39.6.21 South Core Gpio Level 4 (cfio_ioreg_SC_GP_LVL_127_96_)—Offset 68h

This registers are implemented as dual read/write with dedicated storage for write. Write value will be stored in the write register, while read is coming from the pad directly. If GPIO(n) is programmed to be an output (via the corresponding bit in the

GP_IO_SEL register), then the corresponding GP_LVL(n) write register value will drive a high or low value on the output pin. 1 = high, 0 = low. - Only the 8 lsb are used in VLV

39.6.22 South Core Trigger Positive Edge Enable 4 (cfio_ioreg_SC_TPE_127_96_)—Offset 6Ch

Access via PCU proxy, the register trigger Positive Edge Enable: When set to a 1, the corresponding GPIO signal (if enabled in the GPIO_USE_SEL register) will case an GPE or SMI when a 0 to 1 transition occurs. When set to 0, the GPIO signal is not enabled to trigger an GPE or SMI on a 0 to 1 transition. - Only the 8 lsb are used in VLV

39.6.24 South Core Trigger Status 4 (cfio_ioreg_SC_TS_127_96_)—Offset 74h

When set to a 1, the corresponding GPIO (if enabled in the GPIO_USE_SEL register) if enabled as input via IO_SEL(n), triggered an GPE or SMI. This will be set if a 0 to 1 transition occurred and TPE(n) was set, or a 1 to 0 transition occurred and TNE(n) was set. If both TPE(n) and TNE(n) are set, then this bit will be set on both a 0 to 1 and a 1 to 0 transition. This bit will not be set if the GPIO is configured as an output. - Only the 8 lsb are used in VLV

39.7.1 Uart1 Rts B Pad Configuration (cfio_regs_pad_uart1_rts_b_PCONF0)—Offset 0h

PADs Memory space configuration register (access via PCU proxy)

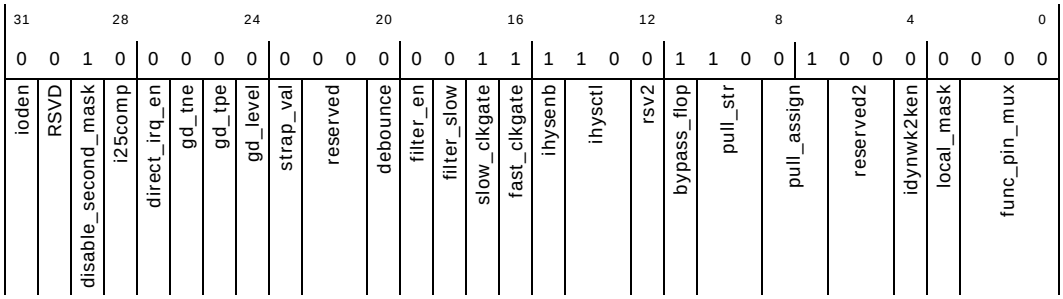
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

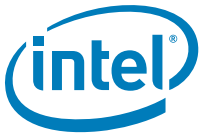
cfio_regs_pad_uart1_rts_b_PCONF0: [IOBASE] + 0h

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 2003CC80h



Bit Range	Default & Access	Description
31	0b RW	**Ioden (ioden):** Open Drain enable. Active high. Voltage domain: vcccore_1p0
30	0b RO	**Reserved (RSVD):** Reserved.



Bit Range	Default & Access	Description
29	1b RW	**Disable Second Mask (disable_second_mask):** This bit will disable second mask when PB_CONFIG all_func_mask is used. The second mask is for changing the pull and the direction of the pad in different cycles. Please refer to the GPIO HAS for details.
28	0b RO	**I25comp (i25comp):** 25 ohm compensation of hflvt buffers
27	0b RW	**Direct Irq En (direct_irq_en):** If this bit is set, interrupt will used direct wire and not shared. This bit should be cleared if io access mode is selected for this pad
26	0b RW	**Gd Tne (gd_tne):** Negative edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active low level irq
25	0b RW	**Gd Tpe (gd_tpe):** Positive edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active high level irq
24	0b RW	**Gd Level (gd_level):** When this bit is set a level irq will be choosed and not edge irq
23	0b RO	**Strap Val (strap_val):** If strap pin exist, this bit will reflect its value even if overriden with DFT value
22:21	0h RO	**Reserved (reserved):** reserved
20	0b RW	**Debounce (debounce):** Enabling the debouncer for this pad. Debounce time will be according to the community setting at the debouce control register
19	0b RW	**Filter En (filter_en):** Enabling the glitch filter
18	0b RW	**Filter Slow (filter_slow):** Use RTC clock for unglitch filter. This bit is reserved if unglitch filter does not exist for this pad
17	1b RW	**Slow Clkgate (slow_clkgate):** 1 Enables the glitch filter slow clock
16	1b RW	**Fast Clkgate (fast_clkgate):** 1 Enables the glitch filter fast clock
15	1b RO	**Ihysenb (ihysenb):** Hysteresis enable, active low
14:13	10b RW	**Ihysctl (ihysctl):** Hysteresis control
12	0b RO	**Rsv2 (rsv2):** reserved
11	1b RO	**Bypass Flop (bypass_flop):** 1 - Bypass pad controller I/O flops (if exists) 0 - Flop enabled if exists.
10:9	10b RW	**Pull Str (pull_str):** Pull strength: 00 - 2K 01 - 10K 10 - 20K 11 - 40K
8:7	01b RW	**Pull Assign (pull_assign):** Pull assignment: 00 - Non pull 01 - Pull Up 10 - Pull down 11 - reserved
6:5	00b RO	**Reserved2 (reserved2):** reserved
4	0b RW	**Idynwk2ken (idynwk2ken):** reduce weak 2kohm pull contention current when other chip driving
3	0b RO	**Local Mask (local_mask):** reserved

Bit Range	Default & Access	Description
2:0	000b RW	**Func Pin Mux (func_pin_mux):** Func_Pin_Mux: Functional Pin Muxing Default function is always 0. These 3 bits are setting the memory function. Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

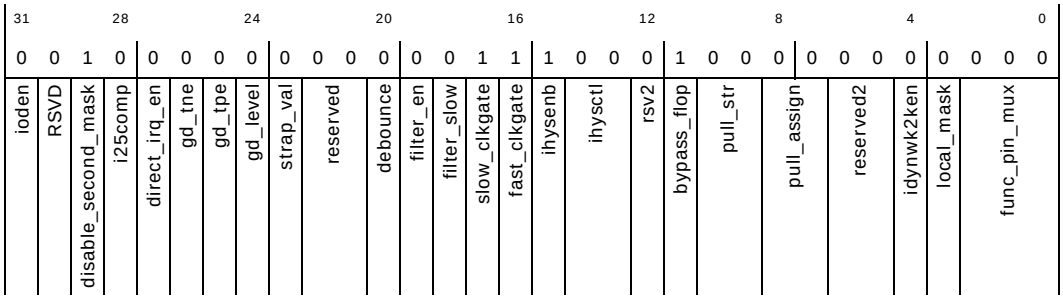
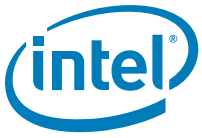
cfio_regs_pad_vgpio_3_PCONF0: [IOBASE] + 6E0h

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 20038800h





Bit Range	Default & Access	Description
31	0b RO	**Ioden (ioden):** Open Drain enable. Active high. Voltage domain: vcccore_1p0
30	0b RO	**Reserved (RSVD):** Reserved.
29	1b RW	**Disable Second Mask (disable_second_mask):** This bit will disable second mask when PB_CONFIG all_func_mask is used. The second mask is for changing the pull and the direction of the pad in different cycles. Please refer to the GPIO HAS for details.
28	0b RO	**I25comp (i25comp):** 25 ohm compensation of hflvt buffers
27	0b RW	**Direct Irq En (direct_irq_en):** If this bit is set, interrupt will used direct wire and not shared. This bit should be cleared if io access mode is selected for this pad
26	0b RW	**Gd Tne (gd_tne):** Negative edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active low level irq
25	0b RW	**Gd Tpe (gd_tpe):** Positive edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active high level irq
24	0b RW	**Gd Level (gd_level):** When this bit is set a level irq will be choosed and not edge irq
23	0b RO	**Strap Val (strap_val):** If strap pin exist, this bit will reflect its value even if overriden with DFT value
22:21	0h RO	**Reserved (reserved):** reserved
20	0b RO	**Debounce (debounce):** Enabling the debouncer for this pad. Debounce time will be according to the community setting at the debouce control register
19	0b RO	**Filter En (filter_en):** Enabling the glitch filter
18	0b RO	**Filter Slow (filter_slow):** Use RTC clock for unglitch filter. This bit is reserved if unglitch filter does not exist for this pad
17	1b RO	**Slow Clkgate (slow_clkgate):** 1 Enables the glitch filter slow clock
16	1b RO	**Fast Clkgate (fast_clkgate):** 1 Enables the glitch filter fast clock
15	1b RO	**Ihysenb (ihysenb):** Hysteresis enable, active low
14:13	00b RO	**Ihysctl (ihysctl):** Hysteresis control
12	0b RO	**Rsv2 (rsv2):** reserved
11	1b RO	**Bypass Flop (bypass_flop):** 1 - Bypass pad controller I/O flops (if exists) 0 - Flop enabled if exists.
10:9	00b RO	**Pull Str (pull_str):** Pull strength: 00 - 2K 01 - 10K 10 - 20K 11 - 40K
8:7	00b RO	**Pull Assign (pull_assign):** Pull assignment: 00 - Non pull 01 - Pull Up 10 - Pull down 11 - reserved
6:5	00b RO	**Reserved2 (reserved2):** reserved

Bit Range	Default & Access	Description
4	0b RO	**Idynwk2ken (idynwk2ken):** reduce weak 2kohm pull contention current when other chip driving
3	0b RO	**Local Mask (local_mask):** reserved
2:0	000b RW	**Func Pin Mux (func_pin_mux):** Func_Pin_Mux: Functional Pin Muxing Default function is always 0. These 3 bits are setting the memory function. The func_pin_mux function is masked by all_func_mask bit at the PB_CONFIG register. When IO_USE_SEL is set the pad will choose the GPIO function.

14:11	0000b RW	**Ircintsel (ircintsel):** Interval select this will select the periodic RCOMP update interval. All are periodic mode except 0000 option. 0000 non-periodic mode 0.5ms - 0001 1ms 0010 2ms 0011 3ms - 0100 4ms - 0101 5ms - 0110 10ms 0111 (Defaul) 15ms - 1000 25ms - 1001 50ms - 1010 100ms - 1011 200ms 1100 500ms - 1101 1000ms - 1110 2000ms - 1111 (non-periodic mode RCOMP update is not automatically triggered after the initial RCOMP cycle)
10	0b RW	**Ircforce (ircforce):** Force rcomp. only valid during non-periodic mode. RCOMP SM will trigger upon this signal goes high, so need first to clear it, and then set it high
9	0b RW	**Ircfreeze (ircfreeze):** Freeze rcomp. only valid during periodic mode. Setting this bit to 1 will stop the RCOMP S/M by stopping and clearing the 1ms and 10ms counter. Clearing it (0) would enable 1ms and 10ms counter again.
8:7	01b RW	**Ircstpcal (ircstpcal):** Stop calibration option. RCOMP SM (pullup and pulldown) will finish calibrating once orcpupen/orcpdnen toggle/s. The toggling would indicate the compensation value has been reached. This options is programmable for toggle once (single edge), toggle twice (double edge), toggle thrice (triple edge) or forcing it to finish after a certain cycle (defined by ircstpcyc input). 00 single edge detect (10 or 01) 01 double egde detect (101 or 010) (default) 10 triple edge detect (1010 or 0101) 11 stop after x cycles (depending on ircompstpcyc[3:0] value -- This is meant for debug) Default is 01 (double edge detect 101 or 010)
6:3	0000b RW	**Ircstpcyc (ircstpcyc):** Number of cycles calibration would be going through before stopping.0000 0 cycle 0001 1 cycle 0010 2 cycles ..... 1110 14 cycles 1111 15 cycles (maximum allowed with this options) valid only when ircompstpcal[1:0]=2b11. This is meant for debug.
2	0b RW	**Ircoen (ircoen):** Override enable. Setting this bit would allow system to go and override RCOMP value with data from config registers (which will drive ircpuov and ircpdov)
1	0b RW	**Ircoload (ircoload):** Do override now. only valid with ircoen enabled. once this bit is set, data from ircpuov and ircpdov will be loaded into each buffer

Bit Range	Default & Access	Description
0	0b RW	**Ircdfx Select (ircdfx_select):** Bypass RCOMP calibration values and use DFX values instead. Setting this bit (1) would let ircdfx_pstr and ircdfx_nstr value loaded into all buffers.

Default: 0003000Fh

Bit Range	Default & Access	Description
31:16	0003h RW	**Pstr (pstr):** positive strength - for cfiohvio buffers, only the 2 lsb bits will be used
15:0	000Fh RW	**Nstr (nstr):** negetive strength - for cfiohvio buffers, only the 3 lsb bits will be used

39.7.422 Ssp Strength Group (cfio_regs_ssp_STRENGTH)—Offset 894h

P and N strength register

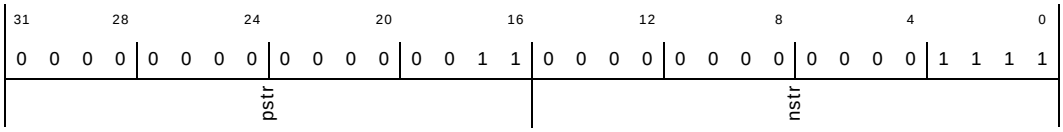
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

cfio_regs_ssp_STRENGTH: [IOBASE] + 894h

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 0003000Fh



Bit Range	Default & Access	Description
31:16	0003h RW	**Pstr (pstr):** positive strength - for cfiohvio buffers, only the 2 lsb bits will be used
15:0	000Fh RW	**Nstr (nstr):** negetive strength - for cfiohvio buffers, only the 3 lsb bits will be used

39.7.423 Uart1 Strength Group (cfio_regs_uart1_STRENGTH)—Offset 898h

P and N strength register

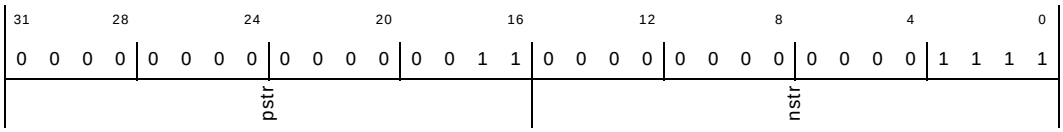
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

cfio_regs_uart1_STRENGTH: [IOBASE] + 898h

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 0003000Fh



Bit Range	Default & Access	Description
31:16	0003h RW	**Pstr (pstr):** positive strength - for cfiohvio buffers, only the 2 lsb bits will be used
15:0	000Fh RW	**Nstr (nstr):** negetive strength - for cfiohvio buffers, only the 3 lsb bits will be used

39.7.424 Aza1 Electrical Group (cfio_regs_aza1_ELECTRICAL)—Offset 89Ch

Electrical register includes slew and static values

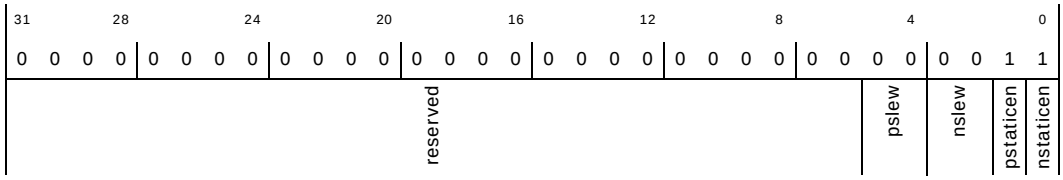
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

cfio_regs_aza1_ELECTRICAL: [IOBASE] + 89Ch

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 00000003h



Bit Range	Default & Access	Description
31:6	0000h RO	**Reserved (reserved):** reserved
5:4	00b RW	**Pslew (pslew):** positive slew rate - for cfiohvio buffers, only the lsb will be used

39.8.1 Sus Use Select 1 (cfio_ioreg_SUS_USE_SEL_31_0_)—Offset 0h

Access via PCU Proxy, the register is setting the correspanding GPIO to be selected and to be changed to IO access instead of the default Memory access. Bit 0 will set GPIO[0], and bit 1 will set GPIO[1] and so on. The default of IO GPIO pad is input so pull must be activated in the pad pconf0 register.

39.8.6 Sus Trigger Status 1 (cfio_ioreg_SUS_TS_31_0_)—Offset 14h

Access via PCU Proxy, When set to a 1, the corresponding GPIO (if enabled in the GPIO_USE_SEL register) if enabled as input via IO_SEL(n), triggered an GPE or SMI. This will be set if a 0 to 1 transition occurred and TPE(n) was set, or a 1 to 0 transition occurred and TNE(n) was set. If both TPE(n) and TNE(n) are set, then this bit will be set on both a 0 to 1 and a 1 to 0 transition. This bit will not be set if the GPIO is configured as an output. - Only the 8 lsb are used in VLV and it cannot be tested by the host

39.9.1 Usb Oc1 B Pad Configuration (cfio_regs_pad_usb_oc1_b_PCONF0)—Offset 0h

PADs Memory space configuration register (Access via PCU Proxy)

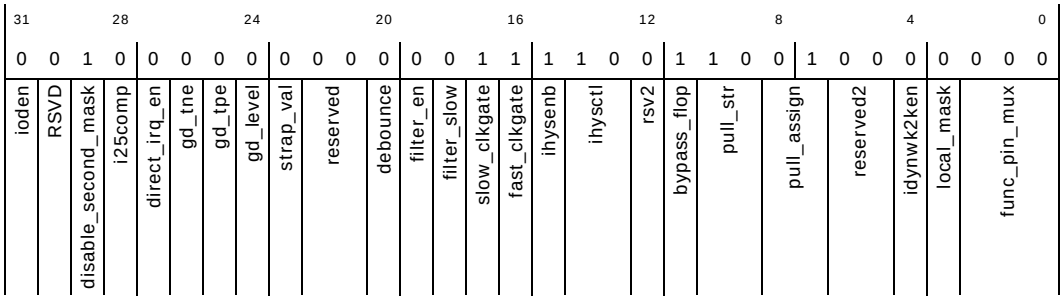
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

cfio_regs_pad_usb_oc1_b_PCONF0: [IOBASE + 2000h] + 0h

IOBASE Type: PCI Configuration Register (Size: 32 bits)
IOBASE Reference: [B:0, D:31, F:0] + 4Ch

Default: 2003CC80h



Bit Range	Default & Access	Description
31	0b RW	**Ioden (ioden):** Open Drain enable. Active high. Voltage domain: vcccore_1p0
30	0b RO	**Reserved (RSVD):** Reserved.
29	1b RW	**Disable Second Mask (disable_second_mask):** This bit will disable second mask when PB_CONFIG all_func_mask is used. The second mask is for changing the pull and the direction of the pad in different cycles. Please refer to the GPIO HAS for details.
28	0b RO	**I25comp (i25comp):** 25 ohm compensation of hflvt buffers
27	0b RW	**Direct Irq En (direct_irq_en):** If this bit is set, interrupt will used direct wire and not shared. This bit should be cleared if io access mode is selected for this pad
26	0b RW	**Gd Tne (gd_tne):** Negative edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active low level irq
25	0b RW	**Gd Tpe (gd_tpe):** Positive edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active high level irq
24	0b RW	**Gd Level (gd_level):** When this bit is set a level irq will be choosed and not edge irq
23	0b RO	**Strap Val (strap_val):** If strap pin exist, this bit will reflect its value even if overriden with DFT value
22:21	0h RO	**Reserved (reserved):** reserved
20	0b RO	**Debounce (debounce):** Enabling the debouncer for this pad. Debounce time will be according to the community setting at the debouce control register
19	0b RW	**Filter En (filter_en):** Enabling the glitch filter

Bit Range	Default & Access	Description
18	0b RW	**Filter Slow (filter_slow):** Use RTC clock for unglitch filter. This bit is reserved if unglitch filter does not exist for this pad
17	1b RW	**Slow Clkgate (slow_clkgate):** 1 Enables the glitch filter slow clock
16	1b RW	**Fast Clkgate (fast_clkgate):** 1 Enables the glitch filter fast clock
15	1b RO	**Ihysenb (ihysenb):** Hysteresis enable, active low
14:13	10b RW	**Ihysctl (ihysctl):** Hysteresis control
12	0b RO	**Rsv2 (rsv2):** reserved
11	1b RO	**Bypass Flop (bypass_flop):** 1 - Bypass pad controller I/O flops (if exists) 0 - Flop enabled if exists.
10:9	10b RW	**Pull Str (pull_str):** Pull strength: 00 - 2K 01 - 10K 10 - 20K 11 - 40K
8:7	01b RW	**Pull Assign (pull_assign):** Pull assignment: 00 - Non pull 01 - Pull Up 10 - Pull down 11 - reserved
6:5	00b RO	**Reserved2 (reserved2):** reserved
4	0b RW	**Idynwk2ken (idynwk2ken):** reduce weak 2kohm pull contention current when other chip driving
3	0b RO	**Local Mask (local_mask):** reserved
2:0	000b RW	**Func Pin Mux (func_pin_mux):** Func_Pin_Mux: Functional Pin Muxing Default function is always 0. These 3 bits are setting the memory function. The func_pin_mux function is masked by all_func_mask bit at the PB_CONFIG register. When IO_USE_SEL is set the pad will choose the GPIO function. function 0 is USB_OC1_B function 1 is GPIOS_20

39.9.2 Usb Oc1 B Delay Line Multiplexer (cfio_regs_pad_usb_oc1_b_PCONF1)—Offset 4h

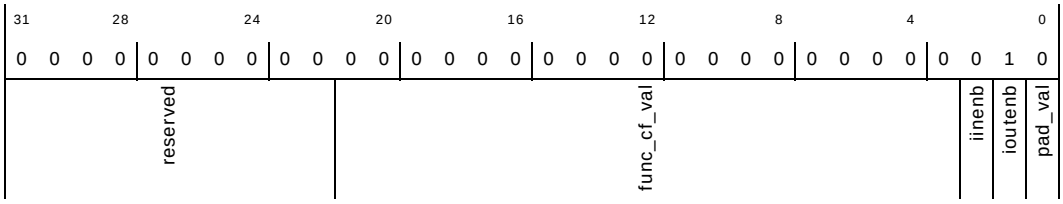
Default: 00000002h



Bit Range	Default & Access	Description
31:22	0h RO	**Reserved (reserved):** reserved
21:3	0h RO	**Func Cf Val (func_cf_val):** c and f values for the function delay, first 15 bits are c value and 4 msb are the f value
2	0b RW	**Iinenb (iinenb):** input enable - active low
1	1b RW	**Ioutenb (ioutenb):** output enable - active low
0	0b WO	**Pad Val (pad_val):** These registers are implemented as dual read/write with dedicated storage each. This is the same register as GP_LVL for IO space. (may be overridden and inaccessible to memory region write by legacy write) - default value can be both high or low. When the register is read it is reading the pad value. When pad is written it writes the pad value only if it is output enable and it is a gpio function

Bit Range	Default & Access	Description
31:22	0h RO	**Reserved (reserved):** reserved
21:3	0h RO	**Func Cf Val (func_cf_val):** c and f values for the function delay, first 15 bits are c value and 4 msb are the f value
2	0b RW	**Iinenb (iinenb):** input enable - active low
1	1b RO	**Ioutenb (ioutenb):** output enable - active low
0	0b WO	**Pad Val (pad_val):** These registers are implemented as dual read/write with dedicated storage each. This is the same register as GP_LVL for IO space. (may be overridden and inaccessible to memory region write by legacy write) - default value can be both high or low. When the register is read it is reading the pad value. When pad is written it writes the pad value only if it is output enable and it is a gpio function

Bit Range	Default & Access	Description
31	0b RW	**Ioden (ioden):** Open Drain enable. Active high. Voltage domain: vcccore_1p0
30	0b RO	**Reserved (RSVD):** Reserved.
29	1b RW	**Disable Second Mask (disable_second_mask):** This bit will disable second mask when PB_CONFIG all_func_mask is used. The second mask is for changing the pull and the direction of the pad in different cycles. Please refer to the GPIO HAS for details.
28	0b RO	**I25comp (i25comp):** 25 ohm compensation of hflvt buffers
27	0b RW	**Direct Irq En (direct_irq_en):** If this bit is set, interrupt will used direct wire and not shared. This bit should be cleared if io access mode is selected for this pad
26	0b RW	**Gd Tne (gd_tne):** Negative edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active low level irq
25	0b RW	**Gd Tpe (gd_tpe):** Positive edge detect for general detect event. 0 - No falling edge detect. 1 - Detect rising edge. (may be overridden and inaccessible to memory region write by legacy write). For level interrupt mode it will enable active high level irq
24	0b RW	**Gd Level (gd_level):** When this bit is set a level irq will be choosed and not edge irq
23	0b RO	**Strap Val (strap_val):** If strap pin exist, this bit will reflect its value even if overriden with DFT value
22:21	0h RO	**Reserved (reserved):** reserved
20	0b RO	**Debounce (debounce):** Enabling the debouncer for this pad. Debounce time will be according to the community setting at the debouce control register
19	0b RW	**Filter En (filter_en):** Enabling the glitch filter
18	0b RW	**Filter Slow (filter_slow):** Use RTC clock for unglitch filter. This bit is reserved if unglitch filter does not exist for this pad
17	1b RW	**Slow Clkgate (slow_clkgate):** 1 Enables the glitch filter slow clock
16	1b RW	**Fast Clkgate (fast_clkgate):** 1 Enables the glitch filter fast clock
15	1b RO	**Ihysenb (ihysenb):** Hysteresis enable, active low
14:13	10b RW	**Ihysctl (ihysctl):** Hysteresis control
12	0b RO	**Rsv2 (rsv2):** reserved
11	1b RO	**Bypass Flop (bypass_flop):** 1 - Bypass pad controller I/O flops (if exists) 0 - Flop enabled if exists.
10:9	10b RW	**Pull Str (pull_str):** Pull strength: 00 - 2K 01 - 10K 10 - 20K 11 - 40K
8:7	01b RW	**Pull Assign (pull_assign):** Pull assignment: 00 - Non pull 01 - Pull Up 10 - Pull down 11 - reserved
6:5	00b RO	**Reserved2 (reserved2):** reserved

Bit Range	Default & Access	Description
4	0b RW	**Idynwk2ken (idynwk2ken):** reduce weak 2kohm pull contention current when other chip driving
3	0b RO	**Local Mask (local_mask):** reserved
2:0	000b RW	**Func Pin Mux (func_pin_mux):** Func_Pin_Mux: Functional Pin Muxing Default function is always 0. These 3 bits are setting the memory function. The func_pin_mux function is masked by all_func_mask bit at the PB_CONFIG register. When IO_USE_SEL is set the pad will choose the GPIO function. function 0 is GPIOS_42 function 1 is USB_ULPI_0_STP function 2 is USH_HBP[0] function 3 is MCSI_LPDEBUG[4] For this function, software should make sure it changes the default pull from up to down. pull assign field, bits [8:7] should be set to 2'b10

31:19	0000h RO	**Reserved (reserved):** reserved
18	1b RW	**Ircclk En (ircclk_en):** This is enabling the rcomp clock. When rcomp clock is gated, rcomp reset is forced too, so when it is ungated again it will compensate
17:16	11b RW	**Ircintclkperiod (ircintclkperiod):** reserved
15	1b RW	**Ircen (ircen):** Enable RCOMP state machine for periodic RCOMP mode. This has to be enabled throughout periodic mode .0 state machine disabled 1 state machine enabled (default)
14:11	0000b RW	**Ircintsel (ircintsel):** Interval select this will select the periodic RCOMP update interval. All are periodic mode except 0000 option. 0000 non-periodic mode 0.5ms - 0001 1ms 0010 2ms 0011 3ms - 0100 4ms - 0101 5ms - 0110 10ms 0111 (Defaul) 15ms - 1000 25ms - 1001 50ms - 1010 100ms - 1011 200ms 1100 500ms - 1101 1000ms - 1110 2000ms - 1111 (non-periodic mode RCOMP update is not automatically triggered after the initial RCOMP cycle)
10	0b RW	**Ircforce (ircforce):** Force rcomp. only valid during non-periodic mode. RCOMP SM will trigger upon this signal goes high, so need first to clear it, and then set it high
9	0b RW	**Ircfreeze (ircfreeze):** Freeze rcomp. only valid during periodic mode. Setting this bit to 1 will stop the RCOMP S/M by stopping and clearing the 1ms and 10ms counter. Clearing it (0) would enable 1ms and 10ms counter again.
8:7	01b RW	**Ircstpcal (ircstpcal):** Stop calibration option. RCOMP SM (pullup and pulldown) will finish calibrating once orcpupen/orcpdnen toggle/s. The toggling would indicate the compensation value has been reached. This options is programmable for toggle once (single edge), toggle twice (double edge), toggle thrice (triple edge) or forcing it to finish after a certain cycle (defined by ircstpcyc input). 00 single edge detect (10 or 01) 01 double egde detect (101 or 010) (default) 10 triple edge detect (1010 or 0101) 11 stop after x cycles (depending on ircompstpcyc[3:0] value -- This is meant for debug) Default is 01 (double edge detect 101 or 010)
6:3	0000b RW	**Ircstpcyc (ircstpcyc):** Number of cycles calibration would be going through before stopping.0000 0 cycle 0001 1 cycle 0010 2 cycles ..... 1110 14 cycles 1111 15 cycles (maximum allowed with this options) valid only when ircompstpcal[1:0]=2b11. This is meant for debug.
2	0b RW	**Ircoen (ircoen):** Override enable. Setting this bit would allow system to go and override RCOMP value with data from config registers (which will drive ircpuov and ircpdov)
1	0b RW	**Ircoload (ircoload):** Do override now. only valid with ircoen enabled. once this bit is set, data from ircpuov and ircpdov will be loaded into each buffer
0	0b RW	**Ircdfx Select (ircdfx_select):** Bypass RCOMP calibration values and use DFX values instead. Setting this bit (1) would let ircdfx_pstr and ircdfx_nstr value loaded into all buffers.

40 PCU - iLB - Interrupt Decoding & Routing

The interrupt decoder is responsible for receiving interrupt messages from other devices in the SoC and decoding them for consumption by the interrupt router, the PCU - iLB - 8259 Programmable Interrupt Controllers (PIC) and/or the PCU - iLB - IO APIC.

The interrupt router is responsible for mapping each incoming interrupt to the appropriate PIRQx, for consumption by the PCU - iLB - 8259 Programmable Interrupt Controllers (PIC) and/or PCU - iLB - IO APIC.

40.1 Features

40.1.1 Interrupt Decoder

The interrupt decoder receives interrupt messages from devices in the SoC. These interrupts can be split into two primary groups:

- For consumption by the interrupt router
- For consumption by the 8259 PIC

40.1.1.1 For Consumption by the Interrupt Router

When a PCI-mapped device in the SoC asserts or de-asserts an INT[A:D] interrupt, an interrupt message is sent to the decoder. This message is decoded to indicate to the interrupt router which specific interrupt is asserted or de-asserted and which device the INT[A:D] interrupt originated from.

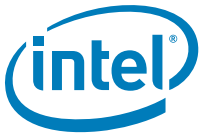
40.1.1.2 For Consumption by the 8259 PIC

When a device in the SoC asserts or de-asserts a legacy interrupt (IRQ), an interrupt message is sent to the decoder. This message is decoded to indicate to the 8259 PIC, which specific interrupt (IRQ[3, 4, 14 or 15]) was asserted or de-asserted.

40.1.2 Interrupt Router

The interrupt router aggregates the INT[A:D] interrupts for each PCI-mapped device in the SoC, received from the interrupt decoder, and the INT[A:D] interrupts direct from the Serialized IRQ controller. It then maps these aggregated interrupts to 8 PCI based interrupts: PIRQ[A:H]. This mapping is configured using the IR[31:0] registers.

PCI based interrupts PIRQ[A:H] are then available for consumption by either the 8259 PICs or the IO-APIC, depending on the configuration of the 8 PIRQx Routing Control Registers: PIRQA, PIQRB, PIRQC, PIRQD, PIRQE, PIRQF, PIRQG, PIRQH.



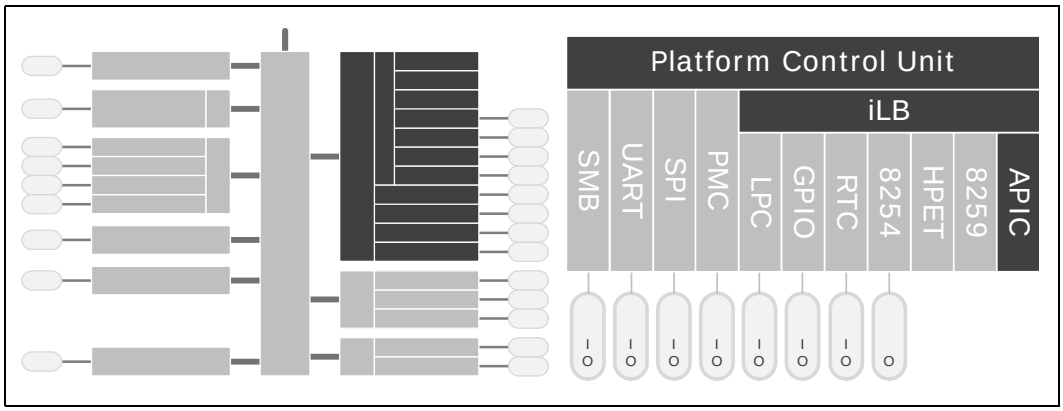
40.1.2.1 Routing PCI Based Interrupts to 8259 PIC

The interrupt router can be programmed to allow PIRQA-PIRQH to be routed internally to the 8259 as ISA compatible interrupts IRQ 3–7, 9–12 & 14–15. The assignment is programmable through the 8 PIRQx Routing Control Registers: PIRQA, PIQRB, PIRQC, PIRQD, PIRQE, PIRQF, PIRQG, PIRQH. One or more PIRQs can be routed to the same IRQ input. If ISA Compatible Interrupts are not required, the Route registers can be programmed to disable steering.

The PIRQx# lines are defined as active low, level sensitive. When a PIRQx# is routed to specified IRQ line, software must change the IRQ's corresponding ELCR bit to level sensitive mode. The SoC internally inverts the PIRQx# line to send an active high level to the PIC. When a PCI interrupt is routed onto the PIC, the selected IRQ can no longer be used by an active high device (through SERIRQ). However, active low interrupts can share their interrupt with PCI interrupts.

41 PCU - iLB - IO APIC

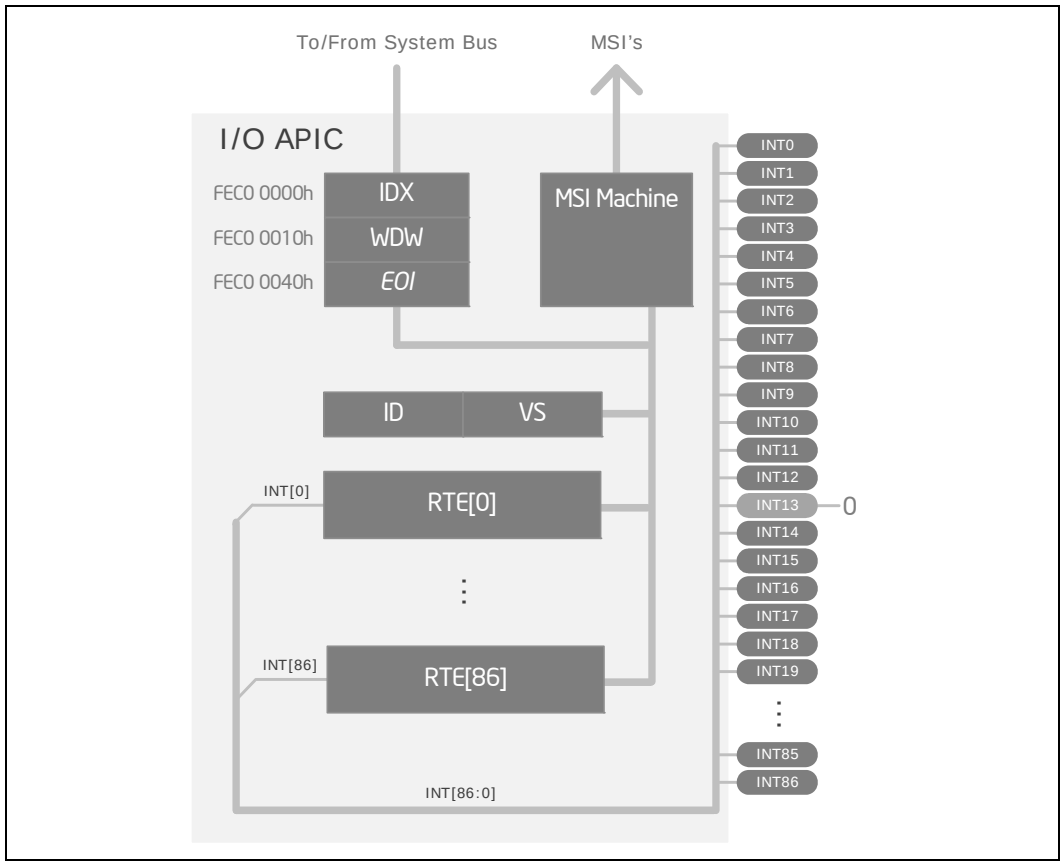
The IO Advanced Programmable Interrupt Controller (APIC) is used to support line interrupts more flexibly than the 8259 PIC. Line interrupts are routed to it from multiple sources, including legacy devices, via the interrupt decoder and serial IRQs, or they are routed to it from the interrupt router in the iLB. These line based interrupts are then used to generate interrupt messages targeting the local APIC in the processor.



41.1 Features

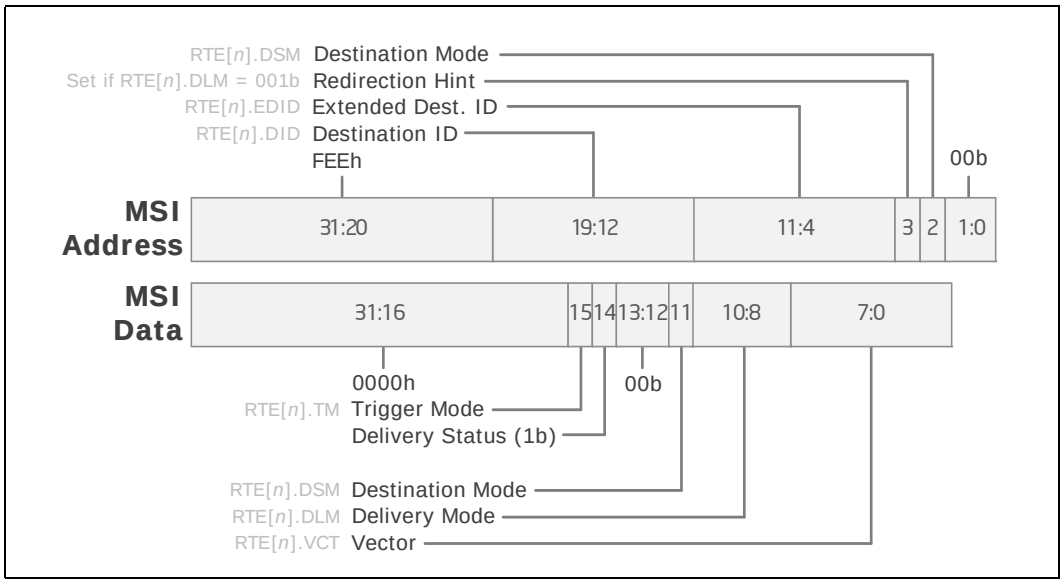
- 87 interrupt lines
  - IRQ0-86
- Edge or level trigger mode per interrupt
- Active low or high polarity per interrupt
- Works with local APIC in processor via MSIs
- MSIs can target specific processor core
- Established APIC programming model

Figure 140.Detailed Block Diagram



MSIs generated by the I/O APIC are sent as 32-bit memory writes to the Local APIC. The address and data of the write transaction are used as follows.

Figure 141.MSI Address and Data



Destination ID (DID) and Extended Destination ID (EDID) are used to target a specific processor core's local APIC.

41.2 Use

The I/O APIC contains indirectly accessed I/O APIC registers and normal memory mapped registers. There are three memory mapped registers:

- Index Register (IDX)
- Window Register (WDW)
- End Of Interrupt Register (EOI)

The Index register selects an indirect I/O APIC register (ID/VS/RTE[*n*]) to appear in the Window register.

The Window register is used to read or write the indirect register selected by the Index register.

The EOI register is written to by the Local APIC in the processor. The I/O APIC compares the lower eight bits written to the EOI register to the Vector set for each interrupt (RTE.VCT). All interrupts that match this vector will have their RTE.RIRR register cleared. All other EOI register bits are ignored.

41.5 Indirect I/O APIC Registers

These registers are selected with the IDX register, and read/written through the WDW register. Accessing these registers must be done as DW requests, otherwise unspecified behavior will result. Software should not attempt to write to reserved registers. Reserved registers may return non-zero values when read.

Note: There is one pair of redirection (RTE) registers per interrupt line. Each pair forms a 64-bit RTE register.

Note: Specified offsets should be placed in IDX, not added to IDX.

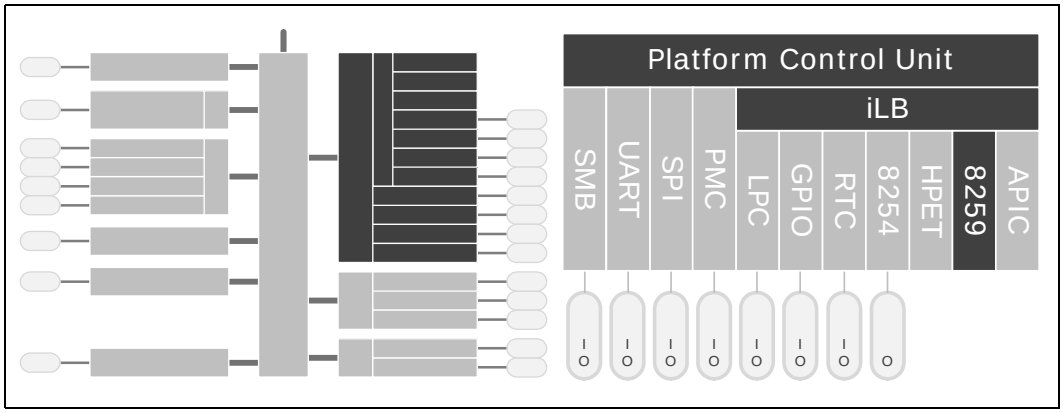
42 PCU - iLB - 8259 Programmable Interrupt Controllers (PIC)

The SoC provides an ISA-compatible programmable interrupt controller (PIC) that incorporates the functionality of two, cascaded 8259 interrupt controllers.



42.1 Features

In addition to providing support for ISA compatible interrupts, this interrupt controller can also support PCI based interrupts (PIRQs) by mapping the PCI interrupt onto a compatible ISA interrupt line. Each 8259 controller supports eight interrupts, numbered 0–7. Table 331 shows how the controllers are connected.

Note: The SoC does not implement any external PIRQ# signals. The PIRQs referred to in this chapter originate from the interrupt routing unit.

Table 331. Interrupt Controller Connections (Sheet 1 of 2)

8259	8259 Input	Connected Pin / Function
Master	0	Internal Timer / Counter 0 output or HPET #0; determined by GCFG.LRE register bit

	2	Slave controller INTR output
	3	IRQ3 via SERIRQ, PIRQx or PCU UART 1
	4	IRQ4 via SERIRQ or PIRQx
	5	IRQ5 via SERIRQ or PIRQx
	6	IRQ6 via SERIRQ or PIRQx
	7	IRQ7 via SERIRQ or PIRQx

Slave	0	Inverted IRQ8# from internal RTC or HPET
	1	IRQ9 via SERIRQ, SCI or PIRQx
	2	IRQ10 via SERIRQ, SCI or PIRQx
	3	IRQ11 via SERIRQ, SCI, HPET or PIRQx
	4	IRQ12 via SERIRQ, PIRQx or mouse emulation
	5	None
	6	PIRQx or IRQ14 from SATA controller
	7	IRQ15 via SERIRQ or PIRQx or IRQ15 from SATA controller

The SoC cascades the slave controller onto the master controller through master controller interrupt input 2. This means there are only 15 possible interrupts for the SoC PIC.

Interrupts can be programmed individually to be edge or level, except for IRQ0, IRQ2 and IRQ8#.

Note: Active-low interrupt sources (such as a PIRQ#) are inverted inside the SoC. In the following descriptions of the 8259s, the interrupt levels are in reference to the signals at the internal interface of the 8259s, after the required inversions have occurred. Therefore, the term “high” indicates “active,” which means “low” on an originating PIRQ#.

42.1.1 Interrupt Handling

42.1.1.1 Generating Interrupts

The PIC interrupt sequence involves three bits, from the IRR, ISR, and IMR, for each interrupt level. These bits are used to determine the interrupt vector returned, and status of any other pending interrupts. Table 332 defines the IRR, ISR, and IMR.

Table 332. Interrupt Status Registers

Bit	Description
IRR	**Interrupt Request Register.** This bit is set on a low to high transition of the interrupt line in edge mode, and by an active high level in level mode.
ISR	**Interrupt Service Register.** This bit is set, and the corresponding IRR bit cleared, when an interrupt acknowledge cycle is seen, and the vector returned is for that interrupt.
IMR	**Interrupt Mask Register.** This bit determines whether an interrupt is masked. Masked interrupts will not generate INTR.

42.1.1.2 Acknowledging Interrupts

The processor generates an interrupt acknowledge cycle that is translated into a Interrupt Acknowledge Cycle to the SoC. The PIC translates this command into two internal INTA# pulses expected by the 8259 controllers. The PIC uses the first internal INTA# pulse to freeze the state of the interrupts for priority resolution. On the second INTA# pulse, the master or slave sends the interrupt vector to the processor with the acknowledged interrupt code. This code is based upon the ICW2.IVBA bits, combined with the ICW2.IRL bits representing the interrupt within that controller.

Note: References to ICWx and OCWx registers are relevant to both the master and slave 8259 controllers.

Table 333. Content of Interrupt Vector Byte

Master, Slave Interrupt	Bits [7:3]	Bits [2:0]
IRQ7,15	ICW2.IVBA	111
IRQ6,14		110
IRQ5,13		101
IRQ4,12		100
IRQ3,11		011
IRQ2,10		010
IRQ1,9		001
IRQ0,8		000

42.1.1.3 Hardware/Software Interrupt Sequence

1. One or more of the Interrupt Request lines (IRQ) are raised high in edge mode, or seen high in level mode, setting the corresponding IRR bit.
2. The PIC sends INTR active to the processor if an asserted interrupt is not masked.
3. The processor acknowledges the INTR and responds with an interrupt acknowledge cycle.
4. Upon observing the special cycle, the SoC converts it into the two cycles that the internal 8259 pair can respond to. Each cycle appears as an interrupt acknowledge pulse on the internal INTA# pin of the cascaded interrupt controllers.
5. Upon receiving the first internally generated INTA# pulse, the highest priority ISR bit is set and the corresponding IRR bit is reset. On the trailing edge of the first pulse, a slave identification code is broadcast by the master to the slave on a private, internal three bit wide bus. The slave controller uses these bits to determine if it must respond with an interrupt vector during the second INTA# pulse.
6. Upon receiving the second internally generated INTA# pulse, the PIC returns the interrupt vector. If no interrupt request is present because the request was too short in duration, the PIC returns vector 7 from the master controller.

7. This completes the interrupt cycle. In AEOI mode the ISR bit is reset at the end of the second INTA# pulse. Otherwise, the ISR bit remains set until an appropriate EOI command is issued at the end of the interrupt subroutine.

42.1.2 Initialization Command Words (ICWx)

Before operation can begin, each 8259 must be initialized. In the SoC, this is a four byte sequence. The four initialization command words are referred to by their acronyms: ICW1, ICW2, ICW3, and ICW4.

The base address for each 8259 initialization command word is a fixed location in the I/O memory space: 20h for the master controller, and A0h for the slave controller.

42.1.2.1 ICW1

A write to the master or slave controller base address with data bit 4 equal to 1 is interpreted as a write to ICW1. Upon sensing this write, the PIC expects three more byte writes to 21h for the master controller, or A1h for the slave controller, to complete the ICW sequence.

A write to ICW1 starts the initialization sequence during which the following automatically occur:

1. Following initialization, an interrupt request (IRQ) input must make a low-to-high transition to generate an interrupt.
2. The Interrupt Mask Register is cleared.
3. IRQ7 input is assigned priority 7.
4. The slave mode address is set to 7.
5. Special mask mode is cleared and Status Read is set to IRR.

42.1.2.2 ICW2

The second write in the sequence (ICW2) is programmed to provide bits [7:3] of the interrupt vector that will be released during an interrupt acknowledge. A different base is selected for each interrupt controller.

42.1.2.3 ICW3

The third write in the sequence (ICW3) has a different meaning for each controller.

- For the master controller, ICW3 is used to indicate which IRQ input line is used to cascade the slave controller. Within the SoC, IRQ2 is used. Therefore, MICW3.CCC is set to a 1, and the other bits are set to 0s.
- For the slave controller, ICW3 is the slave identification code used during an interrupt acknowledge cycle. On interrupt acknowledge cycles, the master controller broadcasts a code to the slave controller if the cascaded interrupt won arbitration on the master controller. The slave controller compares this

identification code to the value stored in its ICW3, and if it matches, the slave controller assumes responsibility for broadcasting the interrupt vector.

42.1.2.4 ICW4

The final write in the sequence (ICW4) must be programmed for both controllers. At the very least, ICW4.MM must be set to a 1 to indicate that the controllers are operating in an Intel Architecture-based system.

42.1.3 Operation Command Words (OCW)

These command words reprogram the Interrupt controller to operate in various interrupt modes.

- OCW1 masks and unmasks interrupt lines.
- OCW2 controls the rotation of interrupt priorities when in rotating priority mode, and controls the EOI function.
- OCW3 sets up ISR/IRR reads, enables/disables the special mask mode (SMM), and enables/disables polled interrupt mode.

42.1.4 Modes of Operation

42.1.4.1 Fully Nested Mode

In this mode, interrupt requests are ordered in priority from 0 through 7, with 0 being the highest. When an interrupt is acknowledged, the highest priority request is determined and its vector placed on the bus. Additionally, the ISR for the interrupt is set. This ISR bit remains set until: the processor issues an EOI command immediately before returning from the service routine; or if in AEOI mode, on the trailing edge of the second INTA#. While the ISR bit is set, all further interrupts of the same or lower priority are inhibited, while higher levels generate another interrupt.

Interrupt priorities can be changed in the rotating priority mode.

42.1.4.2 Special Fully-Nested Mode

This mode is used in the case of a system where cascading is used, and the priority has to be conserved within each slave. In this case, the special fully-nested mode is programmed to the master controller. This mode is similar to the fully-nested mode with the following exceptions:

- When an interrupt request from a certain slave is in service, this slave is not locked out from the master's priority logic and further interrupt requests from higher priority interrupts within the slave are recognized by the master and initiate interrupts to the processor. In the normal-nested mode, a slave is masked out when its request is in service.
- When exiting the Interrupt Service routine, software has to check whether the interrupt serviced was the only one from that slave. This is done by sending a Non-

Specific EOI command to the slave and then reading its ISR. If it is 0, a non-specific EOI can also be sent to the master.

42.1.4.3 Automatic Rotation Mode (Equal Priority Devices)

In some applications, there are a number of interrupting devices of equal priority. Automatic rotation mode provides for a sequential 8-way rotation. In this mode, a device receives the lowest priority after being serviced. In the worst case, a device requesting an interrupt has to wait until each of seven other devices are serviced at most once.

There are two ways to accomplish automatic rotation using OCW2.REOI; the Rotation on Non-Specific EOI Command (OCW2.REOI=101b) and the rotate in automatic EOI mode which is set by (OCW2.REOI=100b).

42.1.4.4 Specific Rotation Mode (Specific Priority)

Software can change interrupt priorities by programming the bottom priority. For example, if IRQ5 is programmed as the bottom priority device, then IRQ6 is the highest priority device. The Set Priority Command is issued in OCW2 to accomplish this, where: OCW2.REOI=11xb, and OCW2.ILS is the binary priority level code of the bottom priority device.

In this mode, internal status is updated by software control during OCW2. However, it is independent of the EOI command. Priority changes can be executed during an EOI command by using the Rotate on Specific EOI Command in OCW2 (OCW2.REOI=111b) and OCW2.ILS=IRQ level to receive bottom priority.

42.1.4.5 Poll Mode

Poll mode can be used to conserve space in the interrupt vector table. Multiple interrupts that can be serviced by one interrupt service routine do not need separate vectors if the service routine uses the poll command. Poll mode can also be used to expand the number of interrupts. The polling interrupt service routine can call the appropriate service routine, instead of providing the interrupt vectors in the vector table. In this mode, the INTR output is not used and the microprocessor internal Interrupt Enable flip-flop is reset, disabling its interrupt input. Service to devices is achieved by software using a Poll command.

The Poll command is issued by setting OCW3.PMC. The PIC treats its next I/O read as an interrupt acknowledge, sets the appropriate ISR bit if there is a request, and reads the priority level. Interrupts are frozen from the OCW3 write to the I/O read. The byte returned during the I/O read contains a 1 in Bit 7 if there is an interrupt, and the binary code of the highest priority level in Bits 2:0.

42.1.4.6 Edge and Level Triggered Mode

In ISA systems this mode is programmed using ICW1.LTIM, which sets level or edge for the entire controller. In the SoC, this bit is disabled and a register for edge and level triggered mode selection, per interrupt input, is included. This is the Edge/Level control Registers ELCR1 and ELCR2.

If an ELCR bit is 0, an interrupt request will be recognized by a low-to-high transition on the corresponding IRQ input. The IRQ input can remain high without generating another interrupt. If an ELCR bit is 1, an interrupt request will be recognized by a high level on the corresponding IRQ input and there is no need for an edge detection. The interrupt request must be removed before the EOI command is issued to prevent a second interrupt from occurring.

In both the edge and level triggered modes, the IRQ inputs must remain active until after the falling edge of the first internal INTA#. If the IRQ input goes inactive before this time, a default IRQ7 vector is returned.

42.1.5 End of Interrupt (EOI) Operations

An EOI can occur in one of two fashions: by a command word write issued to the PIC before returning from a service routine, the EOI command; or automatically when the ICW4.AEOI bit is set to 1.

42.1.5.1 Normal End of Interrupt

In normal EOI, software writes an EOI command before leaving the interrupt service routine to mark the interrupt as completed. There are two forms of EOI commands: Specific and Non-Specific. When a Non-Specific EOI command is issued, the PIC clears the highest ISR bit of those that are set to 1. Non-Specific EOI is the normal mode of operation of the PIC within the SoC, as the interrupt being serviced currently is the interrupt entered with the interrupt acknowledge. When the PIC is operated in modes that preserve the fully nested structure, software can determine which ISR bit to clear by issuing a Specific EOI.

An ISR bit that is masked is not cleared by a Non-Specific EOI if the PIC is in the special mask mode. An EOI command must be issued for both the master and slave controller.

42.1.5.2 Automatic End of Interrupt Mode

In this mode, the PIC automatically performs a Non-Specific EOI operation at the trailing edge of the last interrupt acknowledge pulse. From a system standpoint, this mode should be used only when a nested multi-level interrupt structure is not required within a single PIC. The AEOI mode can only be used in the master controller and not the slave controller.

Note: Both the master and slave PICs have an AEOI bit: MICW4.AEOI and SICW4.AEOI respectively. Only the MICW4.AEOI bit should be set by software. The SICW4.AEOI bit should not be set by software.

42.1.6 Masking Interrupts

42.1.6.1 Masking on an Individual Interrupt Request

Each interrupt request can be masked individually by the Interrupt Mask Register (IMR). This register is programmed through OCW1. Each bit in the IMR masks one interrupt channel. Masking IRQ2 on the master controller masks all requests for service from the slave controller.

42.1.6.2 Special Mask Mode

Some applications may require an interrupt service routine to dynamically alter the system priority structure during its execution under software control. For example, the routine may wish to inhibit lower priority requests for a portion of its execution but enable some of them for another portion.

The special mask mode enables all interrupts not masked by a bit set in the Mask register. Normally, when an interrupt service routine acknowledges an interrupt without issuing an EOI to clear the ISR bit, the interrupt controller inhibits all lower priority requests. In the special mask mode, any interrupts may be selectively enabled by loading the Mask Register with the appropriate pattern.

The special mask mode is set by OCW3.ESMM=1b & OCW3.SMM=1b, and cleared where OCW3.ESMM=1b & OCW3.SMM=0b.

42.2 IO Mapped Registers

The interrupt controller registers are located at 20h and 21h for the master controller (IRQ0 - 7), and at A0h and A1h for the slave controller (IRQ8 - 13). These registers have multiple functions, depending upon the data written to them. Table 334 is a description of the different register possibilities for each address.

Note: The register descriptions after Table 334 represent one register possibility.

42.3.2 MICW2—Offset 21h

Master ICW2 is used to initialize the interrupt controller with the five most significant bits of the interrupt vector address. The value programmed for bits[7:3] is used by the CPU to define the base address in the interrupt vector table for the interrupt routines associated with each IRQ on the controller. Typical ISA ICW2 values are 08h for the master controller and 70h for the slave controller.

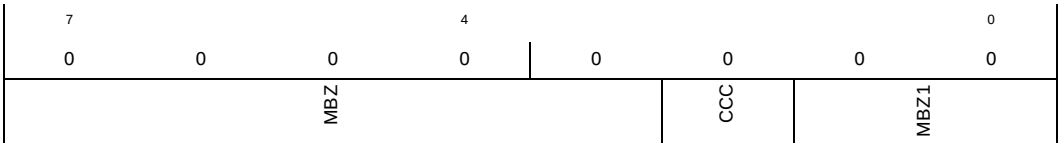
MICW3: 25h

Default: 00h



Bit Range	Default & Access	Description
7:3	X WO	**MBZ:** These bits must be programmed to zero.
2	X WO	**CCC:** Cascaded Controller Connection (CCC): This bit must always be programmed to a 1 to indicate the slave controller for interrupts 8 15 is cascaded on IRQ2.
1:0	X WO	**MBZ (MBZ1):** These bits must be programmed to zero.

42.3.5 MOCW3—Offset 28h

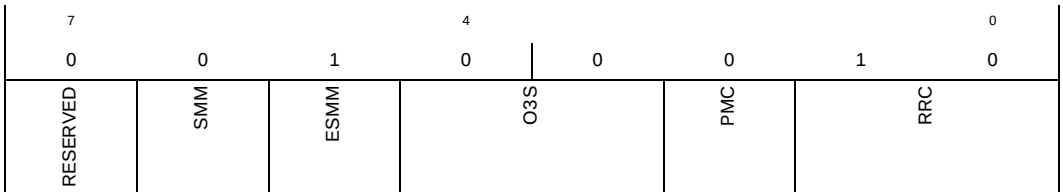
Master Operational Control Word 3

Access Method

Type: I/O Register
(Size: 8 bits)

MOCW3: 28h

Default: 22h



Bit Range	Default & Access	Description
7	0b RO	**RESERVED:** Reserved. Must be 0.
6	0b WO	**SMM:** Special Mask Mode (SMM): If this bit is set, the Special Mask Mode can be used by an interrupt service routine to dynamically alter the system priority structure while the routine is executing, through selective enabling/ disabling of the other channel's mask bits. Bit 6, the ESMM bit, must be set for this bit to have any meaning.
5	1b WO	**ESMM:** Enable Special Mask Mode (ESMM): When set, the SMM bit is enabled to set or reset the Special Mask Mode. When cleared, the SMM bit becomes a don't care.
4:3	X WO	**O3S:** OCW3 Select (O3S): When selecting OCW3, bits 4:3 = 01
2	X WO	**PMC:** Poll Mode Command (PMC): When cleared, poll command is not issued. When set, the next I/O read to the interrupt controller is treated as an interrupt acknowledge cycle. An encoded byte is driven onto the data bus, representing the highest priority level requesting service.
1:0	10b WO	**RRC:** Register Read Command (RRC): These bits provide control for reading the ISR and Interrupt IRR. When bit 1=0, bit 0 will not affect the register read selection. Following ICW initialization, the default OCW3 port address read will be read IRR. To retain the current selection (read ISR or read IRR), always write a 0 to bit 1 when programming this register. The selected register can be read repeatedly without reprogramming OCW3. To select a new status register, OCW3 must be reprogrammed prior to attempting the read. 00 No Action 01 No Action 10 Read IRQ Register 11 Read IS Register

42.3.6 MICW4—Offset 29h

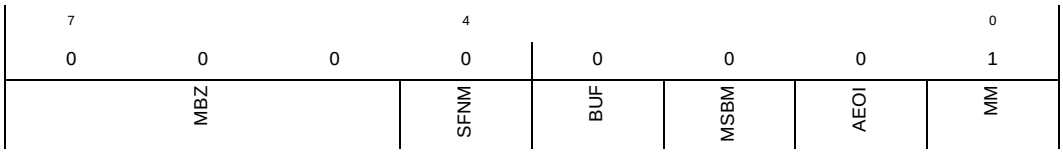
Master Initialization Command Word 4

Access Method

Type: I/O Register
(Size: 8 bits)

MICW4: 29h

Default: 01h



Bit Range	Default & Access	Description
7:5	X WO	**MBZ:** These bits must be programmed to zero.
4	0b WO	**SFNM:** Special Fully Nested Mode (SFNM): Should normally be disabled by writing a 0 to this bit. If SFNM=1, the special fully nested mode is programmed.

Bit Range	Default & Access	Description
3	0b WO	**BUF:** Buffered Mode (BUF): Must be cleared for non-buffered mode. Writing 1 will result in undefined behavior.
2	0b WO	**MSBM:** Master/Slave in Buffered Mode (MSBM): Not used. Should always be programmed to 0.
1	0b WO	**AEOI:** Automatic End of Interrupt (AEOI): This bit should normally be programmed to 0. This is the normal end of interrupt. If this bit is 1, the automatic end of interrupt mode is programmed.
0	1b WO	**MM:** Microprocessor Mode (MM): This bit must be written to 1 to indicate that the controller is operating in an Intel Architecture-based system. Writing 0 will result in undefined behavior.

42.3.7 MOCW1—Offset 2Dh

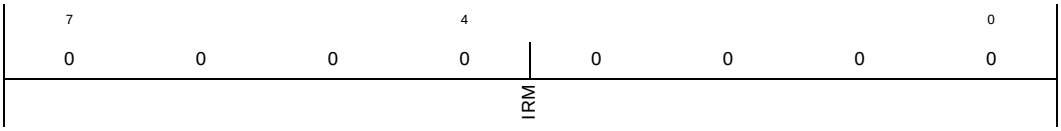
Master Operational Control Word 1 (Interrupt Mask)

Access Method

Type: I/O Register
(Size: 8 bits)

MOCW1: 2Dh

Default: 00h



Bit Range	Default & Access	Description
7:0	00h RW	**IRM:** Interrupt Request Mask (IRM): When a 1 is written to any bit in this register, the corresponding IRQ line is masked. When a 0 is written to any bit in this register, the corresponding IRQ mask bit is cleared, and interrupt requests will again be accepted by the controller. Masking IRQ2 on the master controller will also mask the interrupt requests from the slave controller.

42.3.8 SICW1—Offset A0h

Slave Initialization Command Word 1.A write to Initialization Command Word 1 starts the interrupt controller initialization sequence, during which the following occurs: * The Interrupt Mask register is cleared. * IRQ7 input is assigned priority 7. * The slave mode address is set to 7. * Special Mask Mode is cleared and Status Read is set to IRR. Once this write occurs, the controller expects writes to ICW2, ICW3, and ICW4 to complete the initialization sequence.

7:5	X WO	**MCS85:** These bits are MCS-85 specific, and not needed. Should be programmed to 000
4	X WO	**ICWOCWSEL:** ICW/OCW select: This bit must be a 1 to select ICW1 and enable the ICW2, ICW3, and ICW4 sequence.
3	X WO	**LTIM:** Edge/Level Bank Select (LTIM): Disabled. Replaced by ELCR1 and ELCR2.
2	X WO	**ADI:** ADI. Ignored for VLV. Should be programmed to 0.
1	X WO	**SNGL:** Single or Cascade (SNGL): Must be programmed to a 0 to indicate two controllers operating in cascade mode.
0	X WO	**IC4:** wICW4 Write Required (IC4): This bit must be programmed to a 1 to indicate that ICW4 needs to be programmed.

42.3.9 SICW2—Offset A1h

Slave ICW2 is used to initialize the interrupt controller with the five most significant bits of the interrupt vector address. The value programmed for bits[7:3] is used by the CPU to define the base address in the interrupt vector table for the interrupt routines associated with each IRQ on the controller. Typical ISA ICW2 values are 08h for the master controller and 70h for the slave controller.

Bit Range	Default & Access	Description
7:3	X WO	**IVBA:** Interrupt Vector Base Address: Bits [7:3] define the base address in the interrupt vector table for the interrupt routines associated with each interrupt request level input.
2:0	X WO	**IRL:** Interrupt Request Level: When writing ICW2, these bits should all be 0. During an interrupt acknowledge cycle, these bits are programmed by the interrupt controller with the interrupt to be serviced. This is combined with bits [7:3] to form the interrupt vector driven onto the data bus during the second INTA# cycle. The code is a three bit binary code: Code Master Interrupt Slave Interrupt 000 IRQ0 IRQ8 001 IRQ1 IRQ9 010 IRQ2 IRQ10 011 IRQ3 IRQ11 100 IRQ4 IRQ12 101 IRQ5 IRQ13 110 IRQ6 IRQ14 111 IRQ7 IRQ15
