLK. This causes the TC to increment on every PCLK when PR = 0, every 2 PCLKs when PR = 1, ...

# 16.7.7 Match Registers

The Match register values are continuously compared to the Timer Counter value. When the two values are equal, actions can be triggered automatically. The action possibilities are to generate an interrupt, reset the Timer Counter, or stop the timer. Actions are controlled by the settings in the MCR register.

Table 287: Match registers (MR[0:3], addresses 0x4000 C018 (MR0) to 0x4000 C024 (MR3) (CT16B0) and 0x4001 0018 (MR0) to 0x4001 0024 (MR3) (CT16B1)) bit description

Bit	Symbol	Description	Reset value
15:0	MATCH	Timer counter match value.	0
31:16	-	Reserved.	-

# 16.7.8 Capture Control Register

The Capture Control Register is used to control whether the Capture Register is loaded with the value in the Counter/timer when the capture event occurs, and whether an interrupt is generated by the capture event. Setting both the rising and falling bits at the same time is a valid configuration, resulting in a capture event for both edges. In the description below, n represents the Timer number, 0 or 1.

Remark: The bit positions for the CAP1 channel control bits are different for counter/timers CT16B0 (bits 8:6, Table 288) and CT16B1 (bits 5:3, Table 289).

# 16.7.9 Capture Registers

Each Capture register is associated with a device pin and may be loaded with the counter/timer value when a specified event occurs on that pin. The settings in the Capture Control Register register determine whether the capture function is enabled, and whether a capture event happens on the rising edge of the associated pin, the falling edge, or on both edges.

**Remark:** The location of the CR1 register relative to the timer base address is different for CT16B0 (CR1 at +0x034, <u>Table 291</u>) and CT16B1 (CR1 at +0x030, <u>Table 292</u>).

Table 290: Capture register 0 (CR0, address 0x4000 C02C (CT16B0) and address 0x4001 002C (CT16B1)) bit description

# 16.7.10 External Match Register

The External Match Register provides both control and status of the external match pins CT16Bn\_MAT[1:0].

If the match outputs are configured as PWM output, the function of the external match registers is determined by the PWM rules (<u>Section 16.7.13 "Rules for single edge</u> controlled PWM outputs" on page 325).

Table 293. External Match Register (EMR, address 0x4000 C03C (CT16B0) and 0x4001 003C (CT16B1)) bit description

	description				
Bit	Symbol	Value	Description	Reset value	
0	ЕМО		External Match 0. This bit reflects the state of output CT16B0_MAT0/CT16B1_MAT0, whether or not this output is connected to its pin. When a match occurs between the TC and MR0, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[5:4] control the functionality of this output. This bit is driven to the CT16B0_MAT0/CT16B1_MAT0 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0	
1	EM1		External Match 1. This bit reflects the state of output CT16B0_MAT1/CT16B1_MAT1, whether or not this output is connected to its pin. When a match occurs between the TC and MR1, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[7:6] control the functionality of this output. This bit is driven to the CT16B0_MAT0/CT16B1_MAT0 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0	
2	EM2		External Match 2. This bit reflects the state of match channel 2. When a match occurs between the TC and MR2, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[9:8] control the functionality of this output.	0	
3	EM3		External Match 3. This bit reflects the state of output of match channel 3. When a match occurs between the TC and MR3, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[11:10] control the functionality of this output.	0	
5:4	EMC0		External Match Control 0. Determines the functionality of External Match 0. <u>Table 294</u> shows the encoding of these bits.	00	
		0x0	Do Nothing.		
		0x1	Clear the corresponding External Match bit/output to 0 (CT16Bn_MAT0 pin is LOW if pinned out).		
		0x2	Set the corresponding External Match bit/output to 1 (CT16Bn_MAT0 pin is HIGH if pinned out).		
		0x3	Toggle the corresponding External Match bit/output.

00	Do Nothing.
01	Clear the corresponding External Match bit/output to 0 (CT16Bn_MATm pin is LOW if pinned out).
10	Set the corresponding External Match bit/output to 1 (CT16Bn_MATm pin is HIGH if pinned out).
11	Toggle the corresponding External Match bit/output.

# 16.7.11 Count Control Register

The Count Control Register (CTCR) is used to select between Timer and Counter mode, and in Counter mode to select the pin and edges for counting.

When Counter Mode is chosen as a mode of operation, the CAP input (selected by the CTCR bits 3:2) is sampled on every rising edge of the PCLK clock. After comparing two consecutive samples of this CAP input, one of the following four events is recognized: rising edge, falling edge, either of edges or no changes in the level of the selected CAP input. Only if the identified event occurs, and the event corresponds to the one selected by bits 1:0 in the CTCR register, will the Timer Counter register be incremented.

# Chapter 16: LPC1315/16/17/45/46/47 16-bit counter/timers CT16B0/1

Effective processing of the externally supplied clock to the counter has some limitations. Since two successive rising edges of the PCLK clock are used to identify only one edge on the CAP selected input, the frequency of the CAP input cannot exceed one half of the PCLK clock. Consequently, the duration of the HIGH/LOW levels on the same CAP input in this case can not be shorter than 1/PCLK.

Bits 7:4 of this register are also used to enable and configure the capture-clears-timer feature. This feature allows for a designated edge on a particular CAP input to reset the timer to all zeros. Using this mechanism to clear the timer on the leading edge of an input pulse and performing a capture on the trailing edge, permits direct pulse-width measurement using a single capture input without the need to perform a subtraction operation in software.

**Remark:** The bit positions for the CAP1 channel count input select (CIS) and edge select bits (SELCC) are different for counter/timers CT16B0 (<u>Table 295</u>) and CT16B1 (<u>Table 296</u>).

Table 295. Count Control Register (CTCR, address 0x4000 C070 (CT16B0)) bit description

Bit	Symbol	Value	Description	Reset value
1:0	СТМ		Counter/Timer Mode. This field selects which rising PCLK edges can increment Timer's Prescale Counter (PC), or clear PC and increment Timer Counter (TC).	0

# 16.7.12 PWM Control register

The PWM Control Register is used to configure the match outputs as PWM outputs. Each match output can be independently set to perform either as PWM output or as match output whose function is controlled by the External Match Register (EMR).

For each timer, a maximum of three single edge controlled PWM outputs can be selected on the CT16Bn\_MAT[1:0] outputs. One additional match register determines the PWM cycle length. When a match occurs in any of the other match registers, the PWM output is set to HIGH. The timer is reset by the match register that is configured to set the PWM cycle length. When the timer is reset to zero, all currently HIGH match outputs configured as PWM outputs are cleared.

Table 297. PWM Control Register (PWMC, address 0x4000 C074 (CT16B0) and 0x4001 0074 (CT16B1)) bit description

Bit	Symbol	Value	Description	Reset value

31:4	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-

#### 16.7.13 Rules for single edge controlled PWM outputs

- 1. All single edge controlled PWM outputs go LOW at the beginning of each PWM cycle (timer is set to zero) unless their match value is equal to zero.
- Each PWM output will go HIGH when its match value is reached. If no match occurs (i.e. the match value is greater than the PWM cycle length), the PWM output remains continuously LOW.
- If a match value larger than the PWM cycle length is written to the match register, and the PWM signal is HIGH already, then the PWM signal will be cleared on the next start of the next PWM cycle.
- 4. If a match register contains the same value as the timer reset value (the PWM cycle length), then the PWM output will be reset to LOW on the next clock tick. Therefore, the PWM output will always consist of a one clock tick wide positive pulse with a period determined by the PWM cycle length (i.e. the timer reload value).
- 5. If a match register is set to zero, then the PWM output will go to HIGH the first time the timer goes back to zero and will stay HIGH continuously.

**Note:** When the match outputs are selected to perform as PWM outputs, the timer reset (MRnR) and timer stop (MRnS) bits in the Match Control Register MCR must be set to zero except for the match register setting the PWM cycle length. For this register, set the MRnR bit to one to enable the timer reset when the timer value matches the value of the corresponding match register.

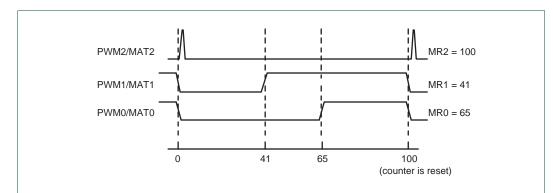

Fig 52. Sample PWM waveforms with a PWM cycle length of 100 (selected by MR2) and MAT1:0 enabled as PWM outputs by the PWMC register.

#### Chapter 16: LPC1315/16/17/45/46/47 16-bit counter/timers CT16B0/1

### 16.8 Example timer operation

Figure 53 shows a timer configured to reset the count and generate an interrupt on match. The prescaler is set to 2 and the match register set to 6. At the end of the timer cycle where the match occurs, the timer count is reset. This gives a full length cycle to the match value. The interrupt indicating that a match occurred is generated in the next clock after the timer reached the match value.

Figure 54 shows a timer configured to stop and generate an interrupt on match. The prescaler is again set to 2 and the match register set to 6. In the next clock after the timer reaches the match value, the timer enable bit in TCR is cleared, and the interrupt indicating that a match occurred is generated.

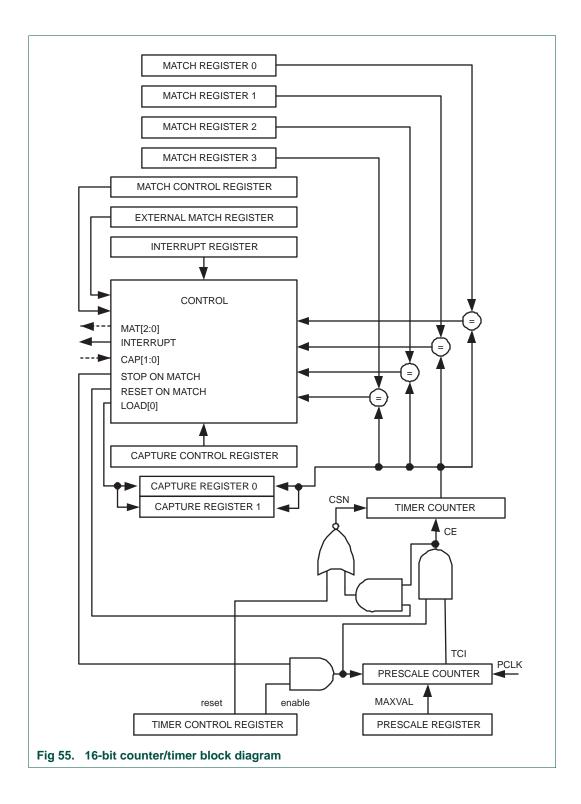

#### 16.9 Architecture

The block diagram for counter/timer0 and counter/timer1 is shown in Figure 55.

Rev. 4 — 12 March 2013

**User manual** 

### 17.1 How to read this chapter

CT32B0/1 are available on all LPC1315/16/17/45/46/47 parts. The CT32B1\_CAP1 input is only available on the TFBGA48 and LQFP64 packages. The CT32B0\_CAP1 input is only available on LQFP48, TFBGA48, and LQFP64 packages. For all other packages, the registers controlling the CT32B1\_CAP1 and CT32B0\_CAP1 inputs are reserved.

### 17.2 Basic configuration

The CT32B0/1 counter/timers are configured through the following registers:

- Pins: The CT32B0/1 pins must be configured in the IOCON register block.
- Power: In the SYSAHBCLKCTRL register, set bit 9 and 10 in <u>Table 19</u>.
- The peripheral clock is determined by the system clock (see <u>Table 18</u>).

**Remark:** The register offsets and bit offsets for capture channel 1 are different on timers CT32B0 and CT32B1. The affected registers are:

- Section 17.7.1 "Interrupt Register"
- Section 17.7.8 "Capture Control Register"
- Section 17.7.9 "Capture Registers"
- Section 17.7.11 "Count Control Register"

#### 17.3 Features

- Two 32-bit counter/timers with a programmable 32-bit prescaler.
- Counter or timer operation.
- Four 32-bit capture channels that can take a snapshot of the timer value when an input signal transitions. A capture event may also optionally generate an interrupt.
- The timer and prescaler may be configured to be cleared on a designated capture event. This feature permits easy pulse-width measurement by clearing the timer on the leading edge of an input pulse and capturing the timer value on the trailing edge.
- Four 32-bit match registers that allow:
  - Continuous operation with optional interrupt generation on match.
  - Stop timer on match with optional interrupt generation.
  - Reset timer on match with optional interrupt generation.
- Four external outputs corresponding to match registers with the following capabilities:
  - Set LOW on match.
  - Set HIGH on match.
  - Toggle on match.

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

- Do nothing on match.
- For each timer, up to four match registers can be configured as PWM allowing to use up to three match outputs as single edge controlled PWM outputs.

### 17.4 Applications

- Interval timer for counting internal events
- Pulse Width Demodulator via capture input
- · Free running timer
- Pulse Width Modulator via match outputs

### 17.5 General description

Each Counter/timer is designed to count cycles of the peripheral clock (PCLK) or an externally supplied clock and can optionally generate interrupts or perform other actions at specified timer values based on four match registers. Each counter/timer also includes one capture input to trap the timer value when an input signal transitions, optionally generating an interrupt.

In PWM mode, three match registers can be used to provide a single-edge controlled PWM output on the match output pins. One match register is used to control the PWM cycle length.

### 17.6 Pin description

Table 298 gives a brief summary of each of the counter/timer related pins.

Table 298. Counter/timer pin description

Pin	Туре	Description
CT32B0_CAP[1:0] CT32B1_CAP[1:0]	Input	Capture Signals: A transition on a capture pin can be configured to load one of the Capture Registers with the value in the Timer Counter and optionally generate an interrupt.
		The counter/timer block can select a capture signal as a clock source instead of the PCLK derived clock. For more details see Section 17.7.11 "Count Control Register" on page 339.
CT32B0_MAT[3:0] CT32B1_MAT[3:0]	Output	External Match Output of CT32B0/1: When a match register MR3:0 equals the timer counter (TC), this output can either toggle, go LOW, go HIGH, or do nothing. The External Match Register (EMR) and the PWM Control register (PWMCON) control the functionality of this output.

### 17.7 Register description

32-bit counter/timer0 contains the registers shown in <u>Table 299</u> and 32-bit counter/timer1 contains the registers shown in <u>Table 300</u>. More detailed descriptions follow.

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

#### 17.7.1 Interrupt Register

The Interrupt Register consists of four bits for the match interrupts and four bits for the capture interrupts. If an interrupt is generated then the corresponding bit in the IR will be HIGH. Otherwise, the bit will be LOW. Writing a logic one to the corresponding IR bit will reset the interrupt. Writing a zero has no effect.

**Remark:** The bit positions for the CAP1 interrupts are different for counter/timer CT32B0 (CAP1 interrupt on bit 6, <u>Table 301</u>) and counter/timer CT32B1 (CAP1 interrupt on bit 5, <u>Table 302</u>).

Table 301: Interrupt Register (IR, address 0x4001 4000 (CT32B0)) bit description

Bit	Symbol	Description	Reset value
0	MR0INT	Interrupt flag for match channel 0.	0
1	MR1INT	Interrupt flag for match channel 1.	0

5	CR1INT	Interrupt flag for capture channel 1 event.	0
31:6	-	Reserved	-

### 17.7.2 Timer Control Register

The Timer Control Register (TCR) is used to control the operation of the counter/timer.

Table 303: Timer Control Register (TCR, address 0x4001 4004 (CT32B0) and 0x4001 8004 (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value	
0	CEN	CEN 0		Counter enable.	0
			0 The counters are disabled.	The counters are disabled.	
		1	The Timer Counter and Prescale Counter are enabled for counting.		

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

Table 303: Timer Control Register (TCR, address 0x4001 4004 (CT32B0) and 0x4001 8004 (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value
1	CRST		Counter reset.	0
		0	Do nothing.	
		1	The Timer Counter and the Prescale Counter are synchronously reset on the next positive edge of PCLK. The counters remain reset until TCR[1] is returned to zero.	
31:2	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 17.7.3 Timer Counter registers

The 32-bit Timer Counter is incremented when the Prescale Counter reaches its terminal count. Unless it is reset before reaching its upper limit, the TC will count up through the value 0xFFFF FFFF and then wrap back to the value 0x0000 0000. This event does not cause an interrupt, but a Match register can be used to detect an overflow if needed.

Table 304: Timer counter registers (TC, address 0x4001 4008 (CT32B0) and 0x4001 8008 (CT32B1)) bit description

Bit	Symbol	Description	Reset value
31:0	TC	Timer counter value.	0

#### 17.7.4 Prescale Register

The 32-bit Prescale Register specifies the maximum value for the Prescale Counter.

Table 305: Prescale registers (PR, address 0x4001 400C (CT32B0) and 0x4001 800C (CT32B1)) bit description

Bit	Symbol	Description	Reset value
31:0	PCVAL	Prescaler value.	0

#### 17.7.5 Prescale Counter Register

The 32-bit Prescale Counter controls division of PCLK by some constant value before it is applied to the Timer Counter. This allows control of the relationship between the resolution of the timer and the maximum time before the timer overflows. The Prescale Counter is incremented on every PCLK. When it reaches the value stored in the Prescale Register, the Timer Counter is incremented, and the Prescale Counter is reset on the next PCLK. This causes the TC to increment on every PCLK when PR = 0, every 2 PCLKs when PR = 1, etc.

Table 306: Prescale registers (PC, address 0x4001 4010 (CT32B0) and 0x4001 8010 (CT32B1)) bit description

Bit	Symbol	Description	Reset value
31:0	PC	Prescale counter value.	0

#### 17.7.6 Match Control Register

The Match Control Register is used to control what operations are performed when one of the Match Registers matches the Timer Counter. The function of each of the bits is shown in Table 307.

Table 307: Match Control Register (MCR, address 0x4001 4014 (CT32B0) and 0x4001 8014 (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value
0	MR0I		Interrupt on MR0: an interrupt is generated when MR0 matches the value in the TC.	0
		1	Enabled	
		0	Disabled	
1	MR0R		Reset on MR0: the TC will be reset if MR0 matches it.	0
		1	Enabled	
		0	Disabled	
2	MR0S		Stop on MR0: the TC and PC will be stopped and TCR[0] will be set to 0 if MR0 matches the TC.	0
		1	Enabled	
		0	Disabled	
3	MR1I		Interrupt on MR1: an interrupt is generated when MR1 matches the value in the TC.	0
		1	Enabled	
		0	Disabled	
4	MR1R		Reset on MR1: the TC will be reset if MR1 matches it.	0
		1	Enabled	
		0	Disabled	
5	MR1S		Stop on MR1: the TC and PC will be stopped and TCR[0] will be set to 0 if MR1 matches the TC.	0
		1	Enabled	
		0	Disabled	
6	MR2I		Interrupt on MR2: an interrupt is generated when MR2 matches the value in the TC.	0
		1	Enabled	
		0	Disabled	
7	MR2R		Reset on MR2: the TC will be reset if MR2 matches it.	0
		1	Enabled	
		0	Disabled	
8	MR2S		Stop on MR2: the TC and PC will be stopped and TCR[0] will be set to 0 if MR2 matches the TC.	0
		1	Enabled	
		0	Disabled	
9	MR3I		Interrupt on MR3: an interrupt is generated when MR3 matches the value in the TC.	0
		1	Enabled	
		0	Disabled	
10	MR3R		Reset on MR3: the TC will be reset if MR3 matches it.	0
		1	Enabled	
		0	Disabled	

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

Table 307: Match Control Register (MCR, address 0x4001 4014 (CT32B0) and 0x4001 8014 (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value
11	MR3S		Stop on MR3: the TC and PC will be stopped and TCR[0] will be set to 0 if MR3 matches the TC.	0
		1	Enabled	
		0	Disabled	
31:12	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 17.7.7 Match Registers

The Match register values are continuously compared to the Timer Counter value. When the two values are equal, actions can be triggered automatically. The action possibilities are to generate an interrupt, reset the Timer Counter, or stop the timer. Actions are controlled by the settings in the MCR register.

Table 308: Match registers (MR[0:3], addresses 0x4001 4018 (MR0) to 0x4001 4024 (MR3) (CT32B0) and 0x4001 8018 (MR0) to 0x40018024 (MR3) (CT32B1)) bit description

Bit	Symbol	Description	Reset value
31:0	MATCH	Timer counter match value.	0

#### 17.7.8 Capture Control Register

The Capture Control Register is used to control whether one of the four Capture Registers is loaded with the value in the Timer Counter when the capture event occurs, and whether an interrupt is generated by the capture event. Setting both the rising and falling bits at the same time is a valid configuration, resulting in a capture event for both edges. In the description below, "n" represents the Timer number, 0 or 1.

**Remark:** The bit positions for the CAP1 channel control bits are different for counter/timers CT32B0 (bits 8:6, Table 309) and CT32B1 (bits 5:3, Table 310).

Table 309: Capture Control Register (CCR, address 0x4001 4028 (CT32B0)) bit description

Bit	Symbol	Value	Description	Reset value
0	CAP0RE		Capture on CT32B0_CAP0 rising edge: a sequence of 0 then 1 on CT32B0_CAP0 will cause CR0 to be loaded with the contents of TC.	0
		1	Enabled.	
		0	Disabled.	
1	CAP0FE		Capture on CT32B0_CAP0 falling edge: a sequence of 1 then 0 on CT32B0_CAP0 will cause CR0 to be loaded with the contents of TC.	0
		1	Enabled.	
		0	Disabled.	
2	CAP0I		Interrupt on CT32B0_CAP0 event: a CR0 load due to a CT32B0_CAP0 event will generate an interrupt.	0
		1	Enabled.	
		0	Disabled.	
5:3	-		Reserved.	-

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

		1	Enabled.	
		0	Disabled.	
31:6	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 17.7.9 Capture Registers

Each Capture register is associated with a device pin and may be loaded with the Timer Counter value when a specified event occurs on that pin. The settings in the Capture Control Register register determine whether the capture function is enabled, and whether a capture event happens on the rising edge of the associated pin, the falling edge, or on both edges.

**Remark:** The location of the CR1 register relative to the timer base address is different for CT32B0 (CR1 at +0x034, Table 312) and CT32B1 (CR1 at +0x030, Table 302).

Table 311: Capture registers (CR0, addresses 0x4001 402C (CT32B0) and 0x4001 802C (CT32B1)) bit description

Bit	Symbol	Description	Reset value

### 17.7.10 External Match Register

The External Match Register provides both control and status of the external match pins CAP32Bn\_MAT[3:0].

If the match outputs are configured as PWM output, the function of the external match registers is determined by the PWM rules (<u>Section 17.7.13 "Rules for single edge controlled PWM outputs" on page 342</u>).

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

Table 314: External Match Register (EMR, address 0x4001 403C (CT32B0) and 0x4001 803C (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value
0	EM0		External Match 0. This bit reflects the state of output CT32Bn_MAT0, whether or not this output is connected to its pin. When a match occurs between the TC and MR0, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[5:4] control the functionality of this output. This bit is driven to the CT32B0_MAT0/CT32B1_MAT0 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0
1	EM1		External Match 1. This bit reflects the state of output CT32Bn_MAT1, whether or not this output is connected to its pin. When a match occurs between the TC and MR1, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[7:6] control the functionality of this output. This bit is driven to the CT32B0_MAT1/CT32B1_MAT1 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0
2	EM2		External Match 2. This bit reflects the state of output CT32Bn_MAT2, whether or not this output is connected to its pin. When a match occurs between the TC and MR2, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[9:8] control the functionality of this output. This bit is driven to the CT32B0_MAT2/CT32B1_MAT2 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0
3	EM3		External Match 3. This bit reflects the state of output CT32Bn_MAT3, whether or not this output is connected to its pin. When a match occurs between the TC and MR3, this bit can either toggle, go LOW, go HIGH, or do nothing. Bits EMR[11:10] control the functionality of this output. This bit is driven to the CT32B3_MAT0/CT32B1_MAT3 pins if the match function is selected in the IOCON registers (0 = LOW, 1 = HIGH).	0
5:4	EMC0		External Match Control 0. Determines the functionality of External Match 0.	00
		0x0	Do Nothing.	
		0x1	Clear the corresponding External Match bit/output to 0 (CT32Bi_MAT0 pin is LOW if pinned out).	
		0x2	Set the corresponding External Match bit/output to 1 (CT32Bi_MAT0 pin is HIGH if pinned out).	
		0x3	Toggle the corresponding External Match bit/output.	
7:6	EMC1		External Match Control 1. Determines the functionality of External Match 1.	00
		0x0	Do Nothing.	
		0x1	Clear the corresponding External Match bit/output to 0 (CT32Bi_MAT1 pin is LOW if pinned out).	
		0x2	Set the corresponding External Match bit/output to 1 (CT32Bi_MAT1 pin is HIGH if pinned out).	
		0x3	Toggle the corresponding External Match bit/output.	
9:8	EMC2		External Match Control 2. Determines the functionality of External Match 2.	00
		0x0	Do Nothing.	
		0x1	Clear the corresponding External Match bit/output to 0 (CT32Bi_MAT2 pin is LOW if pinned out).	
		0x2	Set the corresponding External Match bit/output to 1 (CT32Bi_MAT2 pin is HIGH if pinned out).	
		0x3	Toggle the corresponding External Match bit/output.

Bit	Symbol	Value	Description	Reset value
11:10	EMC3		External Match Control 3. Determines the functionality of External Match 3.	00
		0x0	Do Nothing.	
		0x1	Clear the corresponding External Match bit/output to 0 (CT32Bi_MAT3 pin is LOW if pinned out).	
		0x2	Set the corresponding External Match bit/output to 1 (CT32Bi_MAT3 pin is HIGH if pinned out).	
		0x3	Toggle the corresponding External Match bit/output.	
31:12	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### Table 315. External match control

EMR[11:10], EMR[9:8], EMR[7:6], or EMR[5:4]	Function
00	Do Nothing.
01	Clear the corresponding External Match bit/output to 0 (CT32Bn_MATm pin is LOW if pinned out).
10	Set the corresponding External Match bit/output to 1 (CT32Bn_MATm pin is HIGH if pinned out).
11	Toggle the corresponding External Match bit/output.

#### 17.7.11 Count Control Register

The Count Control Register (CTCR) is used to select between Timer and Counter mode, and in Counter mode to select the pin and edges for counting.

When Counter Mode is chosen as a mode of operation, the CAP input (selected by the CTCR bits 3:2) is sampled on every rising edge of the PCLK clock. After comparing two consecutive samples of this CAP input, one of the following four events is recognized: rising edge, falling edge, either of edges or no changes in the level of the selected CAP input. Only if the identified event occurs, and the event corresponds to the one selected by bits 1:0 in the CTCR register, will the Timer Counter register be incremented.

Effective processing of the externally supplied clock to the counter has some limitations. Since two successive rising edges of the PCLK clock are used to identify only one edge on the CAP selected input, the frequency of the CAP input cannot exceed one half of the PCLK clock. Consequently, duration of the HIGH/LOW levels on the same CAP input in this case cannot be shorter than 1/PCLK.

Bits 7:4 of this register are also used to enable and configure the capture-clears-timer feature. This feature allows for a designated edge on a particular CAP input to reset the timer to all zeros. Using this mechanism to clear the timer on the leading edge of an input pulse and performing a capture on the trailing edge, permits direct pulse-width measurement using a single capture input without the need to perform a subtraction operation in software.

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

**Remark:** The bit positions for the CAP1 channel count input select (CIS) and edge select bits (SELCC) are different for counter/timers CT16B0 (<u>Table 316</u>) and CT16B1 (<u>Table 317</u>).

Table 316: Count Control Register (CTCR, address 0x4001 4070 (CT32B0)) bit description

Bit	Symbol	Value	Description	Reset value
1:0	СТМ		Counter/Timer Mode. This field selects which rising PCLK edges can increment Timer's Prescale Counter (PC), or clear PC and increment Timer Counter (TC).	00
			<b>Remark:</b> If Counter mode is selected in the CTCR, bits 2:0 in the Capture Control Register (CCR) must be programmed as 000.	
		0x0	Timer Mode: every rising PCLK edge	
		0x1	Counter Mode: TC is incremented on rising edges on the CAP input selected by bits 3:2.	
		0x2	Counter Mode: TC is incremented on falling edges on the CAP input selected by bits 3:2.	<b>)</b>
		0x3	Counter Mode: TC is incremented on both edges on the CAP input selected by bits 3:2.	
3:2	CIS		Count Input Select. In counter mode (when bits 1:0 in this register are not 00), these bits select which CAP pin or comparator output is sampled for clocking.	00
			<b>Remark:</b> If Counter mode is selected in the CTCR, the 3 bits for that input in the Capture Control Register (CCR) must be programmed as 000. Values 0x1 and 0x3 are reserved.	
		0x0	CT32B0_CAP0

		0x3	Falling Edge of CT32B1_CAP1 clears the timer (if bit 4 is set)	
31:8	-	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-

#### 17.7.12 PWM Control Register

The PWM Control Register is used to configure the match outputs as PWM outputs. Each match output can be independently set to perform either as PWM output or as match output whose function is controlled by the External Match Register (EMR).

For each timer, a maximum of three single edge controlled PWM outputs can be selected on the MATn.2:0 outputs. One additional match register determines the PWM cycle length. When a match occurs in any of the other match registers, the PWM output is set to

UM10462 **NXP Semiconductors** 

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

HIGH. The timer is reset by the match register that is configured to set the PWM cycle length. When the timer is reset to zero, all currently HIGH match outputs configured as PWM outputs are cleared.

Table 318: PWM Control Register (PWMC, 0x4001 4074 (CT32B0) and 0x4001 8074 (CT32B1)) bit description

Bit	Symbol	Value	Description	Reset value
0	PWMEN0		PWM mode enable for channel0.	0
		0	CT32Bn_MAT0 is controlled by EM0.	
		1	PWM mode is enabled for CT32Bn_MAT0.

	0	0	CT32Bn_MAT01 is controlled by EM1.	
		1	PWM mode is enabled for CT32Bn_MAT1.	
2	2 PWMEN2		PWM mode enable for channel2.	0
		0	CT32Bn_MAT2 is controlled by EM2.	
		1	PWM mode is enabled for CT32Bn_MAT2.	
3	3 PWMEN3		PWM mode enable for channel3. <b>Note:</b> It is recommended to use match channel 3 to set the PWM cycle.	0
		0	CT32Bn_MAT3 is controlled by EM3.	
		1	PWM mode is enabled for CT132Bn_MAT3.	
31:4	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 17.7.13 Rules for single edge controlled PWM outputs

- 1. All single edge controlled PWM outputs go LOW at the beginning of each PWM cycle (timer is set to zero) unless their match value is equal to zero.
- 2. Each PWM output will go HIGH when its match value is reached. If no match occurs (i.e. the match value is greater than the PWM cycle length), the PWM output remains continuously LOW.
- 3. If a match value larger than the PWM cycle length is written to the match register, and the PWM signal is HIGH already, then the PWM signal will be cleared with the start of the next PWM cycle.
- 4. If a match register contains the same value as the timer reset value (the PWM cycle length), then the PWM output will be reset to LOW on the next clock tick after the timer reaches the match value. Therefore, the PWM output will always consist of a one clock tick wide positive pulse with a period determined by the PWM cycle length (i.e. the timer reload value).
- 5. If a match register is set to zero, then the PWM output will go to HIGH the first time the timer goes back to zero and will stay HIGH continuously.

#### Chapter 17: LPC1315/16/17/45/46/47 32-bit counter/timers CT32B0/1

**Note:** When the match outputs are selected to perform as PWM outputs, the timer reset (MRnR) and timer stop (MRnS) bits in the Match Control Register MCR must be set to zero except for the match register setting the PWM cycle length. For this register, set the MRnR bit to one to enable the timer reset when the timer value matches the value of the corresponding match register.

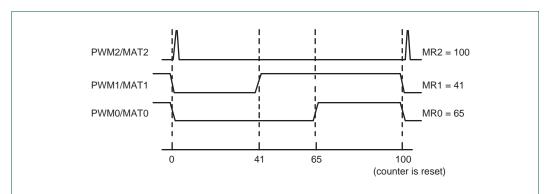

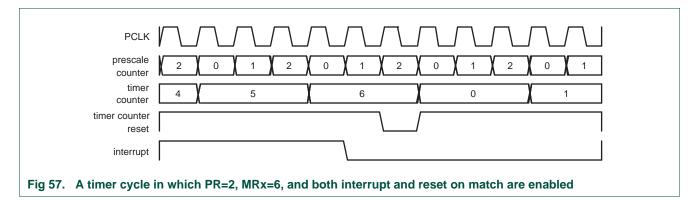

Fig 56. Sample PWM waveforms with a PWM cycle length of 100 (selected by MR2) and MAT1:0 enabled as PWM outputs by the PWMC register.

### 17.8 Example timer operation

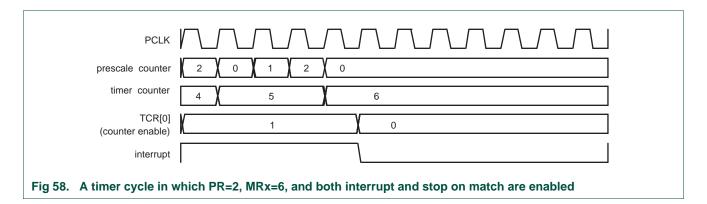

<u>Figure 57</u> shows a timer configured to reset the count and generate an interrupt on match. The prescaler is set to 2 and the match register set to 6. At the end of the timer cycle where the match occurs, the timer count is reset. This gives a full length cycle to the match value. The interrupt indicating that a match occurred is generated in the next clock after the timer reached the match value.

<u>Figure 58</u> shows a timer configured to stop and generate an interrupt on match. The prescaler is again set to 2 and the match register set to 6. In the next clock after the timer reaches the match value, the timer enable bit in TCR is cleared, and the interrupt indicating that a match occurred is generated.

## **UM10524**

### Chapter 18: LPC1315/16/17/45/46/47 System tick timer

Rev. 4 — 12 March 2013

**User manual** 

### 18.1 How to read this chapter

The system tick timer (SysTick timer) is part of the ARM Cortex-M3 core and is identical for all LPC1315/16/17/45/46/47 parts.

### 18.2 Basic configuration

The system tick timer is configured using the following registers:

- 1. Pins: The system tick timer uses no external pins.
- Power: The system tick timer is enabled through the SysTick control register in the ARM Cortex-M3. The system tick timer clock is fixed to half the frequency of the system clock.
- 3. Enable the clock source for the SysTick timer in the SYST\_CSR register.

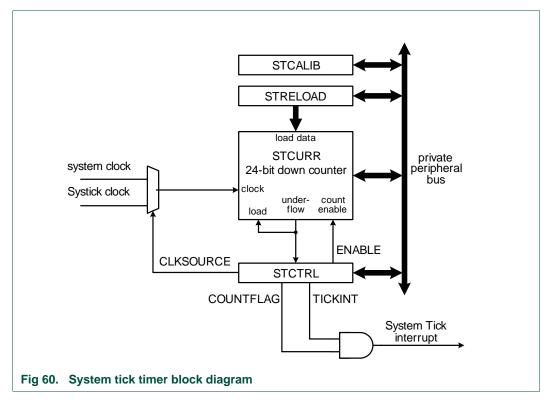

#### 18.3 Features

- Simple 24-bit timer.
- Uses dedicated exception vector.
- Clocked internally by the system clock or the SYSTICKCLK.

### 18.4 General description

The block diagram of the SysTick timer is shown below in the Figure 60.

#### Chapter 18: LPC1315/16/17/45/46/47 System tick timer

The SysTick timer is an integral part of the Cortex-M3. The SysTick timer is intended to generate a fixed 10 millisecond interrupt for use by an operating system or other system management software.

Since the SysTick timer is a part of the Cortex-M3, it facilitates porting of software by providing a standard timer that is available on Cortex-M3 based devices. The SysTick timer can be used for:

- An RTOS tick timer which fires at a programmable rate (for example 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the core clock.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

Refer to the Cortex-M3 User Guide for details.

### 18.5 Register description

The systick timer registers are located on the ARM Cortex-M3 private peripheral bus (see Figure 2), and are part of the ARM Cortex-M3 core peripherals. For details, see Section 21.5.4.

#### Chapter 18: LPC1315/16/17/45/46/47 System tick timer

Table 319. Register overview: SysTick timer (base address 0xE000 E000)

Name	Access	Address offset	Description	Reset value[1]	Reference

SYST_RVR	R/W	0x014	System Timer Reload value register	0	<u>Table 321</u>
SYST_CVR	R/W	0x018	System Timer Current value register	0	Table 322
SYST_CALIB	R/W	0x01C	System Timer Calibration value register	0x4	Table 323

<sup>[1]</sup> Reset Value reflects the data stored in used bits only. It does not include content of reserved bits.

#### 18.5.1 System Timer Control and status register

The SYST\_CSR register contains control information for the SysTick timer and provides a status flag. This register is part of the ARM Cortex-M3 core system timer register block. For a bit description of this register, see Section 21.5.4.

This register determines the clock source for the system tick timer.

Table 320. SysTick Timer Control and status register (SYST\_CSR - 0xE000 E010) bit description

Bit	Symbol	Description	Reset value
0	ENABLE	System Tick counter enable. When 1, the counter is enabled. When 0, the counter is disabled.	0
1	TICKINT	System Tick interrupt enable. When 1, the System Tick interrupt is enabled. When 0, the System Tick interrupt is disabled. When enabled, the interrupt is generated when the System Tick counter counts down to 0.	0
2	CLKSOURCE	System Tick clock source selection. When 1, the system clock (CPU) clock is selected. When 0, the output clock from the system tick clock divider (SYSTICKDIV) is selected as the reference clock. In this case, the core clock must be at least 2.5 times faster than the reference clock otherwise the count values are unpredictable.	0
15:3	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
16	COUNTFLAG	Returns 1 if the SysTick timer counted to 0 since the last read of this register.	0
31:17	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 18.5.2 System Timer Reload value register

The SYST\_RVR register is set to the value that will be loaded into the SysTick timer whenever it counts down to zero. This register is loaded by software as part of timer initialization. The SYST\_CALIB register may be read and used as the value for SYST\_RVR register if the CPU is running at the frequency intended for use with the SYST\_CALIB value.

#### Chapter 18: LPC1315/16/17/45/46/47 System tick timer

Table 321. System Timer Reload value register (SYST\_RVR - 0xE000 E014) bit description

Bit	Symbol	Description	Reset value
23:0	RELOAD	This is the value that is loaded into the System Tick counter when it counts down to $0. \\$	0
31:24	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 18.5.3 System Timer Current value register

The SYST\_CVR register returns the current count from the System Tick counter when it is read by software.

Table 322. System Timer Current value register (SYST\_CVR - 0xE000 E018) bit description

Bit	Symbol	Description	Reset value
23:0	CURRENT	Reading this register returns the current value of the System Tick counter. Writing any value clears the System Tick counter and the COUNTFLAG bit in STCTRL.	0
31:24	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 18.5.4 System Timer Calibration value register (SYST\_CALIB - 0xE000 E01C)

The value of the SYST\_CALIB register is driven by the value of the SYSTCKCAL register in the system configuration block (see <u>Table 24</u>).

Table 323. System Timer Calibration value register (SYST\_CALIB - 0xE000 E01C) bit description

Bit	Symbol	Value	Description	Reset value
23:0	TENMS		See <u>Table 367</u> .	0x4
29:24	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
30	SKEW		See <u>Table 367</u> .	0
31	NOREF		See <u>Table 367</u> .	0

### 18.6 Functional description

The SysTick timer is a 24-bit timer that counts down to zero and generates an interrupt. The intent is to provide a fixed 10 millisecond time interval between interrupts. The SysTick timer is clocked from the CPU clock (the system clock, see <a href="Figure 2">Figure 2</a>) or from the reference clock, which is fixed to half the frequency of the CPU clock. In order to generate recurring interrupts at a specific interval, the SYST\_RVR register must be initialized with the correct value for the desired interval. A default value is provided in the SYST\_CALIB register and may be changed by software. The default value gives a 10 millisecond interrupt rate if the CPU clock is set to 50 MHz.

#### Chapter 18: LPC1315/16/17/45/46/47 System tick timer

### 18.7 Example timer calculations

To use the system tick timer, do the following:

- Program the LOAD register with the reload value RELOAD to obtain the desired time interval.
- 2. Clear the VAL register by writing to it. This ensures that the timer will count from the LOAD value rather than an arbitrary value when the timer is enabled.

The following examples illustrate selecting SysTick timer reload values for different system configurations. All of the examples calculate an interrupt interval of 10 milliseconds, as the SysTick timer is intended to be used, and there are no rounding errors.

#### System clock = 72 MHz

Program the CTRL register with the value 0x7 which selects the system clock as the clock source and enables the SysTick timer and the SysTick timer interrupt.

RELOAD = (system clock frequency  $\times$  10 ms) -1 = (72 MHz  $\times$  10 ms) -1 = 720000 -1 = 719999 = 0x000A FC7F

#### System tick timer clock = 24 MHz

Program the CTRL register with the value 0x3 which selects the clock from the system tick clock divider (use DIV = 3) as the clock source and enables the SysTick timer and the SysTick timer interrupt.

RELOAD = (system tick timer clock frequency  $\times$  10 ms) -1 = (24 MHz  $\times$  10 ms) -1 = 240000 -1 = 239999 = 0x0003A97F

#### System clock = 12 MHz

Program the CTRL register with the value 0x7 which selects the system clock as the clock source and enables the SysTick timer and the SysTick timer interrupt.

In this case the system clock is derived from the IRC clock.

RELOAD = (system clock frequency  $\times$  10 ms) -1 = (12 MHz  $\times$  10 ms) -1 = 120000 -1 = 119999 = 0x0001 D4BF

## UM10524

# Chapter 19: LPC1315/16/17/45/46/47 Repetitive Interrupt Timer (RI timer)

Rev. 4 — 12 March 2013

**User manual** 

### 19.1 How to read this chapter

The RI timer is available on all LPC1315/16/17/45/46/47 parts.

### 19.2 Basic configuration

The RI timer is always running.

#### 19.3 Features

- 48-bit counter running from the main clock. Counter can be free-running or be reset by a generated interrupt.
- 48-bit compare value.
- 48-bit compare mask. An interrupt is generated when the counter value equals the compare value, after masking. This allows for combinations not possible with a simple compare.

### 19.4 General description

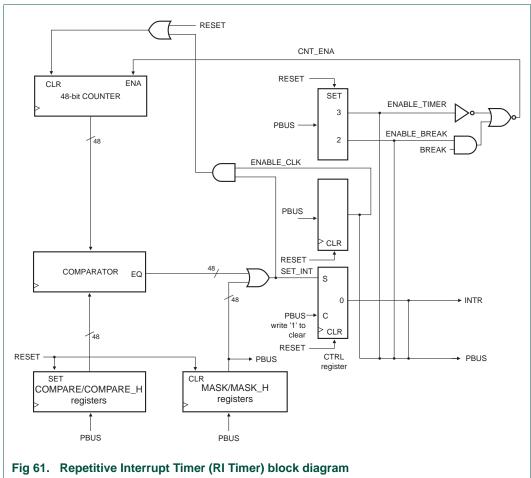

The Repetitive Interrupt Timer (RIT) provides a versatile means of generating interrupts at specified time intervals, without using a standard timer. It is intended for repeating interrupts that aren't related to Operating System interrupts. The RIT could also be used as an alternative to the Cortex-M3 System Tick Timer if there are different system requirements.

The RI timer can be used in conjunction with the Embedded Trace Macrocell (ETM) of the ARM Cortex-M3; v. r2p1) for ETM timestamping. The RI timer allows periodic insertion of a time value based on specific events (exceptions, return from exceptions, trace FIFO flush) into the trace data stream of the ETM. With the ETM timestamping feature, multiple trace data streams can be correlated to obtain a rough measure of code performance.

Bit	Symbol	Description	Reset value
15:0	RICOUNTER	16 LSBs of the up counter. Counts continuously unless RITEN bit in RICTRL register is cleared or debug mode is entered (if enabled by the RITNEBR bit in RICTRL). Can be loaded to any value in software.	0
31:16	-	Reserved.	-

#### Chapter 19: LPC1315/16/17/45/46/47 Repetitive Interrupt Timer (RI

### 19.6 RI timer operation

Following reset, the counter begins counting up from 0. Whenever the counter value equals the 48-bit value programmed into the COMPVAL and COMPVAL\_H registers, the interrupt flag will be set. Any bit or combination of bits can be removed from this comparison (i.e. forced to compare) by writing a 1 to the corresponding bit(s) in the MASK and MASK\_H registers. If the RITENCLR bit is low (default state), a valid comparison ONLY causes the interrupt flag to be set. It has no effect on the count sequence. Counting continues as usual. When the counter reaches 0xFFFF FFFF it rolls-over to 0 on the next clock and continues counting. If the RITENCLR bit is set to 1 a valid comparison will also cause the counter to be reset to zero. Counting will resume from there on the next clock edge.

Counting can be halted in software by writing a '0' to the RITEN bit. Counting will also be halted when the processor is halted for debugging provided the RITENBR bit is set. Both the RITEN and RITENBR bits are set on reset.

The interrupt flag can be cleared in software by writing a 1 to the RITINT bit.

Software must stop the counter before reloading it with a new value.

The counter (COUNTER/COUNTER\_H), COMPVAL/COMPVAL\_H registers, MASK/MASK\_H registers, and the CTRL register can all be read by software at any time.

## **UM10524**

## Chapter 20: LPC1315/16/17/45/46/47 ADC

Rev. 4 — 12 March 2013

**User manual** 

### 20.1 How to read this chapter

The ADC block is identical for all LPC1315/16/17/45/46/47 parts.

For better immunity to noise, the VREFN/P and V<sub>DDA</sub>/V<sub>SSA</sub> are pinned out on the LQFP64 package. For the LQFP48 and HVQFN33 pin packages, use  $V_{DD}$  and  $V_{SS}$  for the ADC reference pins.

### 20.2 Basic configuration

The ADC is configured using the following registers:

- 1. Pins: The ADC pin functions are configured in the IOCON register block (Table 55).
- 2. Power and peripheral clock: In the SYSAHBCLKCTRL register, set bit 13 (Table 19). Power to the ADC is controlled through the PDRUNCFG register (Table 42).

Remark: Basic clocking for the A/D converters is provided by the APB clock. A programmable divider is included in each converter to scale this clock to the clock (maximum 15.5 MHz in 12-bit mode or 31 MHz in 10-bit mode (BURST bit = 0)) needed by the successive approximation process. A fully accurate conversion requires 31 of these clocks.

#### 20.3 Features

- 12-bit successive approximation Analog-to-Digital Converter (ADC).
- · Input multiplexing among 8 pins.
- Power-down mode (see PDRUNCFG register in the SYSCON block (Table 42).
- Low power mode.
- Measurement range VREFN to VREFP (or 0 V to VDD for pin packages without VREFP and VREFN pins). Do not exceed the V<sub>DD</sub> voltage level.
- 12-bit conversion rate of 500 kSamples/s.
- 10-bit, double conversion rate mode (up to 1 Msamples/s).
- Burst conversion mode for single or multiple inputs.
- Optional conversion on transition on input pin or Timer Match signal.

### 20.4 Pin description

Table 332 gives a brief summary of the ADC related pins.

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Table 332. ADC pin description

Pin	Туре	Description
AD[7:0]	Input	<b>Analog Inputs.</b> The A/D converter cell can measure the voltage on any of these input signals.
		<b>Remark:</b> While the pins are 5 V tolerant in digital mode, the maximum input voltage must not exceed $V_{DD}$ when the pins are configured as analog inputs.
VREFP, VREFN	Reference	Voltage References. These pins provide a voltage reference level for the ADC. Note: VREFP should be tied to VDD(3V3) and VREFN should be tied to VSS if the ADC is not used.
$V_{DD}$ , $V_{DDA}$	Power	Analog Power and Ground. These should typically be the same voltages as VDD and VSS, but should be isolated to minimize noise and error. Note: $V_{DDA}$ should be tied to VDD and VSSA should be tied to VSS if the ADC is not used.

The ADC function must be selected via the IOCON registers in order to get accurate voltage readings on the monitored pin. For a pin hosting an ADC input, it is not possible to have a have a digital function selected and yet get valid ADC readings. An inside circuit disconnects ADC hardware from the associated pin whenever a digital function is selected on that pin.

### 20.5 Register description

The ADC contains registers organized as shown in <u>Table 333</u>.

Table 333. Register overview: ADC (base address 0x4001 C000)

Name	Access	Address offset	Description	Reset Value <sup>[1]</sup>	Reference
CR	R/W	0x000	A/D Control Register. The CR register must be written to select the operating mode before A/D conversion can occur.	0x0000 0000	Table 334
GDR	R/W	0x004	A/D Global Data Register. Contains the result of the most recent A/D conversion.	NA	Table 335
-	-	800x0	Reserved.	-	-
INTEN	R/W	0x00C	A/D Interrupt Enable Register. This register contains enable bits that allow the DONE flag of each A/D channel to be included or excluded from contributing to the generation of an A/D interrupt.	0x0000 0100	Table 336
DR0	R/W	0x010	A/D Channel 0 Data Register. This register contains the result of the most recent conversion completed on channel 0	NA	Table 337

DR7	R/W	0x02C	A/D Channel 7 Data Register. This register contains the result of the most recent conversion completed on channel 7.	NA	Table 337
STAT	RO	0x030	A/D Status Register. This register contains DONE and OVERRUN flags for all of the A/D channels, as well as the A/D interrupt flag.	0	Table 338
TRM	R/W	0x034	A/D trim register	0xF00	Table 339

<sup>[1]</sup> Reset Value reflects the data stored in used bits only. It does not include reserved bits content.

### 20.5.1 A/D Control Register (CR)

The A/D Control Register provides bits to select A/D channels to be converted, A/D timing, A/D modes, and the A/D start trigger.

Table 334. A/D Control Register (CR - address 0x4001 C000) bit description

Bit	Symbol	Value	Description	Reset Value	
7:0	SEL		Selects which of the AD7:0 pins is (are) to be sampled and converted. Bit 0 selects Pin AD0, bit 1 selects pin AD1,, and bit 7 selects pin AD7. In software-controlled mode (BURST = 0), only one channel can be selected, i.e. only one of these bits should be 1. In hardware scan mode (BURST = 1), any numbers of channels can be selected, i.e any or all bits can be set to 1. If all bits are set to 0, channel 0 is selected automatically (SEL = 0x01).	0x00	
15:8	CLKDIV		The main clock (PCLK_ADC) is divided by (this value plus one) to produce the clock for the A/D converter. The clock should be less than or equal to 15.5 MHz (12-bit mode) or 31 MHz (10-bit mode) in software-controlled mode (BURST bit = 0). Typically, software should program the smallest value in this field that yields a clock of 15.5 MHz or slightly less, but in certain cases (such as a high-impedance analog source) a slower clock may be desirable.	0	
16	BURST		Burst mode	0	
			<b>Remark:</b> If BURST is set to 1, the ADGINTEN bit in the INTEN register ( <u>Table 336</u> ) must be set to 0.		
		0	Software-controlled mode: Conversions are software-controlled and require 31 clocks.		
		1	Hardware scan mode: The AD converter does repeated conversions at the rate selected by the CLKS field, scanning (if necessary) through the pins selected by ones in the SEL field. The first conversion after the start corresponds to the least-significant bit set to 1 in the SEL field, then the next higher bits (pins) set to one are scanned if applicable. Repeated conversions can be terminated by clearing this bit, but the conversion in progress when this bit is cleared will be completed.		
			<b>Important:</b> START bits must be 000 when BURST = 1, or conversions will not start.		
20:17	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-	
21	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-	

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Table 334. A/D Control Register (CR - address 0x4001 C000) bit description

Bit	Symbol	Value	Description	Rese Value
22	LPWRMODE		Low-power mode	0 0
		0	Disable the low-power ADC mode. The analog circuitry remains activated when no conversions are requested.	
		1	Enable the low-power ADC mode. The analog circuitry is automatically powered-down when no conversions are taking place. When any (hardware or software) triggering event is detected, the analog circuitry is enabled. After the required start-up time, the requested conversion will be launched. Once the conversion completes, the analog-circuitry will again be powered-down provided no further conversions are pending.  Remark: This mode will NOT power-up the A/D if the ADC is powered down (ADC_PD bit in the PDRUNCFG register is HIGH) or if the part is in Deep-sleep, Power-down, or Deep power-down mode.	
23	MODE10BIT		10-bit conversion rate mode	
		0	Disable the 10-bit conversion rate mode.	
		is reduced to 10 bits (the two LSB of the conversion result will be forced to 0	Enable the 10-bit conversion rate mode with high conversion rate. The A/D resolution is reduced to 10 bits (the two LSB of the conversion result will be forced to 0). The clock rate (set via the CLKDIV field) can be doubled to up to 31 MHz to achieve a conversion rate of up to one million samples per second.	
26:24	START		When the BURST bit is 0, these bits control whether and when an A/D conversion is started:	0
		0x0	No start (this value should be used when clearing PDN to 0).	0
		0x1	Start conversion now.	
		0x2	Start conversion when the edge selected by bit 27 occurs on capture channel 0 of the 16-bit counter/timer0 (CT16B0_CAP0, independently of the pinout).	0
		0x3	Start conversion when the edge selected by bit 27 occurs on capture channel 0 of the 32-bit counter/timer0 (CT32B0_CAP0, independently of the pinout).	
		0x4	Start conversion when the edge selected by bit 27 occurs on CT32B0_MAT0[1].	
		0x5	Start conversion when the edge selected by bit 27 occurs on CT32B0_MAT1[1].	
		0x6	Start conversion when the edge selected by bit 27 occurs on CT16B0_MAT0[1].	
		0x7	Start conversion when the edge selected by bit 27 occurs on CT16B0_MAT1[1].	
27	EDGE		Edge control. This bit is significant only when the START field contains 010-111.	0
		0	Start conversion on a rising edge on the selected CAP/MAT signal.	
		1	Start conversion on a falling edge on the selected CAP/MAT signal.	
31:28	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

<sup>[1]</sup> Note that this does not require that the timer match function appear on a device pin.

### 20.5.2 A/D Global Data Register (GDR)

The A/D Global Data Register contains the result of the most recent A/D conversion. This includes the data, DONE, and Overrun flags, and the number of the A/D channel to which the data relates.

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Table 335. A/D Global Data Register (GDR - address 0x4001 C004) bit description

Bit	Symbol	Description	Reset Value
3:0	-	Reserved. These bits always read as zeros.	0
15:4	V_VREF	When DONE is 1, this field contains a binary fraction representing the voltage on the ADn pin selected by the SEL field, divided by the voltage on the $V_{DD}$ pin or as it falls within the range of VREFP to VREFN. Zero in the field indicates that the voltage on the ADn pin was less than, equal to, or close to that on $V_{SS}/VREFN$ , while 0xFFF indicates that the voltage on ADn was close to, equal to, or greater than that on $V_{DD}/VREFP$ .	X
23:16	-	Reserved. These bits always read as zeros.	0
26:24	CHN	These bits contain the channel from which the result bits V_VREF were converted.	X
29:27	-	Reserved. These bits always read as zeros.	0
30	OVERRUN	This bit is 1 in burst mode if the results of one or more conversions was (were) lost and overwritten before the conversion that produced the result in the V_VREF bits.	0
31	DONE	This bit is set to 1 when an A/D conversion completes. It is cleared when this register is read and when the ADCR is written. If the ADCR is written while a conversion is still in progress, this bit is set and a new conversion is started.	0

#### 20.5.3 A/D Interrupt Enable Register (INTEN)

This register allows control over which A/D channels generate an interrupt when a conversion is complete. For example, it may be desirable to use some A/D channels to monitor sensors by continuously performing conversions on them. The most recent results are read by the application program whenever they are needed. In this case, an interrupt is not desirable at the end of each conversion for some A/D channels.

Table 336. A/D Interrupt Enable Register (INTEN - address 0x4001 C00C) bit description

Bit	Symbol	Description	Reset Value
7:0	ADINTEN	These bits allow control over which A/D channels generate interrupts for conversion completion. When bit 0 is one, completion of a conversion on A/D channel 0 will generate an interrupt, when bit 1 is one, completion of a conversion on A/D channel 1 will generate an interrupt, etc.	0x00
8	ADGINTEN	When 1, enables the global DONE flag in ADDR to generate an interrupt. When 0, only the individual A/D channels enabled by ADINTEN 7:0 will generate interrupts.	1
		<b>Remark:</b> This bit must be set to 0 in burst mode (BURST = 1 in the CR register).	
31:9	-	Reserved. Unused, always 0.	0

#### 20.5.4 A/D Data Registers (DR0 to DR7)

The A/D Data Register hold the result when an A/D conversion is complete, and also include the flags that indicate when a conversion has been completed and when a conversion overrun has occurred.

360 of 416

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Table 337. A/D Data registers (DR0 to DR7 - addresses 0x4001 C010 to 0x4001 C02C) bit description

Bit	Symbol	Description	Reset Value
3:0	-	Reserved.	0
15:4	V_VREF	When DONE is 1, this field contains a binary fraction representing the voltage on the ADn pin as it falls within the range of VREFP to VREFN. Zero in the field indicates that the voltage on the ADn pin was less than, equal to, or close to that on VREFN/V $_{\rm SS}$ , while 0xFFF indicates that the voltage on AD input was close to, equal to, or greater than that on VREFP/VDD.	NA
29:16	-	Reserved.	0
30	OVERRUN	This bit is 1 in burst mode if the results of one or more conversions was (were) lost and overwritten before the conversion that produced the result in the V_VREF bits. This bit is cleared by reading this register.	0
31	DONE	This bit is set to 1 when an A/D conversion completes. It is cleared when this register is read.	0

#### 20.5.5 A/D Status Register (STAT)

The A/D Status register allows checking the status of all A/D channels simultaneously. The DONE and OVERRUN flags appearing in the DRn register for each A/D channel are mirrored in ADSTAT. The interrupt flag (the logical OR of all DONE flags) is also found in ADSTAT.

Table 338. A/D Status Register (STAT - address 0x4001 C030) bit description

Bit	Symbol	Description	Reset Value
7:0	DONE	These bits mirror the DONE status flags that appear in the result register for each A/D channel n.	0
15:8	OVERRUN	These bits mirror the OVERRRUN status flags that appear in the result register for each A/D channel n. Reading ADSTAT allows checking the status of all A/D channels simultaneously.	0
16	ADINT	This bit is the A/D interrupt flag. It is one when any of the individual A/D channel Done flags is asserted and enabled to contribute to the A/D interrupt via the ADINTEN register.	0
31:17	-	Reserved. Unused, always 0.	0

## 20.5.6 A/D Trim register (TRM)

This register will be set by the boot code on start-up. It contains the trim values for the DAC and the ADC. The offset trim values for the ADC can be overwritten by the user. All 12 bits are visible when this register is read.

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Table 339. A/D Trim register (TRM - address 0x4001 C034) bit description
--

Bit	Symbol	Description	Reset value
3:0	-	Reserved.	NA
7:4	ADCOFFS	Offset trim bits for ADC operation. Initialized by the boot code. Can be overwritten by the user.	0
11:8	TRIM	Written-to by boot code. Can <b>not</b> be overwritten by the user. These bits are locked after boot code write.	1111
31:12	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	-

## 20.6 Operation

#### 20.6.1 Hardware-triggered conversion

If the BURST bit in the ADCR0 is 0 and the START field contains 010-111, the A/D converter will start a conversion when a transition occurs on a selected pin or timer match signal.

#### 20.6.2 Interrupts

An interrupt is requested to the interrupt controller when the ADINT bit in the ADSTAT register is one. The ADINT bit is one when any of the DONE bits of A/D channels that are enabled for interrupts (via the ADINTEN register) are one. Software can use the Interrupt Enable bit in the interrupt controller that corresponds to the ADC to control whether this results in an interrupt. The result register for an A/D channel that is generating an interrupt must be read in order to clear the corresponding DONE flag.

#### 20.6.3 Accuracy vs. digital receiver

While the A/D converter can be used to measure the voltage on any ADC input pin, regardless of the pin's setting in the IOCON block, selecting the ADC in the IOCON registers function improves the conversion accuracy by disabling the pin's digital receiver (see also Section 7.3.7).

#### 20.6.4 Optional operating modes

There are two optional modes of A/D operation which may be selected in the CR register:

- The 10-bit mode. In this mode two bits of ADC accuracy are sacrificed in order to double the conversion rate. The maximum ADC clock rate when this mode is selected is increased to 31 MHz (BURST bit = 0). The two LSB of the conversion result will be forced to 00 when this mode is enabled.
- 2. The low-power mode. When this mode is selected, the analog portions of the ADC are automatically shut down when no conversions are in progress. The ADC is automatically restarted whenever any hardware or software triggering event occurs (provided the ADC is not powered down in the PDRUNCFG register or the part is in Deep-sleep, Power-down, or Deep power-down mode). When the requested conversion completes, the analog ADC circuitry will be returned to its power-down state unless a new conversion is pending. Setting the BURST bit will override low-power mode and prevent the ADC from being automatically powered down.

#### Chapter 20: LPC1315/16/17/45/46/47 ADC

Low power mode can save an appreciable amount of power when the ADC is not in continuous use at the expense of a delay between the trigger event and the onset of sampling and conversion.

These two optional modes are not mutually exclusive.

LPC1346FBD48	48	4	yes	yes
LPC1347FHN33	64	4	yes	yes
LPC1347FBD48	64	4	yes	yes
LPC1347FBD64	64	4	yes	yes
LPC1315FHN33	32	2	yes	no
LPC1315FBD48	32	2	yes	no
LPC1316FHN33	48	4	yes	no
LPC1316FBD48	48	4	yes	no
LPC1317FHN33	64	4	yes	no
LPC1317FBD48	64	4	yes	no
LPC1317FBD64	64	4	yes	no

**Remark:** In addition to the ISP and IAP commands, a register can be accessed in the flash controller block to configure flash memory access times, see Section 21.16.1.

## 21.2 Bootloader

The bootloader controls initial operation after reset and also provides the means to program the flash memory. This could be initial programming of a blank device, erasure and re-programming of a previously programmed device, or programming of the flash memory by the application program in a running system.

The bootloader version can be read by ISP/IAP calls (see <u>Section 21.13.12</u> or <u>Section 21.14.6</u>).

#### 21.3 Features

- In-System Programming: In-System programming (ISP) is programming or reprogramming the on-chip flash memory, using the bootloader software and the UART serial port. This can be done when the part resides in the end-user board.
- In Application Programming: In-Application (IAP) programming is performing erase and write operation on the on-chip flash memory, as directed by the end-user application code.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

- Small size (256 B) page erase programming.
- Flash access times can be configured through a register in the flash controller block.
- Erase time for one sector is 100 ms  $\pm$  5%. Programming time for one block of 256 bytes is 1 ms  $\pm$  5%.

## 21.4 Description

The bootloader code is executed every time the part is powered on or reset (see Figure 62). The loader can execute the ISP command handler or the user application code. A LOW level during reset at the PIO0\_1 pin is considered an external hardware request to start the ISP command handler (or, on the LPC1345/46/47, the USB device handler if pin PIO0\_3 is HIGH) without checking for a valid user code first.

Assuming that power supply pins are at their nominal levels when the rising edge on RESET pin is generated, it may take up to 3 ms before PIOO\_1 is sampled and the decision whether to continue with user code or ISP handler is made. If PIOO\_1 is sampled LOW and the watchdog overflow flag is set, the external hardware request to start the ISP command handler is ignored. If there is no request for the ISP command handler execution (PIOO\_1 is sampled HIGH after reset), a search is made for a valid user program. If a valid user program is found then the execution control is transferred to it. If a valid user program is not found, the auto-baud routine is invoked.

For the LPC1345/46/47 parts, the state of PIO0\_3 determines whether the UART or USB interface will be used:

- If PIOO\_3 is sampled HIGH, the bootloader connects the LPC1345/46/47 as a MSC USB device to a PC host. The LPC1345/46/47 flash memory space is represented as a drive in the host's operating system.
- If PIO0\_3 is sampled LOW, the bootloader configures the UART serial port using pins PIO0\_18 and PIO0\_19 for RXD and TXD and calls the ISP command handler.

**Remark:** The sampling of pin PIOO\_1 can be disabled through programming flash location 0x0000 02FC (see Section 21.12.1).

## 21.5 Memory map after any reset

The boot block is 16 kB in size and is located in the memory region starting from the address 0x1FFF 0000. The bootloader is designed to run from this memory area, but both the ISP and IAP software use parts of the on-chip RAM. The RAM usage is described later in this chapter. The interrupt vectors residing in the boot block of the on-chip flash memory also become active after reset, i.e., the bottom 512 bytes of the boot block are also visible in the memory region starting from the address 0x0000 0000.

## 21.6 Flash content protection mechanism

The LPC1315/16/17/45/46/47 is equipped with the Error Correction Code (ECC) capable Flash memory. The purpose of an error correction module is twofold. Firstly, it decodes data words read from the memory into output data words. Secondly, it encodes data words to be written to the memory. The error correction capability consists of single bit error correction with Hamming code.

UM10524

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

The operation of ECC is transparent to the running application. The ECC content itself is stored in a flash memory not accessible by user's code to either read from it or write into it on its own. A byte of ECC corresponds to every consecutive 128 bits of the user accessible Flash. Consequently, Flash bytes from 0x0000 0000 to 0x0000 000F are protected by the first ECC byte, Flash bytes from 0x0000 0010 to 0x0000 001F are protected by the second ECC byte, etc.

Whenever the CPU requests a read from user's Flash, both 128 bits of raw data containing the specified memory location and the matching ECC byte are evaluated. If the ECC mechanism detects a single error in the fetched data, a correction will be applied before data are provided to the CPU. When a write request into the user's Flash is made, write of user specified content is accompanied by a matching ECC value calculated and stored in the ECC memory.

When a sector of Flash memory is erased, the corresponding ECC bytes are also erased. Once an ECC byte is written, it can not be updated unless it is erased first. Therefore, for the implemented ECC mechanism to perform properly, data must be written into the flash memory in groups of 16 bytes (or multiples of 16), aligned as described above.

#### 21.7 Criterion for Valid User Code

The reserved ARM Cortex-M3 exception vector location 7 (offset 0x0000 001C in the vector table) should contain the 2's complement of the check-sum of table entries 0 through 6. This causes the checksum of the first 8 table entries to be 0. The bootloader code checksums the first 8 locations in sector 0 of the flash. If the result is 0, then execution control is transferred to the user code.

If the signature is not valid, the auto-baud routine synchronizes with the host via the serial port (UART).

If the UART is selected, the host should send a '?' (0x3F) as a synchronization character and wait for a response. The host side serial port settings should be 8 data bits, 1 stop bit and no parity. The auto-baud routine measures the bit time of the received synchronization character in terms of its own frequency and programs the baud rate generator of the serial port. It also sends an ASCII string ("Synchronized<CR><LF>") to the host. In response to this host should send the same string ("Synchronized<CR><LF>"). The auto-baud routine looks at the received characters to verify synchronization. If synchronization is verified then "OK<CR><LF>" string is sent to the host. Host should respond by sending the crystal frequency (in kHz) at which the part is running. For example, if the part is running at 10 MHz, the response from the host should be "10000<CR><LF>". "OK<CR><LF>" string is sent to the host after receiving the crystal frequency. If synchronization is not verified then the auto-baud routine waits again for a synchronization character. For auto-baud to work correctly in case of user invoked ISP, the CCLK frequency should be greater than or equal to 10 MHz. In USART ISP mode, the LPC1315/16/17/45/46/47 is clocked by the IRC and the crystal frequency is ignored.

Once the crystal frequency is received the part is initialized and the ISP command handler is invoked. For safety reasons an "Unlock" command is required before executing the commands resulting in flash erase/write operations and the "Go" command. The rest of

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

the commands can be executed without the unlock command. The Unlock command is required to be executed once per ISP session. The Unlock command is explained in Section 21.13 "ISP commands" on page 374.

## 21.8 ISP/IAP communication protocol

All ISP commands should be sent as single ASCII strings. Strings should be terminated with Carriage Return (CR) and/or Line Feed (LF) control characters. Extra <CR> and <LF> characters are ignored. All ISP responses are sent as <CR><LF> terminated ASCII strings. Data is sent and received in UU-encoded format.

#### 21.8.1 ISP command format

"Command Parameter\_0 Parameter\_1 ... Parameter\_n<CR><LF>" "Data" (Data only for Write commands).

#### 21.8.2 ISP response format

"Return\_Code<CR><LF>Response\_0<CR><LF>Response\_1<CR><LF>...
Response\_n<CR><LF>"Data" (Data only for Read commands).

#### 21.8.3 ISP data format

The data stream is in UU-encoded format. The UU-encode algorithm converts 3 bytes of binary data in to 4 bytes of printable ASCII character set. It is more efficient than Hex format which converts 1 byte of binary data in to 2 bytes of ASCII hex. The sender should send the check-sum after transmitting 20 UU-encoded lines. The length of any UU-encoded line should not exceed 61 characters (bytes) i.e. it can hold 45 data bytes. The receiver should compare it with the check-sum of the received bytes. If the check-sum matches then the receiver should respond with "OK<CR><LF>" to continue further transmission. If the check-sum does not match the receiver should respond with "RESEND<CR><LF>". In response the sender should retransmit the bytes.

#### 21.8.4 ISP flow control

A software XON/XOFF flow control scheme is used to prevent data loss due to buffer overrun. When the data arrives rapidly, the ASCII control character DC3 (stop) is sent to stop the flow of data. Data flow is resumed by sending the ASCII control character DC1 (start). The host should also support the same flow control scheme.

#### 21.8.5 ISP command abort

Commands can be aborted by sending the ASCII control character "ESC". This feature is not documented as a command under "ISP Commands" section. Once the escape code is received the ISP command handler waits for a new command.

#### 21.8.6 Interrupts during ISP

The boot block interrupt vectors located in the boot block of the flash are active after any reset.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.8.7 Interrupts during IAP

The on-chip flash memory is not accessible during erase/write operations. When the user application code starts executing, the interrupt vectors from the user flash area are active. Before making any IAP call, either disable the interrupts or ensure that the user interrupt vectors are active in RAM and that the interrupt handlers reside in RAM. The IAP code does not use or disable interrupts.

## 21.8.8 RAM used by ISP command handler

ISP commands use on-chip RAM from  $0x1000\ 017C$  to  $0x1000\ 025B$ . The user could use this area, but the contents may be lost upon reset. Flash programming commands use the top 32 bytes of on-chip RAM. The stack is located at RAM top - 32 bytes. The maximum stack usage is 256 bytes and grows downwards.

#### 21.8.9 RAM used by IAP command handler

Flash programming commands use the top 32 bytes of on-chip RAM. The maximum stack usage in the user allocated stack space is 128 bytes and grows downwards.

## 21.9 USB communication protocol

The LPC1345/46/47 is enumerated as a Mass Storage Class (MSC) device to a PC or another embedded system. In order to connect via the USB interface, the part must use the external crystal at a frequency of 12 MHz. The MSC device presents an easy integration with the PC's operating system. The flash memory space is represented as a drive in the host file system. The entire available user flash is mapped to a file of the size of the LPC1345/46/47 flash in the host's folder with the default name 'firmware.bin'. The 'firmware.bin' file can be deleted and a new file can be copied into the directory, thereby updating the user code in flash. Note that the filename of the new flash image file is not important. After a reset or a power cycle, the new file is visible in the host's file system under it's default name 'firmware.bin'.

The code read protection (CRP, see <u>Table 341</u>) level determines how the flash is reprogrammed:

If CRP1 or CRP2 is enabled, the user flash is erased when the file is deleted.

If CRP1 is enabled or no CRP is selected, the user flash is erased and reprogrammed when the new file is copied. However, only the area occupied by the new file is erased and reprogrammed.

**Remark:** The only commands supported for the LPC1345/46/47 flash image folder are copy and delete.

Three Code Read Protection (CRP) levels can be enabled for flash images updated through USB (see <u>Section 21.12</u> for details). The volume label on the MSCD indicates the CRP status.

368 of 416

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 341. CRP levels for USB boot images

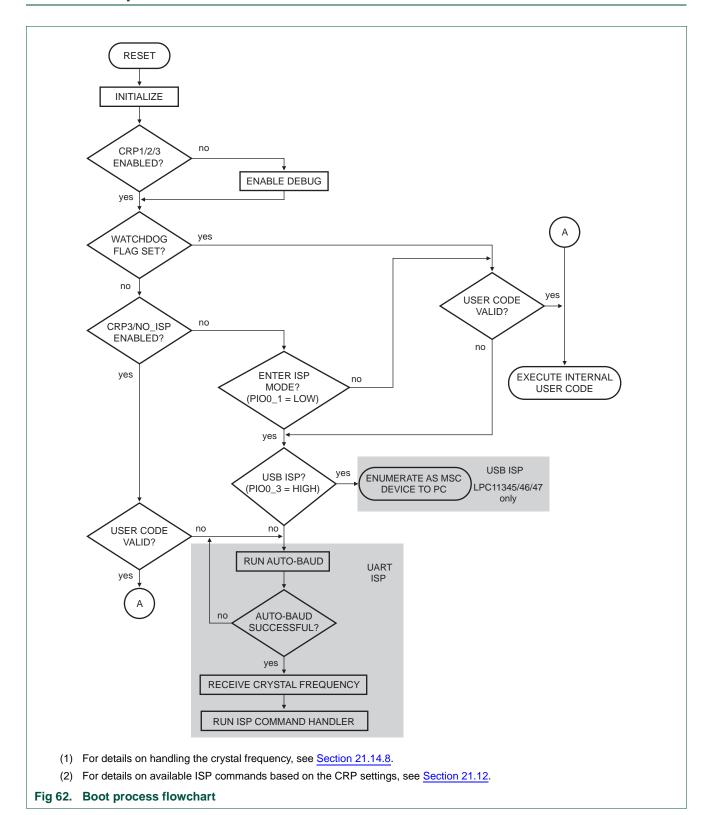

CRP status	Volume label	Description
No CRP	CRP DISABLD	The user flash can be read or written.
CRP1	CRP1 ENABLD	The user flash content cannot be read but can be updated. The flash memory sectors are updated depending on the new firmware image.
CRP2	CRP2 ENABLD	The user flash content cannot be read but can be updated. The entire user flash memory is erased before writing the new firmware image.
CRP3	CRP3 ENABLD	The user flash content cannot be read or updated. The bootloader always executes the user application if valid.

## 21.9.1 Usage note

When programming flash images via Flash Magic or Serial Wire Debugger (SWD), the user code valid signature is automatically inserted by the programming utility. When using USB ISP, the user code valid signature must be either part of the vector table, or the axf or binary file must be post-processed to insert the checksum.

## 21.10 Boot process flowchart

UM10524

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.11 Sector numbers

Some IAP and ISP commands operate on sectors and specify sector numbers. In addition, the LPCLPC1315/16/17/45/46/47 support a page erase command. The following table shows the correspondence between page numbers, sector numbers, and memory addresses for LPC1315/16/17/45/46/47 devices.

The size of a sector is 4 kB, the size of a page is 256 Byte. One sector contains 16 pages.

Table 342. LPC1315/16/17/45/46/47 flash sectors

Sector number	Sector size [kB]	Page number	Address range	LPC1345/ LPC1315	LPC1346/ LPC1316	LPC1347/ LPC1317
0	4	0 -15	0x0000 0000 - 0x0000 0FFF	yes	yes	yes
1	4	16 - 31	0x0000 1000 - 0x0000 1FFF	yes	yes	yes
2	4	32 - 47	0x0000 2000 - 0x0000 2FFF	yes	yes	yes
3	4	48 - 63	0x0000 3000 - 0x0000 3FFF	yes	yes	yes
4	4	64 - 79	0x0000 4000 - 0x0000 4FFF	yes	yes	yes
5	4	80 - 95	0x0000 5000 - 0x0000 5FFF	yes	yes	yes
6	4	96 - 111	0x0000 6000 - 0x0000 6FFF	yes	yes	yes
7	4	112 - 127	0x0000 7000 - 0x0000 7FFF	yes	yes	yes
8	4	128 - 143	0x0000 8000 - 0x0000 8FFF	no	yes	yes
9	4	144 - 159	0x0000 9000 - 0x0000 9FFF	no	yes	yes
10	4	160 - 175	0x0000 A000 - 0x0000 AFFF	no	yes	yes
11	4	176 - 191	0x0000 B000 - 0x0000 BFFF	no	yes	yes
12	4	192 - 207	0x0000 C000 - 0x0000 CFFF	no	no	yes
13	4	208 - 223	0x0000 D000 - 0x0000 DFFF	no	no	yes
14	4	224 - 239	0x0000 E000 - 0x0000 EFFF	no	no	yes
15	4	240 - 255	0x0000 F000 - 0x0000 FFFF	no	no	yes

## 21.12 Code Read Protection (CRP)

Code Read Protection is a mechanism that allows the user to enable different levels of security in the system so that access to the on-chip flash and use of the ISP can be restricted. When needed, CRP is invoked by programming a specific pattern in flash location at 0x0000 02FC. IAP commands are not affected by the code read protection.

Important: any CRP change becomes effective only after the device has gone through a power cycle.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 343. Code Read Protection (CRP) options

Name	Pattern programmed in 0x0000 02FC	Description
NO_ISP	0x4E69 7370	Prevents sampling of pin PIO0_1 for entering ISP mode. PIO0_1 is available for other uses.
CRP1	0x12345678	Access to chip via the SWD pins is disabled. This mode allows partial flash update using the following ISP commands and restrictions:
		<ul> <li>Write to RAM command cannot access RAM below 0x1000 0300.</li> </ul>
		<ul> <li>Copy RAM to flash command can not write to Sector 0.</li> </ul>
		<ul> <li>Erase command can erase Sector 0 only when all sectors are selected for erase.</li> </ul>
		Compare command is disabled.
		<ul> <li>Read Memory command is disabled.</li> </ul>
		This mode is useful when CRP is required and flash field updates are needed but all sectors can not be erased. Since compare command is disabled in case of partial updates the secondary loader should implement checksum mechanism to verify the integrity of the flash.
CRP2	0x87654321	Access to chip via the SWD pins is disabled. The following ISP commands are disabled:
		Read Memory
		Write to RAM
		• Go
		<ul> <li>Copy RAM to flash</li> </ul>
		Compare
		When CRP2 is enabled the ISP erase command only allows erasure of all user sectors.
CRP3	0x43218765	Access to chip via the SWD pins is disabled. ISP entry by pulling PIO0_1 LOW is disabled if a valid user code is present in flash sector 0.
		This mode effectively disables ISP override using PIO0_1 pin. It is up to the user's application to provide a flash update mechanism using IAP calls or call reinvoke ISP command to enable flash update via UART0.
		Caution: If CRP3 is selected, no future factory testing can be performed on the device.

Table 344. Code Read Protection hardware/software interaction

CRP option	User Code Valid	PIO0_1 pin at reset	SWD enabled	LPC1315/16/1 7/45/46/47 enters ISP mode	partial flash Update in ISP mode
None	No	x	Yes	Yes	Yes
None	Yes	High	Yes	No	NA
None	Yes	Low	Yes	Yes	Yes

CRP option	User Code Valid	PIO0_1 pin at reset	SWD enabled	LPC1315/16/1 7/45/46/47 enters ISP mode	partial flash Update in ISP mode
CRP2	Yes	High	No	No	NA
CRP2	Yes	Low	No	Yes	No
CRP3	Yes	х	No	No	NA
CRP1	No	Х	No	Yes	Yes
CRP2	No	Х	No	Yes	No
CRP3	No	Х	No	Yes	No

Table 345. ISP commands allowed for different CRP levels

ISP command	CRP1	CRP2	CRP3 (no entry in ISP mode allowed)
Unlock	yes	yes	n/a
Set Baud Rate	yes	yes	n/a
Echo	yes	yes	n/a
Write to RAM	yes; above 0x1000 0300 only	no	n/a
Read Memory	no	no	n/a
Prepare sector(s) for write operation	yes	yes	n/a
Copy RAM to flash	yes; not to sector 0	no	n/a
Go	no	no	n/a
Erase sector(s)	yes; sector 0 can only be erased when all sectors are erased.	yes; all sectors only	n/a
Blank check sector(s)	no	no	n/a
Read Part ID	yes	yes	n/a
Read Boot code version	yes	yes	n/a
Compare	no	no	n/a
ReadUID	yes	yes	n/a

In case a CRP mode is enabled and access to the chip is allowed via the ISP, an unsupported or restricted ISP command will be terminated with return code CODE\_READ\_PROTECTION\_ENABLED.

## 21.12.1 ISP entry protection

In addition to the three CRP modes, the user can prevent the sampling of pin PIO0\_1 for entering ISP mode and thereby release pin PIO0\_1 for other uses. This is called the NO\_ISP mode. The NO\_ISP mode can be entered by programming the pattern 0x4E69 7370 at location 0x0000 02FC.

The NO\_ISP mode is identical to the CRP3 mode except for SWD access, which is allowed in NO\_ISP mode but disabled in CRP3 mode. The NO\_ISP mode does not offer any code protection.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.13 ISP commands

The following commands are accepted by the ISP command handler. Detailed status codes are supported for each command. The command handler sends the return code INVALID\_COMMAND when an undefined command is received. Commands and return codes are in ASCII format.

CMD\_SUCCESS is sent by ISP command handler only when received ISP command has been completely executed and the new ISP command can be given by the host. Exceptions from this rule are "Set Baud Rate", "Write to RAM", "Read Memory", and "Go" commands.

Table 346. ISP command summary

ISP Command	Usage	Described in
Unlock	U <unlock code=""></unlock>	Table 347
Set Baud Rate	B <baud rate=""> <stop bit=""></stop></baud>	Table 348
Echo	A <setting></setting>	Table 349
Write to RAM	W <start address=""> <number bytes="" of=""></number></start>	Table 350
Read Memory	R <address> <number bytes="" of=""></number></address>	Table 351
Prepare sector(s) for write operation	P <start number="" sector=""> <end number="" sector=""></end></start>	<u>Table 352</u>
Copy RAM to flash	C <flash address=""> <ram address=""> <number bytes="" of=""></number></ram></flash>	Table 353
Go	G <address> <mode></mode></address>	Table 354
Erase sector(s)	E <start number="" sector=""> <end number="" sector=""></end></start>	Table 355
Blank check sector(s)	I <start number="" sector=""> <end number="" sector=""></end></start>	Table 356
Read Part ID	J	Table 357
Read Boot code version	К	Table 359
Compare	M <address1> <address2> <number bytes="" of=""></number></address2></address1>	Table 360
ReadUID	N	Table 361

#### 21.13.1 Unlock < Unlock code>

Table 347. ISP Unlock command

Command	U	
Input	Unlock code: 23130 <sub>10</sub>	
Return Code	CMD_SUCCESS	
	INVALID_CODE	
	PARAM_ERROR	
Description	This command is used to unlock Flash Write, Erase, and Go commands.	
Example	"U 23130 <cr><lf>" unlocks the Flash Write/Erase &amp; Go commands.</lf></cr>	

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.13.2 Set Baud Rate <Baud Rate> <stop bit>

Table 348. ISP Set Baud Rate command

Command	В	
Input	Baud Rate: 9600   19200   38400   57600   115200	
	Stop bit: 1   2	
Return Code	CMD_SUCCESS	
	INVALID_BAUD_RATE	
	INVALID_STOP_BIT	
	PARAM_ERROR	
Description	This command is used to change the baud rate. The new baud rate is effective after the command handler sends the CMD_SUCCESS return code.	
Example	"B 57600 1 <cr><lf>" sets the serial port to baud rate 57600 bps and 1 stop bit.</lf></cr>	

#### 21.13.3 Echo <setting>

Table 349. ISP Echo command

Command	A	
Input	Setting: ON = 1   OFF = 0	
Return Code	CMD_SUCCESS	
	PARAM_ERROR	
Description	The default setting for echo command is ON. When ON the ISP command handler sends the received serial data back to the host.	
Example	"A 0 <cr><lf>" turns echo off.</lf></cr>	

#### 21.13.4 Write to RAM <start address> <number of bytes>

The host should send the data only after receiving the CMD\_SUCCESS return code. The host should send the check-sum after transmitting 20 UU-encoded lines. The checksum is generated by adding raw data (before UU-encoding) bytes and is reset after transmitting 20 UU-encoded lines. The length of any UU-encoded line should not exceed 61 characters (bytes) i.e. it can hold 45 data bytes. When the data fits in less than 20 UU-encoded lines then the check-sum should be of the actual number of bytes sent. The ISP command handler compares it with the check-sum of the received bytes. If the check-sum matches, the ISP command handler responds with "OK<CR><LF>" to continue further transmission. If the check-sum does not match, the ISP command handler responds with "RESEND<CR><LF>". In response the host should retransmit the bytes.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 350. ISP Write to RAM command

Command	W	
Input	<b>Start Address:</b> RAM address where data bytes are to be written. This address should be a word boundary.	
	Number of Bytes: Number of bytes to be written. Count should be a multiple of 4	
Return Code	CMD_SUCCESS	
	ADDR_ERROR (Address not on word boundary)	
	ADDR_NOT_MAPPED	
	COUNT_ERROR (Byte count is not multiple of 4)	
	PARAM_ERROR	
	CODE_READ_PROTECTION_ENABLED	
Description	This command is used to download data to RAM. Data should be in UU-encoded format. This command is blocked when code read protection is enabled.	
Example	"W 268436224 4 <cr><lf>" writes 4 bytes of data to address 0x1000 0300.</lf></cr>	

#### 21.13.5 Read Memory <address> <no. of bytes>

The data stream is followed by the command success return code. The check-sum is sent after transmitting 20 UU-encoded lines. The checksum is generated by adding raw data (before UU-encoding) bytes and is reset after transmitting 20 UU-encoded lines. The length of any UU-encoded line should not exceed 61 characters (bytes) i.e. it can hold 45 data bytes. When the data fits in less than 20 UU-encoded lines then the check-sum is of actual number of bytes sent. The host should compare it with the checksum of the received bytes. If the check-sum matches then the host should respond with "OK<CR><LF>" to continue further transmission. If the check-sum does not match then the host should respond with "RESEND<CR><LF>". In response the ISP command handler sends the data again.

Table 351. ISP Read Memory command

Table 331. ISI	Table 331. 13F Read Methory Command	
Command	R	
Input	<b>Start Address:</b> Address from where data bytes are to be read. This address should be a word boundary.	
	Number of Bytes: Number of bytes to be read. Count should be a multiple of 4.	
Return Code	CMD_SUCCESS followed by <actual (uu-encoded)="" data="">  </actual>	
	ADDR_ERROR (Address not on word boundary)	
	ADDR_NOT_MAPPED	
	COUNT_ERROR (Byte count is not a multiple of 4)	
	PARAM_ERROR	
	CODE_READ_PROTECTION_ENABLED	
Description	This command is used to read data from RAM or flash memory. This command is blocked when code read protection is enabled.	
Example	"R 268435456 4 <cr><lf>" reads 4 bytes of data from address 0x1000 0000.</lf></cr>	

## 21.13.6 Prepare sector(s) for write operation <start sector number> <end sector number>

This command makes flash write/erase operation a two step process.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 352. ISP Prepare sector(s) for write operation command

	_	
Command	P	
Input	Start Sector Number	
	End Sector Number: Should be greater than or equal to start sector number.	
Return Code	CMD_SUCCESS	
	BUSY	
	INVALID_SECTOR	
	PARAM_ERROR	
Description	This command must be executed before executing "Copy RAM to flash" or "Erase Sector(s)" command. Successful execution of the "Copy RAM to flash" or "Erase Sector(s)" command causes relevant sectors to be protected again. The boot block can not be prepared by this command. To prepare a single sector use the same "Start" and "End" sector numbers.	
Example	"P 0 0 <cr><lf>" prepares the flash sector 0.</lf></cr>	

#### 21.13.7 Copy RAM to flash <Flash address> <RAM address> <no of bytes>

When writing to the flash, the following limitations apply:

- 1. The smallest amount of data that can be written to flash by the copy RAM to flash command is 256 byte (equal to one page).
- 2. One page consists of 16 flash words (lines), and the smallest amount that can be modified per flash write is one flash word (one line). This limitation follows from the application of ECC to the flash write operation, see Section 21.6.
- 3. To avoid write disturbance (a mechanism intrinsic to flash memories), an erase should be performed after following 16 consecutive writes inside the same page. Note that the erase operation then erases the entire sector.

**Remark:** Once a page has been written to 16 times, it is still possible to write to other pages within the same sector without performing a sector erase (assuming that those pages have been erased previously).

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 353. ISP Copy command

Command	С
Input	Flash Address(DST): Destination flash address where data bytes are to be written. The destination address should be a 256 byte boundary.
	RAM Address(SRC): Source RAM address from where data bytes are to be read.
	<b>Number of Bytes:</b> Number of bytes to be written. Should be 256   512   1024   4096.
Return Code	CMD_SUCCESS
	SRC_ADDR_ERROR (Address not on word boundary)
	DST_ADDR_ERROR (Address not on correct boundary)
	SRC_ADDR_NOT_MAPPED
	DST_ADDR_NOT_MAPPED
	COUNT_ERROR (Byte count is not 256   512   1024   4096)
	SECTOR_NOT_PREPARED_FOR WRITE_OPERATION
	BUSY
	CMD_LOCKED
	PARAM_ERROR
	CODE_READ_PROTECTION_ENABLED
Description	This command is used to program the flash memory. The "Prepare Sector(s) for Write Operation" command should precede this command. The affected sectors are automatically protected again once the copy command is successfully executed. The boot block cannot be written by this command. This command is blocked when code read protection is enabled. Also see <a href="Section 21.6">Section 21.6</a> for the number of bytes that can be written.
Example	"C 0 268467504 512 <cr><lf>" copies 512 bytes from the RAM address 0x1000 0800 to the flash address 0.</lf></cr>

#### 21.13.8 Go <address> <mode>

Table 354. ISP Go command

Command	G	
Input	<b>Address:</b> Flash or RAM address from which the code execution is to be started. This address should be on a word boundary.	
	<b>Mode:</b> T (Execute program in Thumb Mode)   A (Execute program in ARM mode).	
Return Code	CMD_SUCCESS	
	ADDR_ERROR	
	ADDR_NOT_MAPPED	
	CMD_LOCKED	
	PARAM_ERROR	
	CODE_READ_PROTECTION_ENABLED	
Description	This command is used to execute a program residing in RAM or flash memory. It may not be possible to return to the ISP command handler once this command is successfully executed. This command is blocked when code read protection is enabled.	
Example	"G 0 A <cr><lf>" branches to address 0x0000 0000 in ARM mode.</lf></cr>	

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.13.9 Erase sector(s) <start sector number> <end sector number>

Table 355. ISP Erase sector command

Command	E	
Input	Start Sector Number	
	End Sector Number: Should be greater than or equal to start sector number.	
Return Code	CMD_SUCCESS	
	BUSY	
	INVALID_SECTOR	
	SECTOR_NOT_PREPARED_FOR_WRITE_OPERATION	
	CMD_LOCKED	
	PARAM_ERROR	
	CODE_READ_PROTECTION_ENABLED	
Description	This command is used to erase one or more sector(s) of on-chip flash memory. The boot block can not be erased using this command. This command only allows erasure of all user sectors when the code read protection is enabled.	
Example	"E 2 3 <cr><lf>" erases the flash sectors 2 and 3.</lf></cr>	

## 21.13.10 Blank check sector(s) < sector number> < end sector number>

Table 356. ISP Blank check sector command

Command	I	
Input	Start Sector Number:	
	End Sector Number: Should be greater than or equal to start sector number.	
Return Code	CMD_SUCCESS	
	SECTOR_NOT_BLANK (followed by <offset blank="" first="" location="" non="" of="" the="" word=""> <contents blank="" location="" non="" of="" word="">)  </contents></offset>	
	INVALID_SECTOR	
	PARAM_ERROR	
Description	This command is used to blank check one or more sectors of on-chip flash memory.	
	Blank check on sector 0 always fails as first 64 bytes are re-mapped to flash boot block.	
	When CRP is enabled, the blank check command returns 0 for the offset and value of sectors which are not blank. Blank sectors are correctly reported irrespective of the CRP setting.	
Example	"I 2 3 <cr><lf>" blank checks the flash sectors 2 and 3.</lf></cr>	

#### 21.13.11 Read Part Identification number

Table 357. ISP Read Part Identification command

Command	J	
Input	None.	
Return Code	CMD_SUCCESS followed by part identification number in ASCII (see <u>Table 358</u> <u>"LPC1315/16/17/45/46/47 device identification numbers"</u> ).	
Description	This command is used to read the part identification number.	

**User manual** 

379 of 416

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 358. LPC1315/16/17/45/46/47 device identification numbers

Device	Hex coding
LPC1345FHN33	0x2801 0541
LPC1345FBD48	0x2801 0541
LPC1346FHN33	0x0801 8542
LPC1346FBD48	0x0801 8542
LPC1347FHN33	0x0802 0543
LPC1347FBD48	0x0802 0543
LPC1347FBD64	0x0802 0543
LPC1315FHN33	0x3A01 0523
LPC1315FBD48	0x3A01 0523
LPC1316FHN33	0x1A01 8524
LPC1316FBD48	0x1A01 8524
LPC1317FHN33	0x1A02 0525
LPC1317FBD48	0x1A02 0525
LPC1317FBD64	0x1A02 0525

#### 21.13.12 Read Boot code version number

Table 359. ISP Read Boot Code version number command

Command	К	
Input	None	
Return Code	e CMD_SUCCESS followed by 2 bytes of boot code version number in ASCII format. It is to be interpreted as <byte1(major)>.<byte0(minor)>.</byte0(minor)></byte1(major)>	
Description	This command is used to read the boot code version number.	

## 21.13.13 Compare <address1> <address2> <no of bytes>

Table 360. ISP Compare command

Command	M
Input	<b>Address1 (DST):</b> Starting flash or RAM address of data bytes to be compared. This address should be a word boundary.
	Address2 (SRC): Starting flash or RAM address of data bytes to be compared. This address should be a word boundary.
	<b>Number of Bytes:</b> Number of bytes to be compared; should be a multiple of 4.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 360. ISP Compare command

Command	M	
Return Code	CMD_SUCCESS   (Source and destination data are equal)	
	COMPARE_ERROR   (Followed by the offset of first mismatch)	
	COUNT_ERROR (Byte count is not a multiple of 4)	
	ADDR_ERROR	
	ADDR_NOT_MAPPED	
	PARAM_ERROR	
Description	This command is used to compare the memory contents at two locations.	
	Compare result may not be correct when source or destination address contains any of the first 512 bytes starting from address zero. First 512 bytes are re-mapped to boot ROM	
Example	"M 8192 268468224 4 <cr><lf>" compares 4 bytes from the RAM address 0x1000 8000 to the 4 bytes from the flash address 0x2000.</lf></cr>	

#### 21.13.14 ReadUID

Table 361. ReadUID command

Command	N	
Input	None	
Return Code	code CMD_SUCCESS followed by four 32-bit words of a unique serial number in ASCII format. The word sent at the lowest address is sent first.	
Description	This command is used to read the unique ID.	

## 21.13.15 ISP Return Codes

Table 362. ISP Return Codes Summary

Return Code	Mnemonic	Description	
0	CMD_SUCCESS	Command is executed successfully. Sent by ISP handler only when command given by the host has been completely and successfully executed.	
1	INVALID_COMMAND	Invalid command.	
2	SRC_ADDR_ERROR	Source address is not on word boundary.	
3	DST_ADDR_ERROR	Destination address is not on a correct boundary.	
4	SRC_ADDR_NOT_MAPPED	Source address is not mapped in the memory map. Count value is taken in to consideration where applicable.	
5	DST_ADDR_NOT_MAPPED	Destination address is not mapped in the memory map. Count value is taken in to consideration where applicable.	
6	COUNT_ERROR	Byte count is not multiple of 4 or is not a permitted value.	
7	INVALID_SECTOR	Sector number is invalid or end sector number is greater than start sector number.	
8	SECTOR_NOT_BLANK	Sector is not blank.	
9	SECTOR_NOT_PREPARED_FOR_ WRITE_OPERATION	Command to prepare sector for write operation was not executed.	

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 362. ISP Return Codes Summary

Return Code	Mnemonic	Description
10	COMPARE_ERROR	Source and destination data not equal.
11	BUSY	Flash programming hardware interface is busy.
12	PARAM_ERROR	Insufficient number of parameters or invalid parameter.
13	ADDR_ERROR	Address is not on word boundary.
14	ADDR_NOT_MAPPED	Address is not mapped in the memory map. Count value is taken in to consideration where applicable.
15	CMD_LOCKED	Command is locked.
16	INVALID_CODE	Unlock code is invalid.
17	INVALID_BAUD_RATE	Invalid baud rate setting.
18	INVALID_STOP_BIT	Invalid stop bit setting.
19	CODE_READ_PROTECTION_ ENABLED	Code read protection enabled.

#### 21.14 IAP commands

For in application programming the IAP routine should be called with a word pointer in register r0 pointing to memory (RAM) containing command code and parameters. Result of the IAP command is returned in the result table pointed to by register r1. The user can reuse the command table for result by passing the same pointer in registers r0 and r1. The parameter table should be big enough to hold all the results in case the number of results are more than number of parameters. Parameter passing is illustrated in the <a href="Figure 63">Figure 63</a>. The number of parameters and results vary according to the IAP command. The maximum number of parameters is 5, passed to the "Copy RAM to FLASH" command. The maximum number of results is 4, returned by the "ReadUID" command. The command handler sends the status code INVALID\_COMMAND when an undefined command is received. The IAP routine resides at 0x1FFF 1FF0 location and it is thumb code.

The IAP function could be called in the following way using C.

Define the IAP location entry point. Since the 0th bit of the IAP location is set there will be a change to Thumb instruction set when the program counter branches to this address.

```
#define IAP_LOCATION 0x1fff1ff1
```

Define data structure or pointers to pass IAP command table and result table to the IAP function:

```
unsigned long command[5];
unsigned long result[4];

or

unsigned long * command;
unsigned long * result;
command=(unsigned long *) 0x...
result= (unsigned long *) 0x...
```

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Define pointer to function type, which takes two parameters and returns void. Note the IAP returns the result with the base address of the table residing in R1.

```
typedef void (*IAP)(unsigned int [],unsigned int[]);
IAP iap_entry;
```

#### Setting function pointer:

```
iap_entry=(IAP) IAP_LOCATION;
```

Whenever you wish to call IAP you could use the following statement.

```
iap_entry (command, result);
```

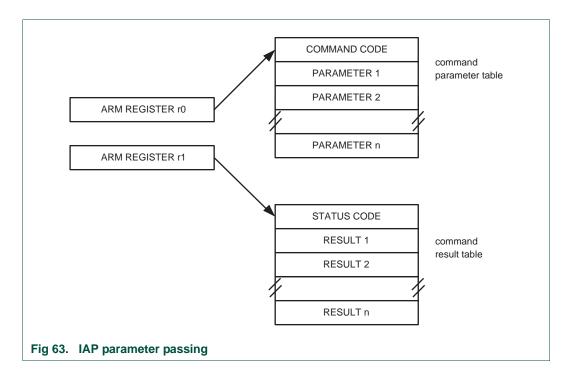

As per the ARM specification (The ARM Thumb Procedure Call Standard SWS ESPC 0002 A-05) up to 4 parameters can be passed in the r0, r1, r2 and r3 registers respectively. Additional parameters are passed on the stack. Up to 4 parameters can be returned in the r0, r1, r2 and r3 registers respectively. Additional parameters are returned indirectly via memory. Some of the IAP calls require more than 4 parameters. If the ARM suggested scheme is used for the parameter passing/returning then it might create problems due to difference in the C compiler implementation from different vendors. The suggested parameter passing scheme reduces such risk.

The flash memory is not accessible during a write or erase operation. IAP commands, which results in a flash write/erase operation, use 32 bytes of space in the top portion of the on-chip RAM for execution. The user program should not be use this space if IAP flash programming is permitted in the application.

**Table 363. IAP Command Summary** 

IAP Command	Command Code	Described in
Prepare sector(s) for write operation	50 (decimal)	<u>Table 364</u>
Copy RAM to flash	51 (decimal)	Table 365
Erase sector(s)	52 (decimal)	Table 366
Blank check sector(s)	53 (decimal)	Table 367
Read Part ID	54 (decimal)	Table 368
Read Boot code version	55 (decimal)	Table 369
Compare	56 (decimal)	Table 370
Reinvoke ISP	57 (decimal)	Table 371
Read UID	58 (decimal)	Table 372
Erase page	59 (decimal)	Table 373
EEPROM Write	61(decimal)	Table 374
EEPROM Read	62(decimal)	Table 375

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

## 21.14.1 Prepare sector(s) for write operation

This command makes flash write/erase operation a two step process.

Table 364. IAP Prepare sector(s) for write operation command

Prepare sector(s) for write operation	
Command code: 50 (decimal)	
Param0: Start Sector Number	
<b>Param1:</b> End Sector Number (should be greater than or equal to start sector number).	
CMD_SUCCESS	
BUSY	
INVALID_SECTOR	
None	
This command must be executed before executing "Copy RAM to flash" or "Erase Sector(s)" command. Successful execution of the "Copy RAM to flash" or "Erase Sector(s)" command causes relevant sectors to be protected again. The boot sector can not be prepared by this command. To prepare a single sector use the same "Start" and "End" sector numbers.	

## 21.14.2 Copy RAM to flash

See Section 21.13.7 for limitations on the write-to-flash process.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 365. IAP Copy RAM to flash command

Command	Copy RAM to flash
Input	Command code: 51 (decimal)
	<b>Param0(DST):</b> Destination flash address where data bytes are to be written. This address should be a 256 byte boundary.
	<b>Param1(SRC):</b> Source RAM address from which data bytes are to be read. This address should be a word boundary.
	Param2: Number of bytes to be written. Should be 256   512   1024   4096.
	Param3: System Clock Frequency (CCLK) in kHz.
Return Code	CMD_SUCCESS
	SRC_ADDR_ERROR (Address not a word boundary)
	DST_ADDR_ERROR (Address not on correct boundary)
	SRC_ADDR_NOT_MAPPED
	DST_ADDR_NOT_MAPPED
	COUNT_ERROR (Byte count is not 256   512   1024   4096)
	SECTOR_NOT_PREPARED_FOR_WRITE_OPERATION
	BUSY
Result	None
Description	This command is used to program the flash memory. The affected sectors should be prepared first by calling "Prepare Sector for Write Operation" command. The affected sectors are automatically protected again once the copy command is successfully executed. The boot sector can not be written by this command. Also see <a href="Section 21.6">Section 21.6</a> for the number of bytes that can be written.

## 21.14.3 Erase Sector(s)

Table 366. IAP Erase Sector(s) command

Erase Sector(s)	
Command code: 52 (decimal)	
Param0: Start Sector Number	
<b>Param1:</b> End Sector Number (should be greater than or equal to start sector number).	
Param2: System Clock Frequency (CCLK) in kHz.	
CMD_SUCCESS	
BUSY	
SECTOR_NOT_PREPARED_FOR_WRITE_OPERATION	
INVALID_SECTOR	
None	
This command is used to erase a sector or multiple sectors of on-chip flash memory. The boot sector can not be erased by this command. To erase a single sector use the same "Start" and "End" sector numbers.	

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

## 21.14.4 Blank check sector(s)

Table 367. IAP Blank check sector(s) command

Command	Blank check sector(s)	
Input	Command code: 53 (decimal)	
	Param0: Start Sector Number	
	<b>Param1:</b> End Sector Number (should be greater than or equal to start sector number).	
Return Code	CMD_SUCCESS	
	BUSY	
	SECTOR_NOT_BLANK	
	INVALID_SECTOR	
Result	<b>Result0:</b> Offset of the first non blank word location if the Status Code is SECTOR_NOT_BLANK.	
	Result1: Contents of non blank word location.	
Description	This command is used to blank check a sector or multiple sectors of on-chip flash memory. To blank check a single sector use the same "Start" and "End" sector numbers.	

#### 21.14.5 Read Part Identification number

Table 368. IAP Read Part Identification command

Read part identification number	
Command code: 54 (decimal)	
Parameters: None	
CMD_SUCCESS	
Result0: Part Identification Number.	
This command is used to read the part identification number.	

#### 21.14.6 Read Boot code version number

Table 369. IAP Read Boot Code version number command

Command	Read boot code version number
Input	Command code: 55 (decimal)
	Parameters: None
Return Code	CMD_SUCCESS
Result	Result0: 2 bytes of boot code version number. Read as  byte1(Major)>. byte0(Minor)>
Description	This command is used to read the boot code version number.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

## 21.14.7 Compare <address1> <address2> <no of bytes>

Table 370. IAP Compare command

Command	Compare		
Input	Command code: 56 (decimal)		
	<b>Param0(DST):</b> Starting flash or RAM address of data bytes to be compared. This address should be a word boundary.		
	<b>Param1(SRC):</b> Starting flash or RAM address of data bytes to be compared. This address should be a word boundary.		
	Param2: Number of bytes to be compared; should be a multiple of 4.		
Return Code	CMD_SUCCESS		
	COMPARE_ERROR		
	COUNT_ERROR (Byte count is not a multiple of 4)		
	ADDR_ERROR		
	ADDR_NOT_MAPPED		
Result	Result0: Offset of the first mismatch if the Status Code is COMPARE_ERROR.		
Description	This command is used to compare the memory contents at two locations.		
	The result may not be correct when the source or destination includes any of the first 512 bytes starting from address zero. The first 512 bytes can be re-mapped to RAM.		

#### 21.14.8 Reinvoke ISP

Table 371. Reinvoke ISP

Command	Compare
Input	Command code: 57 (decimal)
Return Code	None
Result	None.
Description	This command is used to invoke the bootloader in ISP mode. It maps boot vectors, sets PCLK = CCLK, configures UART pins RXD and TXD, resets counter/timer CT32B1 and resets the FDR register (see <u>Table 221</u> ). This command may be used when a valid user program is present in the internal flash memory and the PIOO_1 pin is not accessible to force the ISP mode.

#### 21.14.9 ReadUID

Table 372. IAP ReadUID command

Command	Compare			
Input	Command code: 58 (decimal)			
Return Code	CMD_SUCCESS			
Result	Result0: The first 32-bit word (at the lowest address). Result1: The second 32-bit word. Result2: The third 32-bit word. Result3: The fourth 32-bit word.			
Description	This command is used to read the unique ID.			

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

## 21.14.10 Erase page

Table 373. IAP Erase page command

Command	Erase page		
Input	Command code: 59 (decimal)		
	Param0: Start page number.		
	Param1: End page number (should be greater than or equal to start page)		
	Param2: System Clock Frequency (CCLK) in kHz.		
Return Code	CMD_SUCCESS		
	BUSY		
	SECTOR_NOT_PREPARED_FOR_WRITE_OPERATION		
	INVALID_SECTOR		
Result	None		
Description	This command is used to erase a page or multiple pages of on-chip flash memory. To erase a single page use the same "start" and "end" page numbers.		

#### **21.14.11 Write EEPROM**

Table 374. IAP Write EEPROM command

Command	Compare
Input	Command code: 61 (decimal) Param0: EEPROM address. Param1: RAM address. Param2: Number of bytes to be written. Param3: System Clock Frequency (CCLK) in kHz.
Return Code	CMD_SUCCESS   SRC_ADDR_NOT_MAPPED   DST_ADDR_NOT_MAPPED
Result	None
Description	Data is copied from the RAM address to the EEPROM address.
	<b>Remark:</b> The top 64 bytes of the EEPROM memory are reserved and cannot be written to.

#### 21.14.12 Read EEPROM

Table 375. IAP Read EEPROM command

Command	Compare
Input	Command code: 62 (decimal) Param0: EEPROM address. Param1: RAM address. Param2: Number of bytes to be read. Param3: System Clock Frequency (CCLK) in kHz.
Return Code	CMD_SUCCESS   SRC_ADDR_NOT_MAPPED   DST_ADDR_NOT_MAPPED
Result	None
Description	Data is copied from the EEPROM address to the RAM address.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

#### 21.14.13 IAP Status Codes

Table 376. IAP Status Codes Summary

Status Code	Mnemonic	Description
0	CMD_SUCCESS	Command is executed successfully.
1	INVALID_COMMAND	Invalid command.
2	SRC_ADDR_ERROR	Source address is not on a word boundary.
3	DST_ADDR_ERROR	Destination address is not on a correct boundary.
4	SRC_ADDR_NOT_MAPPED	Source address is not mapped in the memory map. Count value is taken in to consideration where applicable.
5	DST_ADDR_NOT_MAPPED	Destination address is not mapped in the memory map. Count value is taken in to consideration where applicable.
6	COUNT_ERROR	Byte count is not multiple of 4 or is not a permitted value.
7	INVALID_SECTOR	Sector number is invalid.
8	SECTOR_NOT_BLANK	Sector is not blank.
9	SECTOR_NOT_PREPARED_ FOR_WRITE_OPERATION	Command to prepare sector for write operation was not executed.
10	COMPARE_ERROR	Source and destination data is not same.
11	BUSY	flash programming hardware interface is busy.

## 21.15 Debug notes

#### 21.15.1 Comparing flash images

Depending on the debugger used and the IDE debug settings, the memory that is visible when the debugger connects might be the boot ROM, the internal SRAM, or the flash. To help determine which memory is present in the current debug environment, check the value contained at flash address 0x0000 0004. This address contains the entry point to the code in the ARM Cortex-M3 vector table, which is the bottom of the boot ROM, the internal SRAM, or the flash memory respectively.

Table 377. Memory mapping in debug mode

Memory mapping mode	Memory start address visible at 0x0000 0004		
Bootloader mode	0x1FFF 0000		
User flash mode	0x0000 0000		
User SRAM mode	0x1000 0000		

## 21.15.2 Serial Wire Debug (SWD) flash programming interface

Debug tools can write parts of the flash image to RAM and then execute the IAP call "Copy RAM to flash" repeatedly with proper offset.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

## 21.16 Flash controller registers

Table 378. Register overview: FMC (base address 0x4003 C000)

	_				
Name	Access	Address offset	Description	Reset value	Reference
FLASHCFG	R/W	0x010	Flash memory access time configuration register	-	<u>Table 379</u>
FMSSTART	R/W	0x020	Signature start address register	0	Table 380
FMSSTOP	R/W	0x024	Signature stop-address register	0	Table 381
FMSW0	R	0x02C	Word 0 [31:0]	-	Table 382
FMSW1	R	0x030	Word 1 [63:32]	-	Table 383
FMSW2	R	0x034	Word 2 [95:64]	-	Table 384
FMSW3	R	0x038	Word 3 [127:96]	-	Table 385
FMSTAT	R	0xFE0	Signature generation status register	0	Section 21. 16.5
FMSTATCLR	W	0xFE8	Signature generation status clear register	-	Section 21. 16.6

#### 21.16.1 Flash memory access register

Depending on the system clock frequency, access to the flash memory can be configured with various access times by writing to the FLASHCFG register.

**Remark:** Improper setting of this register may result in incorrect operation of the LPC1315/16/17/45/46/47 flash memory. Do not change the flash access time when using the power profiles in efficiency, performance, or low-current modes.

Table 379. Flash configuration register (FLASHCFG, address 0x4003 C010) bit description

Bit	Symbol	Value	Description	Reset value
1:0	FLASHTIM		Flash memory access time. FLASHTIM +1 is equal to the number of system clocks used for flash access.	0x2
		0x0	1 system clock flash access time (for system clock frequencies of up to 25 MHz).	
		0x1	2 system clocks flash access time (for system clock frequencies of up to 55 MHz).	
		0x2	3 system clocks flash access time (for system clock frequencies of up to 72 MHz).	
		0x3	Reserved.	
31:2	-	-	Reserved. User software must not change the value of these bits. Bits 31:2 must be written back exactly as read.	-

#### 21.16.2 Flash signature generation

The flash module contains a built-in signature generator. This generator can produce a 128-bit signature from a range of flash memory. A typical usage is to verify the flashed contents against a calculated signature (e.g. during programming).

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

The address range for generating a signature must be aligned on flash-word boundaries, i.e. 128-bit boundaries. Once started, signature generation completes independently. While signature generation is in progress, the flash memory cannot be accessed for other purposes, and an attempted read will cause a wait state to be asserted until signature generation is complete. Code outside of the flash (e.g. internal RAM) can be executed during signature generation. This can include interrupt services, if the interrupt vector table is re-mapped to memory other than the flash memory. The code that initiates signature generation should also be placed outside of the flash memory.

#### 21.16.3 Signature generation address and control registers

These registers control automatic signature generation. A signature can be generated for any part of the flash memory contents. The address range to be used for generation is defined by writing the start address to the signature start address register (FMSSTART) and the stop address to the signature stop address register (FMSSTOP). The start and stop addresses must be aligned to 128-bit boundaries and can be derived by dividing the byte address by 16.

Signature generation is started by setting the SIG\_START bit in the FMSSTOP register. Setting the SIG\_START bit is typically combined with the signature stop address in a single write.

<u>Table 380</u> and <u>Table 381</u> show the bit assignments in the FMSSTART and FMSSTOP registers respectively.

Table 380. Flash module signature start register (FMSSTART - 0x4003 C020) bit description

Bit	Symbol	Description	Reset value
16:0	START	Signature generation start address (corresponds to AHB byte address bits[20:4]).	0
31:17	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

Table 381. Flash module signature stop register (FMSSTOP - 0x4003 C024) bit description

Bit	Symbol	Value	Description	Reset value
16:0	STOP		BIST stop address divided by 16 (corresponds to AHB byte address [20:4]).	0
17	SIG_START		Start control bit for signature generation.	0
		0	Signature generation is stopped	
		1	Initiate signature generation	
31:18	-		Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 21.16.4 Signature generation result registers

The signature generation result registers return the flash signature produced by the embedded signature generator. The 128-bit signature is reflected by the four registers FMSW0, FMSW1, FMSW2 and FMSW3.

391 of 416

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

The generated flash signature can be used to verify the flash memory contents. The generated signature can be compared with an expected signature and thus makes saves time and code space. The method for generating the signature is described in Section 21.16.2.

<u>Table 385</u> show bit assignment of the FMSW0 and FMSW1, FMSW2, FMSW3 registers respectively.

Table 382. FMSW0 register (FMSW0, address: 0x4003 C02C) bit description

Bit	Symbol	Description	Reset value
31:0	SW0[31:0]	Word 0 of 128-bit signature (bits 31 to 0).	-

Table 383. FMSW1 register (FMSW1, address: 0x4003 C030) bit description

Bit	Symbol	Description	Reset value
31:0	SW1[63:32]	Word 1 of 128-bit signature (bits 63 to 32).	-

Table 384. FMSW2 register (FMSW2, address: 0x4003 C034) bit description

Bit	Symbol	Description	Reset value
31:0	SW2[95:64]	Word 2 of 128-bit signature (bits 95 to 64).	-

Table 385. FMSW3 register (FMSW3, address: 0x4003 40C8) bit description

Bit	Symbol	Description	Reset value
31:0	SW3[127:96]	Word 3 of 128-bit signature (bits 127 to 96).	-

#### 21.16.5 Flash module status register

The read-only FMSTAT register provides a means of determining when signature generation has completed. Completion of signature generation can be checked by polling the SIG\_DONE bit in FMSTAT register. SIG\_DONE should be cleared via the FMSTATCLR register before starting a signature generation operation, otherwise the status might indicate completion of a previous operation.

Table 386. Flash module status register (FMSTAT - 0x4003 CFE0) bit description

Bit	Symbol	Description	Reset value
1:0	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
2	SIG_DONE	When 1, a previously started signature generation has completed. See FMSTATCLR register description for clearing this flag.	0
31:3	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 21.16.6 Flash module status clear register

The FMSTATCLR register is used to clear the signature generation completion flag.

#### Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming

Table 387. Flash module status clear register (FMSTATCLR - 0x0x4003 CFE8) bit description

Bit	Symbol	Description	Reset value
1:0	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA
2	SIG_DONE_CLR	Writing a 1 to this bits clears the signature generation completion flag (SIG_DONE) in the FMSTAT register.	0
31:3	-	Reserved, user software should not write ones to reserved bits. The value read from a reserved bit is not defined.	NA

#### 21.16.7 Algorithm and procedure for signature generation

#### Signature generation

A signature can be generated for any part of the flash contents. The address range to be used for signature generation is defined by writing the start address to the FMSSTART register, and the stop address to the FMSSTOP register.

The signature generation is started by writing a '1' to the SIG\_START bit in the FMSSTOP register. Starting the signature generation is typically combined with defining the stop address, which is done in the STOP bits of the same register.

The time that the signature generation takes is proportional to the address range for which the signature is generated. Reading of the flash memory for signature generation uses a self-timed read mechanism and does not depend on any configurable timing settings for the flash. A safe estimation for the duration of the signature generation is:

When signature generation is triggered via software, the duration is in AHB clock cycles, and tcy is the time in ns for one AHB clock. The SIG\_DONE bit in FMSTAT can be polled by software to determine when signature generation is complete.

After signature generation, a 128-bit signature can be read from the FMSW0 to FMSW3 registers. The 128-bit signature reflects the corrected data read from the flash. The 128-bit signature reflects flash parity bits and check bit values.

#### Content verification

The signature as it is read from the FMSW0 to FMSW3 registers must be equal to the reference signature. The algorithms to derive the reference signature is given in Figure 64.

# **Chapter 22: LPC1315/16/17/45/46/47 Serial Wire Debugger (SWD)**

Rev. 4 — 12 March 2013

**User manual** 

## 22.1 How to read this chapter

The debug functionality is identical for all LPC1315/16/17/45/46/47 parts.

#### 22.2 Features

- Supports ARM Serial Wire Debug mode.
- Trace port provides CPU instruction trace capability. Output via a Serial Wire Viewer.
- Direct debug access to all memories, registers, and peripherals.
- No target resources are required for the debugging session.
- Four breakpoints. Four instruction breakpoints that can also be used to remap instruction addresses for code patches. Two data comparators that can be used to remap addresses for patches to literal values.
- Two data watchpoints that can also be used as triggers.
- Supports JTAG boundary scan.
- Instrumentation Trace Macrocell allows additional software controlled trace.

#### 22.3 Introduction

Debug functions are integrated into the ARM Cortex-M3. Serial wire debug functions are supported. The ARM Cortex-M3 is configured to support up to four breakpoints and two watchpoints.

## 22.4 Description

Debugging with the LPC1315/16/17/45/46/47 uses the Serial Wire Debug mode. Support for boundary scan is available.

Trace is supported via the Serial Wire Output.

## 22.5 Pin description

The tables below indicate the various pin functions related to debug. Some of these functions share pins with other functions which therefore may not be used at the same time. Trace using the Serial Wire Output has limited bandwidth.

#### Chapter 22: LPC1315/16/17/45/46/47 Serial Wire Debugger (SWD)

Table 388. Serial Wire Debug pin description

Pin Name	Туре	Description
SWCLK	Input	<b>Serial Wire Clock.</b> This pin is the clock for SWD debug logic when in the Serial Wire Debug mode (SWD). This pin is pulled up internally.
SWDIO	Input / Output	<b>Serial wire debug data input/output.</b> The SWDIO pin is used by an external debug tool to communicate with and control the LPC1315/16/17/45/46/47. This pin is pulled up internally.
SWO	Output	<b>Serial Wire Output.</b> The SWO pin optionally provides data from the ITM and/or the ETM for an external debug tool to evaluate.

#### Table 389. JTAG boundary scan pin description

Pin Name	Туре	Description
TCK	Input	<b>JTAG Test Clock</b> . This pin is the clock for JTAG boundary scan when the RESET pin is LOW.
TMS	Input	<b>JTAG Test Mode Select.</b> The TMS pin selects the next state in the TAP state machine. This pin includes an internal pull-up and is used for JTAG boundary scan when the RESET pin is LOW.
TDI	Input	<b>JTAG Test Data In.</b> This is the serial data input for the shift register. This pin includes an internal pull-up and is used for JTAG boundary scan when the RESET pin is LOW.
TDO	Output	JTAG Test Data Output. This is the serial data output from the shift register. Data is shifted out of the device on the negative edge of the TCK signal. This pin is used for JTAG boundary scan when the RESET pin is LOW.
TRST	Input	<b>JTAG Test Reset.</b> The TRST pin can be used to reset the test logic within the debug logic. This pin includes an internal pull-up and is used for JTAG boundary scan when the RESET pin is LOW.

## 22.6 Functional description

#### 22.6.1 Debug limitations

**Important:** Due to limitations of the ARM Cortex-M3 integration, the LPC1315/16/17/45/46/47 cannot wake up in the usual manner from Deep-sleep mode. It is recommended not to use this mode during debug.

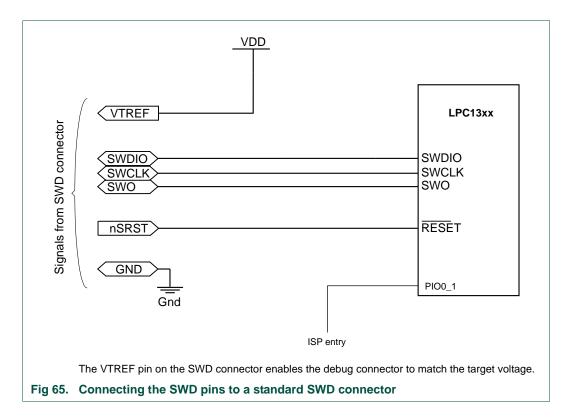

Another issue is that debug mode changes the way in which reduced power modes work internal to the ARM Cortex-M3 CPU, and this ripples through the entire system. These differences mean that power measurements should not be made while debugging, the results will be higher than during normal operation in an application.

During a debugging session, the System Tick Timer is automatically stopped whenever the CPU is stopped. Other peripherals are not affected.

## 22.6.2 Debug connections for SWD

For debugging purposes, it is useful to provide access to the ISP entry pin PIO0\_1. This pin can be used to recover the part from configurations which would disable the SWD port such as improper PLL configuration, reconfiguration of SWD pins as ADC inputs, entry into Deep power-down mode out of reset, etc. This pin can be used for other functions such as GPIO, but it should not be held LOW on power-up or reset.

#### Chapter 22: LPC1315/16/17/45/46/47 Serial Wire Debugger (SWD)

#### 22.6.3 Boundary scan

The RESET pin selects between the test TAP controller for JTAG boundary scan (RESET = LOW) and the ARM SWD debug port TAP controller (RESET = HIGH). The ARM SWD debug port is disabled while the LPC1315/16/17/45/46/47 is in reset. A LOW on the TRST pin resets the test TAP controller.

**Remark:** Boundary scan operations should not be started until 250  $\mu$ s after POR. The test TAP must be reset after the boundary scan and left in either TLR or RTO state. Boundary scan is not affected by Code Read Protection.

**Remark:** POR, BOD reset, or a LOW on the TRST pin puts the test TAP controller in the Test-Logic Reset state. The first TCK clock while RESET = HIGH places the test TAP in Run-Test Idle mode.

# Chapter 21: LPC1315/16/17/45/46/47 Flash/EEPRPOM programming firmware

21.1	How to read this chapter	364	21.13.10	Blank check sector(s) <sector number=""> <end< th=""><th></th></end<></sector>	
21.2	Bootloader	364		sector number>	379
21.3	Features	364	21.13.11		379
21.4	Description				380
21.5	Memory map after any reset		21.13.13	Compare <address1> <address2></address2></address1>	
_			04.40.44	<no bytes="" of=""></no>	
21.6	Flash content protection mechanism			ReadUID	
21.7	Criterion for Valid User Code			ISP Return Codes	
21.8	ISP/IAP communication protocol			AP commands	
21.8.1	ISP command format		21.14.1	Prepare sector(s) for write operation	
21.8.2	ISP response format		21.14.2	, ,	384
21.8.3	ISP data format		21.14.3	. ,	385
21.8.4	ISP flow control		21.14.4	( )	386
21.8.5	ISP command abort		21.14.5		386
21.8.6	Interrupts during ISP		21.14.6		386
21.8.7	Interrupts during IAP	368	21.14.7	Compare <address1> <address2></address2></address1>	207
21.8.8	RAM used by ISP command handler		24 4 4 0	<no bytes="" of=""></no>	
21.8.9	RAM used by IAP command handler		21.14.8 21.14.9	Reinvoke ISP	
21.9	USB communication protocol		21.14.9	Erase page	
21.9.1	Usage note	369	21.14.10	Write EEPROM	
21.10	Boot process flowchart	370		Read EEPROM	
21.11	Sector numbers	371		IAP Status Codes	
21.12	Code Read Protection (CRP)	371		Debug notes	
21.12.1	ISP entry protection		21.15.1		389
21.13	ISP commands		21.15.1	Serial Wire Debug (SWD) flash programming	503
21.13.1	Unlock <unlock code=""></unlock>		21.10.2	interface	389
21.13.2	Set Baud Rate <baud rate=""> <stop bit=""></stop></baud>		21.16 F		<b>390</b>
21.13.3	Echo <setting></setting>		21.16.1	<del>-</del>	390
21.13.4	Write to RAM <start address=""></start>		21.16.1	, ,	390
	<number bytes="" of=""></number>	375	21.16.3	Signature generation address and control	390
21.13.5	Read Memory <address> <no. bytes="" of=""></no.></address>		21.10.5		391
21.13.6	Prepare sector(s) for write operation <start se<="" td=""><td></td><td>21.16.4</td><td>•</td><td>391</td></start>		21.16.4	•	391
	number> <end number="" sector=""></end>		21.16.5		392
21.13.7	Copy RAM to flash <flash address=""> <ram< td=""><td></td><td>21.16.6</td><td></td><td>392</td></ram<></flash>		21.16.6		392
	address> <no bytes="" of=""></no>	377	21.16.7	Algorithm and procedure for signature	002
21.13.8	Go <address> <mode></mode></address>		21.10.7	generation	393
21.13.9	Erase sector(s) <start number="" sector=""> <end< td=""><td></td><td></td><td>Signature generation</td><td></td></end<></start>			Signature generation	
	sector number>	379		Content verification	
Chapt	er 22: LPC1315/16/17/45/46/47 Serial	Wire D	Debugge		
22.1	How to read this chapter			· · · ·	396
22.2	Features		22.6.1	•	396
