

FEATURES

- 128 positions
- 10 kΩ, 50 kΩ, 100 kΩ
- 5 V to 30 V single-supply operation
- ±5 V to ±15 V dual-supply operation
- 3-wire SPI®-compatible serial interface
- THD 0.006% typical
- Programmable preset
- Power shutdown: less than 1 μA
- iCMOS™ process technology

APPLICATIONS

- High voltage DAC
- Programmable power supply
- Programmable gain and offset adjustment
- Programmable filters, delays
- Actuator control
- Audio volume control
- Mechanical potentiometer replacement

GENERAL DESCRIPTION

The AD7376¹ is one of the few high voltage, high performance digital potentiometers² in the market at present. This device can be used as a programmable resistor or resistor divider. The AD7376 performs the same electronic adjustment function as mechanical potentiometers, variable resistors, and trimmers with enhanced resolution, solid-state reliability, and programmability. With digital rather than manual control, AD7376 provides layout flexibility and allows close-loop dynamic controllability.

¹ Patent number: 54952455.

² The terms *digital potentiometer* and *RDAC* are used interchangeably.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

The AD7376 features sleep-mode programmability in shutdown that can be used to program the preset before device activation, thus providing an alternative to costly EEPROM solutions.

The AD7376 is available in 14-lead TSSOP and 16-lead wide body SOIC packages in 10 kΩ, 50 kΩ, and 100 kΩ options. All parts are guaranteed to operate over the -40°C to +85°C extended industrial temperature range.

AD7376

Parameter	Symbol	Conditions	Min	Typ ¹	Max	Unit
DYNAMIC CHARACTERISTICS ^{6, 9, 10}						
Bandwidth –3 dB	BW	Code = 0x40		470		kHz
Total Harmonic Distortion	THD _W	V _A = 1 V rms, V _B = 0 V, f = 1 kHz		0.006		%
V _W Settling Time	t _s	V _A = 10 V, V _B = 0 V, ±1 LSB error band		4		μs
Resistor Noise Voltage	e _{N_WB}	R _{WB} = 5 kΩ, f = 1 kHz		0.9		nV√Hz

¹ Typical values represent average readings at 25°C, V_{DD} = 15 V, and V_{SS} = –15 V.

² Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum and minimum resistance wiper positions. R-DNL measures the relative step change from an ideal value measured between successive tap positions. Parts are guaranteed monotonic.

³ Pb-free parts have a 35 ppm/°C temperature coefficient.

⁴ INL and DNL are measured at V_W with the RDAC configured as a potentiometer divider, similar to a voltage output digital-to-analog converter. V_A = V_{DD} and V_B = 0 V. DNL specification limits of ±1 LSB maximum are guaranteed monotonic operating conditions.

⁵ Resistor Terminals A, B, and W have no limitations on polarity with respect to each other.

⁶ Guaranteed by design and not subject to production test.

⁷ Measured at the A terminal. A terminal is open circuit in shutdown mode.

⁸ P_{DISS} is calculated from (I_{DD} × V_{DD}) + abs(I_{SS} × V_{SS}). CMOS logic level inputs result in minimum power dissipation.

⁹ Bandwidth, noise, and settling times are dependent on the terminal resistance value chosen. The lowest R value results in the fastest settling time and highest bandwidth. The highest R value results in the minimum overall power consumption.

¹⁰ All dynamic characteristics use V_{DD} = 15 V and V_{SS} = –15 V.

ELECTRICAL CHARACTERISTICS—50 kΩ, 100 kΩ VERSIONS

V_{DD}/V_{SS} = ±15 V ± 10% or ±5 V ± 10%, V_A = V_{DD}, V_B = V_{SS}/0 V, –40°C < T_A < +85°C, unless otherwise noted.

¹⁰ All dynamic characteristics use $V_{DD} = 15\text{ V}$ and $V_{SS} = -15\text{ V}$.

TIMING SPECIFICATIONS

Table 3.

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
INTERFACE TIMING CHARACTERISTICS^{1, 2}						
Clock Frequency	f_{CLK}	Clock level high or low			4	MHz
Input Clock Pulse Width	t_{CH}, t_{CL}		120			ns
Data Set-up Time	t_{DS}		30			ns
Data Hold Time	t_{DH}		20			ns
CLK to SDO Propagation Delay ³	t_{PD}	$R_{Pull-up} = 2.2\text{ k}\Omega, C_L < 20\text{ pF}$	10		100	ns
$\overline{CS}$ Set-up Time	t_{CSS}		120			ns
$\overline{CS}$ High Pulse Width	t_{CSW}		150			ns
Reset Pulse Width	t_{RS}		120			ns
CLK Fall to $\overline{CS}$ Fall Hold Time	t_{CSH0}		10			ns
CLK Rise to $\overline{CS}$ Rise Hold Time	t_{CSH}		120			ns
$\overline{CS}$ Rise to Clock Rise Setup	t_{CS1}		120			ns

¹ Guaranteed by design and not subject to production test.

² See Figure 3 for the location of the measured values. All input control voltages are specified with $t_R = t_F = 1\text{ ns}$ (10% to 90% of V_{DD}) and timed from a voltage level of 1.6 V. Switching characteristics are measured using $V_{DD} = 15\text{ V}$ and $V_{SS} = -15\text{ V}$.

³ Propagation delay depends on value of V_{DD} , $R_{Pull-up}$, and C_L .

Figure 3. Detail Timing Diagram

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 5.

Parameter	Rating
V_{DD} to GND	−0.3 V to +35 V
V_{SS} to GND	+0.3 V to −16.5 V
V_{DD} to V_{SS}	−0.3 V to +35 V
V_A, V_B, V_W to GND	V_{SS} to V_{DD}
Maximum Current	
I_{WB}, I_{WA} Pulsed	±20 mA
I_{WB} Continuous ($R_{WB} \leq 6\text{ k}\Omega$, A open, $V_{DD}/V_{SS} = 30\text{ V}/0\text{ V}$) ¹	±5 mA
I_{WA} Continuous ($R_{WA} \leq 6\text{ k}\Omega$, B open, $V_{DD}/V_{SS} = 30\text{ V}/0\text{ V}$) ¹	±5 mA
Digital Input and Output Voltages to GND	0 V to 7 V
Operating Temperature Range	−40°C to +85°C
Maximum Junction Temperature (T_{JMAX}) ²	150°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10 sec)	300°C
Package Power Dissipation	$(T_{JMAX} - T_A)/\theta_{JA}$
Thermal Resistance θ_{JA}	
16-Lead SOIC_W	120°C/W
14-Lead TSSOP	240°C/W

¹ Maximum terminal current is bound by the maximum current handling of the switches, maximum power dissipation of the package, and maximum applied voltage across any two of the A, B, and W terminals at a given resistance.

² Package power dissipation = $(T_{JMAX} - T_A)/\theta_{JA}$.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 4. 14-Lead TSSOP Pin Configuration

Figure 5. 16-Lead SOIC_W Pin Configuration

Table 6. Pin Function Descriptions

Pin No.		Mnemonic	Description
14-Lead TSSOP	16-Lead SOL		
1	1	A	A Terminal. $V_{SS} \leq V_A \leq V_{DD}$.
2	2	B	B Terminal. $V_{SS} \leq V_B \leq V_{DD}$.
3	3	V_{SS}	Negative Power Supply.
4	4	GND	Digital Ground.
5	5	$\overline{CS}$	Chip Select Input, Active Low. When $\overline{CS}$ returns high, data is loaded into the wiper register.
6	6	$\overline{RS}$	Reset to Midscale.
7	7	CLK	Serial Clock Input. Positive-edge triggered.
8	8, 9, 10	NC	No Connect. Let it float or ground.
9	11	SDI	Serial Data Input (data loads MSB first).
10	12	$\overline{SHDN}$	Shutdown. A terminal open ended; W and B terminals shorted. Can be used as programmable preset. ¹
11	13	SDO	Serial Data Output.
12	14	V_{DD}	Positive Power Supply.
13	15	NC	No Connect. Let it float or ground.
14	16	W	Wiper Terminal. $V_{SS} \leq V_W \leq V_{DD}$.

¹ Assert shutdown and program the device during power-up. Then deassert the shutdown to achieve the desirable preset level.

PROGRAMMING THE POTENTIOMETER DIVIDER

Voltage Output Operation

The digital potentiometer easily generates a voltage divider at Wiper W to Terminal B and Wiper W to Terminal A that is proportional to the input voltage at Terminal A to Terminal B. Unlike the polarity of V_{DD} to GND, which must be positive, voltage across Terminal A to Terminal B, Wiper W to Terminal A, and Wiper W to Terminal B can be at either polarity.

Figure 26. Potentiometer Mode Configuration

If ignoring the effect of the wiper resistance for the purpose of approximation, connecting the Terminal A to 30 V and the Terminal B to ground produces an output voltage at the Wiper W to Terminal B ranging from 0 V to 1 LSB less than 30 V. Each LSB of voltage is equal to the voltage applied across Terminals A and B divided by the 128 positions of the potentiometer divider. The general equation defining the output voltage at V_W with respect to ground for any valid input voltage applied to Terminals A and B is

$$V_W(D) = \frac{D}{128} V_A \quad (3)$$

A more accurate calculation that includes the effect of wiper resistance, V_W , is

$$V_W(D) = \frac{R_{WB}(D)}{R_{AB}} V_A + \frac{R_{WA}(D)}{R_{AB}} V_B \quad (4)$$

Operation of the digital potentiometer in the divider mode results in a more accurate operation over temperature. Unlike when in rheostat mode, the output voltage in divider mode is primarily dependent on the ratio, not the absolute values, of the internal resistors R_{WA} and R_{WB} . Therefore, the temperature drift reduces to 5 ppm/°C.

3-WIRE SERIAL BUS DIGITAL INTERFACE

The AD7376 contains a 3-wire digital interface ($\overline{CS}$, CLK, and SDI). The 7-bit serial word must be loaded MSB first. The format of the word is shown in Figure 2. The positive-edge sensitive CLK input requires clean transitions to avoid clocking incorrect data into the serial input register. Standard logic families work well. When $\overline{CS}$ is high, the clock loads data into the serial register upon each positive clock edge.

The data set-up and hold times in the specifications table determine the valid timing requirements. The AD7376 uses a 7-bit serial input data register word that is transferred to the internal RDAC register when the $\overline{CS}$ line returns to logic high. Extra MSB bits are ignored.

The AD7376 powers up at a random setting. However, the midscale preset or any desirable preset can be achieved by manipulating $\overline{RS}$ or $\overline{SHDN}$ with an extra I/O.

When the reset ($\overline{RS}$) pin is asserted, the wiper resets to the midscale value. Midscale reset can be achieved dynamically or during power-up if an extra I/O is used.

When the $\overline{SHDN}$ pin is asserted, the AD7376 opens SW_A to let the Terminal A float and to short Wiper W to Terminal B. The AD7376 consumes negligible power during the shutdown mode and resumes the previous setting once the $\overline{SHDN}$ pin is released. On the other hand, the AD7376 can be programmed with any settings during shutdown. With an extra programmable I/O asserting shutdown during power up, this unique feature allows the AD7376 with programmable preset at any desirable level.

Table 7 shows the logic truth table of all operation.

Table 7. Input Logic Control Truth Table¹

CLK	$\overline{CS}$	$\overline{RS}$	$\overline{SHDN}$	Register Activity
L	L	H	H	Enables SR, enables SDO pin.
P	L	H	H	Shifts one bit in from the SDI pin. The seventh previously entered bit is shifted out of the SDO pin.
X	P	H	H	Loads SR data into 7-bit RDAC latch.
X	H	H	H	No operation.
X	X	L	H	Sets 7-bit RDAC latch to midscale, wiper centered, and SDO latch cleared.
X	H	P	H	Latches 7-bit RDAC latch to 0x40.
X	H	H	L	Opens circuits resistor of Terminal A, connects Wiper W to Terminal B, turns off SDO output transistor.

¹ P = positive edge, X = don't care, and SR = shift register.

DAISY-CHAIN OPERATION

Figure 27. Detail SDO Output Schematic of the AD7376

Figure 27 shows the details of the serial data output pin (SDO). SDO shifts out the SDI content in the previous frame; therefore, it can be used for daisy-chaining multiple devices. The SDO pin contains an open-drain N-Channel MOSFET and requires a pull-up resistor if the SDO function is used. Users need to tie the SDO pin of one package to the SDI pin of the next package. For example, in Figure 28 if two AD7376s are daisy-chained, a total of 14 bits of data are required for each operation. The first set of seven bits goes to U2; the second set of seven bits goes to U1. $\overline{CS}$ should be kept low until all 14 bits are clocked into their respective serial registers. Then $\overline{CS}$ is pulled high to complete the operation. When daisy-chaining multiple devices, users may need to increase the clock period because the pull-up resistor and the capacitive loading at the SDO-SDI interface may induce a time delay to subsequent devices.

Figure 28. Daisy-Chain Configuration

ESD PROTECTION

All digital inputs are protected with a series input resistor and a Zener ESD structure shown in Figure 29. These structures apply to digital input pins $\overline{CS}$, CLK, SDI, SDO, $\overline{RS}$, and $\overline{SHDN}$.

Figure 29. Equivalent ESD Protection Circuit

All analog terminals are also protected by Zener ESD protection diodes, as shown in Figure 30.

Figure 30. Equivalent ESD Protection Analog Pins

TERMINAL VOLTAGE OPERATING RANGE

The AD7376 V_{DD} and V_{SS} power supplies define the boundary conditions for proper 3-terminal digital potentiometer operation. Applied signals present on Terminals A, B, and W that are more positive than V_{DD} or more negative than V_{SS} will be clamped by the internal forward-biased diodes (see Figure 30).

POWER-UP AND POWER-DOWN SEQUENCES

Because of the ESD protection diodes that limit the voltage compliance at Terminals A, B, and W (see Figure 30), it is important to power V_{DD}/V_{SS} before applying voltage to Terminals A, B, and W. Otherwise, the diodes are forward biased such that V_{DD}/V_{SS} are powered unintentionally and affect the system. Similarly, V_{DD}/V_{SS} should be powered down last. The ideal power-up sequence is in the following order: GND, V_{DD} , V_{SS} , digital inputs, and $V_A/V_B/V_W$. The order of powering V_A , V_B , V_W , and the digital inputs is not important, as long as they are powered after V_{DD}/V_{SS} .

LAYOUT AND POWER SUPPLY BIASING

It is a good practice to employ a compact, minimum lead-length layout design. The leads to the input should be as direct as possible, with a minimum conductor length. Ground paths should have low resistance and low inductance.

Similarly, it is also good practice to bypass the power supplies with quality capacitors. Low ESR (equivalent series resistance) 1 μF to 10 μF tantalum or electrolytic capacitors should be applied at the supplies to minimize transient disturbances and filter low frequency ripple. Figure 31 illustrates the basic supply bypassing configuration for the AD7376.

The ground pin of the AD7376 is a digital ground reference. To minimize the digital ground bounce, the AD7376 digital ground terminal should be joined remotely to the analog ground (see Figure 31).

Figure 31. Power Supply Bypassing

APPLICATIONS

HIGH VOLTAGE DAC

AD7376 can be configured as a high voltage DAC as high as 30 V. The circuit is shown in Figure 32. The output is

$$V_O(D) = \frac{D}{128} \left[1.2 \text{ V} \times \left(1 + \frac{R_2}{R_1} \right) \right] \quad (5)$$

Where D is the decimal code from 0 to 127.

Figure 32. High Voltage DAC

PROGRAMMABLE POWER SUPPLY

With a boost regulator such as ADP1611, AD7376 can be used as the variable resistor at the regulator's FB pin to provide the programmable power supply (see Figure 33). The output is

$$V_O = 1.23 \text{ V} \times \left(1 + \frac{(D/128) \cdot R_{AB}}{R_2} \right) \quad (6)$$

Note that the AD7376's V_{DD} is derived from the output. Initially $L1$ acts as a short, and V_{DD} is one diode voltage drop below +5 V. The output slowly establishes to the final value.

The AD7376 shutdown sleep-mode programming can be used to program a desirable preset level at power-up.

Figure 33. Programmable Power Supply

AUDIO VOLUME CONTROL

Because of its good THD performance and high voltage capability, AD7376 can be used as a digital volume control. If AD7376 is used directly as an audio attenuator or gain amplifier, a large step change in the volume level at any arbitrary time can lead to an abrupt discontinuity of the audio signal, causing an audible zipper noise. To prevent this, a zero-crossing window detector can be inserted to the $\overline{\text{CS}}$ line to delay the device update until the audio signal crosses the window. Since the input signal can operate on top of any dc levels rather than absolute zero volt level, zero-crossing in this case means the signal is ac-coupled and the dc offset level is the signal zero reference point. The configuration to reduce zipper noise and the result of using this configuration are shown in Figure 34 and Figure 35, respectively. The input is ac-coupled by C1 and attenuated down before feeding into the window comparator formed by U₂, U₃, and U_{4B}. U₆ is used to establish the signal zero reference. The upper limit of the comparator is set above its offset and, therefore, the output pulses high whenever the input falls between 2.502 V and 2.497 V (or 0.005 V window) in this example. This output is AND'd with the chip select signal such that the AD7376 updates whenever the signal crosses the window. To avoid constant update of the device, the chip select signal should be programmed as two pulses, rather than the one shown in Figure 2.

In Figure 35, the lower trace shows that the volume level changes from a quarter scale to full scale when a signal change occurs near the zero-crossing window.

The AD7376 shutdown sleep-mode programming feature can be used to mute the device at power up by holding SHDN low and programming zero scale.

Figure 34. Audio Volume Control with Zipper Noise Reduction

NOTES

1. THE LOWER TRACE SHOWS THAT THE VOLUME LEVEL CHANGES FROM QUARTER SCALE TO FULL SCALE, WITH THE CHANGE OCCURRING NEAR THE ZERO-CROSSING WINDOW.
